## Preface to Thirteenth Edition

The most noticeable physical change in this thirteenth edition of *Official Methods of Analysis of the Association of Official Analytical Chemists* ("The Book of Methods") is its size. A survey of users of the Book of Methods revealed an overwhelming desire to maintain the compendium as a single volume. The easiest way to do this was to increase the size of the page. Users also expressed a desire for a system that will keep the same reference number for a given method from edition to edition. A practical system that will maintain the continuity of the numbering system and the organizational structure of the methods within a chapter has not yet been devised.

Approximately 175 new methods have been added during the current five year period (1974–1978); 83 methods have been deleted, replaced, or supplused. The approval of an average of only 35 new methods per year represents a marked decline from the 70 per year of the four year period of the previous edition (1970–1973) and the 50 per year of the five year period of the tenth edition (1965–1969). The decline is undoubtedly the result of a number of factors. Chief among them are the greater complexity of modern methods, requiring a large investment in resources that is not readily mobilized to fit an Associate Referee's schedule; and the fact that government agencies are attempting to obtain compliance, especially of the newer statutes, by promulgation of regulations and by auditing rather than by laboratory examinations.

The greatest activity, as measured by approval of new methods, is in the field of pesticide formulations, partly as a result of the active implementation of the cooperative agreement with the Collaborative International Pesticide Analytical Council (CIPAC). Other active areas include extraneous materials, vitamins and other nutrients, dairy products, and microbiological methods. In fact, examination for and by biological constituents (filth, microbiological assays, and examination for food-borne pathogens) comprises approximately 17% of the new methods adopted.

A comparison of the types of methods adopted between this and the previous edition reveals that gas-liquid chromatography has overtaken spectrophotometry in its various forms (visible, ultraviolet, and fluorescent) as the most predominant quantitative technique in *Official Methods*. High pressure (or performance) liquid chromatography has spurted from none to 6% of the adopted methods within the relatively short period of five years. Electrometric methods (potentiometric, polarographic, and ion-selective) are now sufficiently numerous to deserve a separate category. Infrared methods are no longer a major factor in quantitation; they are now mainly used for identification and confirmation. A comparison of the present and previous editions is presented in Table 1. The figures given are only rough approximations because of the arbitrariness often required in classifying a method and in deciding when a new method or revision is sufficiently independent to warrant contributing to the statistics.

**Table 1. Classification of new methods approved by the AOAC in the thirteenth and twelfth editions**

Method classification	13th edition (1980)	12th edition (1975)
Gas-liquid chromatography	18%	14%
Spectrophotometry	16	20
Titrimetric	10	7
Filth, isolation	8	14
Automated	7	5
Biological and microbiological	9	8
High pressure liquid chromatography	6	—
Atomic absorption	4	9
Electrometric	5	—
Chromatography (thin layer, etc.)	3	3
Gravimetric	2	6
Miscellaneous (physical, qualitative, etc.)	11	13

The most interesting new collaboratively studied method is the mass spectrometric method for the detection of adulteration of honey with high fructose corn sirup. Corn sirups (from a monocotyledonous plant) have a distinctly different  $^{13}\text{C}/^{12}\text{C}$  ratio than sirups from most dicotyledonous plants, which are the source of most honeys. The isotope ratio mass spectrometer required for this determination is a highly specialized instrument, even in the field of mass spectrometry. Despite the rarity of the instrumentation, sufficient laboratories participated in the collaborative study to establish the reproducibility of the method.

A problem that has arisen is how to handle the numerous individual instruments of diverse design and manufacture that have been developed to automate a particular determination. Even if this problem is solved by incorporating all the available instruments into the initial collaborative study, the problem returns with the first "new and improved" modification. Different instrument designs and their subsequent modifications have been handled in the infrared determination of milk constituents by providing performance specifications which must be met by the basic instrument in general, when compared to a reference method or reference sample. In addition, the user must satisfy himself that his particular instrument also meets the performance specifications by frequent comparisons with the reference method or sample. This requirement eliminates the need for repeated collaborative studies every time a manufacturer redesigns or modifies his basic equipment, and in addition provides a continuous quality control technique on the performance of the instrument, method, and laboratory.

It should not be overlooked that automation is not confined to physical and chemical determinations. The microbiological chapter contains three collaboratively studied instrumental methods for somatic cell count and an instrumental method for distributing a liquid sample for plate counting. Biochemical diagnostic kits have also been evaluated collaboratively for their

effectiveness in identifying *Salmonella* and other enteric isolates.

A criticism that is often leveled at the AOAC validation mechanism is that it is too slow to keep up with the pace of requirements for methods by regulatory agencies and the regulated industry. This objection overlooks the point that the speed with which a method is validated is almost completely in the hands of those needing the validated method, rather than in the hands of the AOAC. The method must be tested for ruggedness, and the directions tested for clarity; samples must be prepared and distributed; laboratories must analyze the samples and report the results. Dubious results must be investigated and occasionally samples must be reanalyzed. The data must be tabulated and analyzed, and a report written. There is no way to short-cut the process of obtaining intra- and interlaboratory variability except to conduct the necessary experimental work and perform the necessary statistical calculations. Only then is the recommendation subject to the time restrictions of the AOAC mechanism. To ensure that the AOAC mechanism of annual approval is not holding up use of needed methods, a new temporary class of methods has been introduced entitled "Interim First Action." These are methods which, together with their supporting studies, have been received between annual meetings and have been sent through the customary reviewing procedure. To be designated Interim First Action, a method must have been approved by the appropriate Referee and Subcommittee, and by the Chairman of the Committee on Official Methods. The method only lacks the formal vote by those AOAC members having regulatory authority over the commodity involved. Such formal approval is usually provided at the next annual meeting, at which time the method becomes

"First Action." Approximately five interim methods are approved annually. Several such methods appear in this volume, depending upon the time of their submission and review in relation to the editorial status of the chapter to which they are assigned. The current status of these Interim First Action methods, as well as the status of any method, can be found by consulting the latest cumulative index to *Changes in Methods*, which appears as the final pages of each March issue of the Journal.

For those users of AOAC methods who may not be familiar with the procedures by which a method is included in this volume, we are reprinting a paper prepared for the Joint International Symposium, "The Harmonization of Collaborative Studies," held in London, England 9-10 March 1978. The document was drafted by the AOAC Committee on Collaborative Studies: Elwyn D. Schall, Chairman; Charles W. Gehrke, William Horwitz, Anthony J. Malonski, James P. Minyard, Jr., Forrest W. Quackenbush, and Ernest S. Windham. This paper appeared in *Analytical Chemistry* (March 1978), **50**, 337A-340A.

The publication of this "Book of Methods" is possible only because of the extensive cooperation of thousands of analysts who have volunteered to direct, participate in, and review the numerous collaborative studies that form the basis for inclusion of the several thousand methods that appear herein. Special recognition is due to Mrs. Betty Johnson who has prepared an entirely new index for this edition.

28 September, 1979

Editor

*Abstract from*

## Preface to First Edition

"In presenting this revision of the official and tentative methods of analysis of the Association of Official Agricultural Chemists, it is appropriate to give a brief statement of the organization of the Association, its purpose, and the procedure by which the methods are adopted.

"Membership in the Association is institutional and includes the State Departments of Agriculture, the State Agricultural Colleges and Experiment Stations, the Federal Department of Agriculture, and the Federal, State, and City offices charged with the enforcement of food, feed, drug, fertilizer, insecticide and fungicide control laws.

"The Association was founded at Philadelphia, Pa., September 9, 1884, by the following representative agricultural chemists of that time, the organization being the result of a series of informal meetings held the immediately preceding years:

"Prof. H. W. Wiley, Chemist of the Department of Agriculture, Washington, D.C.

Mr. Clifford Richardson, Assistant Chemist of the Department of Agriculture, Washington, D.C.

Mr. Philip E. Chazal, State Chemist of South Carolina.

Dr. Chas. W. Dabney, Jr., State Chemist of North Carolina.

Dr. W. J. Gascoyne, State Chemist of Virginia.

Dr. E. H. Jenkins, Connecticut Experiment Station.

Prof. John A. Meyers, State Chemist of Mississippi.

Prof. H. C. White, State Chemist of Georgia.

Mr. C. DeGhequier, Secretary National Fertilizer Association.

Dr. Schumann, Dr. Lehmann, Mr. Gaines and others."

# Collaborative Study Procedures of the Association of Official Analytical Chemists

The Association of Official Analytical Chemists (AOAC) is a unique, nonprofit scientific organization whose primary purpose is to serve the needs of government regulatory and research agencies for analytical methods. The goal of the Association is to provide methods which will perform with the necessary accuracy and precision under usual laboratory conditions (7). Since its formation in 1884 the AOAC has provided a mechanism to select methods of analysis from published literature or develop new methods, collaboratively test them through inter-laboratory studies, approve them, and publish the approved methods for a wide variety of materials relating to foods, drugs, cosmetics, agriculture, forensic science, and products affecting the public health and welfare. Its membership is composed of scientists from Federal, State, Provincial, and other regulatory bodies who work within the AOAC's established procedures as researchers, methods collaborators, and committee members. Although most of the members are from North America, many nations throughout the world are represented.

The AOAC has almost a century of experience in utilizing the collaborative study as a means of determining the reliability of analytical methods for general purposes and, especially, for regulatory purposes. In fact, the AOAC's major contribution to analytical science has been to bring the collaborative study technique for the validation of analytical methods to a high degree of perfection. In such a study, laboratories analyze identical sample sets which cover the range of applicability of a method previously selected as being useful and practical. The purpose of the study is to establish the characteristics of the methods with respect to accuracy, precision, sensitivity, range, specificity, limit of detection, limit of reliable measurement, selectivity, practicality, and similar attributes, as required.

## ORGANIZATION AND PROCEDURES FOR AOAC COLLABORATIVE STUDIES

The collaborative study is organized and directed by an analyst designated as the Associate Referee for the specific subject under investigation. Currently, some 600 Associate Referees appointed by the Association are responsible for as many topics. An Associate Referee is selected for his knowledge, interest, and experience in the subject matter field. He operates under the scientific guidance, support, and administrative supervision of a General Referee, who is in turn responsible for a product area. The Associate Referee reviews the literature and selects one or two of the better analytical methods available, modifying them as needed. Alternatively, he may develop or adapt a method used in his laboratory for the analyte and matrix under study, testing it thoroughly in his laboratory before designing a collaborative study. The General Referee is kept informed of such preliminary studies.

The samples analyzed in a collaborative study are normally prepared and distributed to the participants by the Associate Referee. The Association follows the recommendations of Youden (2) that not fewer than five laboratories participate and that a minimum of six sample materials be sent to each. These are

minima and, in practice, both are usually exceeded. In addition, a reference or practice sample is included, where possible.

Laboratories with at least some experience in the general subject matter are selected as collaborators. Because the objective of the study is to standardize the method, as contrasted to standardizing the analyst (3), all analysts are instructed to follow the method exactly as written even though they may not concur with the Associate Referee's selection among possible alternatives. The level of the analyte in the samples is usually unknown to the participants.

All individual results obtained by the collaborators are reported to the Associate Referee, who compiles and evaluates them. Since statistical treatment of the data is considered essential in a rigorous evaluation of the method for accuracy, precision, sensitivity, and specificity, it is now required for all studies. The Association considers this of such importance that it provides statistical assistance in all cases where it is otherwise unavailable to the Associate Referee. A statistical manual (4) is also provided.

The Associate Referee makes the initial judgment on the performance of the method. If he recommends approval, it passes to the General Referee and then to a committee of experts. If both recommend approval, the method is presented at the Association's annual business meeting for vote by the membership.

Approved methods and supporting data are published in the *Journal of the Association of Official Analytical Chemists*. They are subject to scrutiny and general testing by other analysts for at least a year before final adoption. They may be modified and restudied collaboratively as needed, should feedback from general use reveal flaws in the method or in its written set of directions. Approved methods are included in the Association's "Official Methods of Analysis", a book of some 1000 pages which is updated every 4–5 years.

The preceding summary of AOAC's *modus operandi* recognizes the need for healthy skepticism toward results obtained by analytical methods which have not undergone such rigorous scrutiny and interlaboratory testing of their accuracy, precision, dependability, specificity, and practicality.

## SELECTION OF METHODS FOR STUDY

A certain degree of variability is associated with all measurements. Much of the research on analytical chemistry is an attempt to minimize that variability. But there are many different types of variability in analytical work. We often find that when we attempt to minimize one kind, we must necessarily permit expansion in another kind. In practical analytical chemistry, the problem often comes down to which variability is to be minimized.

Some examples of this point may be helpful. In atomic weight determination, everything—especially *practicality*—is sacrificed for *accuracy*. A high degree of accuracy and practicality is required in the assay of precious metals, but the fire assay used is generally *applicable* to little else besides metals and minerals.

In clinical chemistry, within-laboratory *precision* (repeatability) is critical, and often is of greater interest to clinical laboratories than absolute accuracy or agreement with the values of other laboratories (reproducibility). In drug analysis, a high degree of accuracy is required in the therapeutic *range* because the analytical values determining the identity, strength, quality, and purity of pharmaceutical preparations, as laid down in pharmacopoeial specifications, are directly related to clinical value. With polynuclear hydrocarbons, *specificity* is important, since some of these compounds are carcinogenic while others are not. In applying the famous Delaney clause of the United States Federal Food, Drug, and Cosmetic Act, all attributes of the analytical methods are secondary to the detection of extremely small concentrations (*detectability*), or to exhibiting a high degree of response for small changes in concentration (*sensitivity*).

There is a very special case involving accuracy, where the "true value" is determined by the method of analysis. Many legal specifications and standards for food and agricultural products define ill-defined components such as moisture, fat, protein, and crude fiber in terms of reference methods. Therefore, the precision of these methods becomes the limiting factor for their performance. In fact, most analyses involved in commercial transactions require primarily that the buyer and seller agree on the same value (analytically and economically), regardless of where it stands on an absolute scale.

The point of these examples is that although methods of analysis are characterized by a number of attributes—accuracy, precision, specificity, sensitivity, detectability, dependability, and practicality—no method is so flawless that all these qualities can be maximized simultaneously. For any particular analysis, the analyst must determine, on the basis of the purpose of the analysis, which attributes are essential and which may be compromised.

Unfortunately, the literature is replete with examples indicating that an individual analyst, and especially the originator of a method of analysis, is not an unbiased judge of the relative merits of the methods of analysis which he develops and uses. In our experience, the collaborative study provides impartial data on the suitability of the method. The data, in many cases, speak for themselves.

The collaborative study, or ring test or round robin test, as it is called in other organizations, provides the basic information on the performance of analytical methods. The extent of the information will depend on the number of samples provided, the number of analyses performed, and the number of laboratories participating. The data should be unbiased because the composition of the samples is known only to the administrator of the study. Some of the requirements of the study and their relationship to the characteristics and attributes of the method are as follows:

- (1) *Accuracy*. Samples must be of defined composition (by spiking, by formulation, or by analytical consensus).
- (2) *Specificity*. Samples should contain related analytes.
- (3) *Sensitivity*. Samples should differ from each other or from negative samples by a known amount.
- (4) *Applicability*. Samples should include the concentration range and matrix components of interest.
- (5) *Blanks*. Samples should include different matrices with "none" of the component of interest.
- (6) *Precision*. Instructions should request replicate analyses by the same or different analysts in the same laboratory, preferably on different days. By far a better procedure is to include "blind" (unknown to the analyst) replicate samples in the series.
- (7) *Practicality*. Instructions should request information as to

the actual and elapsed time required for the analyses; the availability of reagents, equipment, and standards; and any necessary substitutions. When practice samples are included, the number of analyses required to achieve the stated recovery and repeatability, should be reported.

## PROCEDURAL DETAILS OF COLLABORATIVE STUDY

As numerous beginners in this field have discovered, much preliminary work must be done before sending out samples:

- (1) The method must be chosen and demonstrated to apply to the matrices and concentrations of interest.
- (2) The critical variables in the method should have been determined and the need for their control emphasized [a ruggedness test (5) is useful for this purpose].
- (3) The method should be written in detail by the Associate Referee and tested by an analyst not previously connected with its development.
- (4) Unusual standards, reagents, and equipment must be available from usual commercial sources of supply, or sufficient quantities must be prepared or obtained to furnish to the participants.
- (5) The samples must be identical and homogeneous so that the analytical sample error is only a negligible fraction of the expected analytical error.
- (6) A sufficient number of samples must be prepared to cover typical matrices and the concentration range of interest (tolerance, maximum or minimum specifications, likely levels of occurrence, etc.).
- (7) Samples must be stable and capable of surviving the rigors of commercial transportation.
- (8) Reserve samples should be prepared and preserved to replace lost samples and to permit reanalysis of samples considered as outliers to attempt to discover the cause of abnormal results.
- (9) The instructions must be clear. They should be reviewed by someone not connected with the study to uncover potential misunderstandings and ambiguities.
- (10) If the analyte is subject to change (e.g., bacterial levels, nitroglycerin tablets), provision must be made for all participants to begin the analysis at the same time.
- (11) Practice samples of a known and declared composition should be furnished with instructions not to analyze the unknowns until a specified degree of recovery and repeatability (or other attribute) has been achieved.
- (12) Provision should be made when necessary for submission of standard curves, tracings of recorder charts, or photographs of thin-layer plates in order to assist in determining possible causes of error.

## OTHER TYPES OF INTERLABORATORY STUDIES

This type of collaborative study, which is designed to determine the characteristics of a method, must be carefully distinguished from other types of interlaboratory studies which by design or through ignorance provide other kinds of information. The most important types of other studies are:

- (1) Those studies which require the collaborators to investigate the variability of parts of methods or applicability to different types of samples. (An interlaboratory study is usually an inefficient way of obtaining this type of information.)
- (2) Those studies which permit an analyst to use any method he desires. Such studies invariably produce such a wide scatter of results that the data are of little value for evaluation of methods. They may be useful in selecting a method from a number of apparently equivalent methods, provided the purpose

is emphasized beforehand and the participants provide a description of the method used in order to permit a correlation of the details of the methods with apparent biases and variabilities.

(3) Those studies which are used for quality control purposes, whose participants are not permitted sufficient time to gain familiarity with the method, or who permit deviations to enter into the performance of the analyses on the grounds that the deviation is obviously an improvement which could not possibly affect the results of the analysis, or who claim to have a superior method.

With this background information, it is now appropriate to introduce the following definitions which were agreed upon as part of the guidelines for collaboration between the AOAC and the Collaborative International Pesticide Analytical Council Ltd. (CIPAC) (6).

**Collaborative study.** An analytical study involving a number of laboratories analyzing the same sample(s) by the same method(s) for the purpose of validating the performance of the method(s).

**Preliminary interlaboratory study.** An analytical study in which two or more laboratories evaluate a method to determine if it is ready for a collaborative study.

**Laboratory performance check.** The analysis of very carefully prepared and homogeneous samples, normally of known active ingredient content, to establish or verify the performance of a laboratory or analyst.

### SUMMARY

The collaborative study is an experiment designed to evaluate the performance of a method of analysis through the analysis of a number of identical samples by a number of different

laboratories. With proper design, it provides an unbiased evaluation of the performance of a method in the hands of those analysts who will use it. A collaborative study must be distinguished from those studies designed to choose a method or to determine laboratory or analyst performance.

# Definitions of Terms and Explanatory Notes

## Reagents

(1) Term "H<sub>2</sub>O" means distilled water, except where otherwise specified, and except where the water does not mix with the detn, as in "H<sub>2</sub>O bath."

(2) Term "alcohol" means 95% ethanol by vol. Alcohol of strength  $x\%$  may be prepd by dilg  $x$  mL 95% alcohol to 95 mL with H<sub>2</sub>O. Absolute alcohol is 99.5% by vol. Formulae of specially denatured alcohols (SDA) used as reagents are as follows:

SDA No.	100 parts alcohol plus
1	5 wood alcohol
2-B	0.5 benzene or rubber hydrocarbon solv.
3-A	5 MeOH
12-A	5 benzene
13-A	10 ether
23-A	10 acetone
30	10 MeOH

"Reagent" alcohol is 95 parts SDA 3-A plus 5 parts isopropanol.

(3) Term "ether" means ethyl ether, peroxide-free by following test: To 420 mL ether in separator add 9.0 mL 1% NH<sub>4</sub>VO<sub>3</sub> in H<sub>2</sub>SO<sub>4</sub> (1+16). Shake 3 min and let sep. Drain lower layer into 25 mL g-s graduate, dil. to 10 mL with H<sub>2</sub>SO<sub>4</sub> (1+16), and mix. Any orange color should not exceed that produced by 0.30 mg H<sub>2</sub>O<sub>2</sub> (1 mL of soln prepd by dilg 1 mL 30% H<sub>2</sub>O<sub>2</sub> to 100 mL with H<sub>2</sub>O) and 9.0 mL 1% NH<sub>4</sub>VO<sub>3</sub> in H<sub>2</sub>SO<sub>4</sub> (1+16). Peroxides may be eliminated by passing  $\leq 700$  mL ether thru 10 cm column of Woelm basic alumina in 22 mm id tube.

(4) Reagents listed below, unless otherwise specified, have approx. strength stated and conform in purity with Recommended Specifications for Analytical Reagent Chemicals of American Chemical Society:

	Assay
Sulfuric Acid .....	95.0–98.0% H <sub>2</sub> SO <sub>4</sub>
Hydrochloric acid .....	36.5–38.0% HCl
Nitric acid .....	69.0–71.0% HNO <sub>3</sub>
Fuming nitric acid .....	$\geq 90\%$ HNO <sub>3</sub>
Acetic acid .....	$\geq 99.7\%$ HC <sub>2</sub> H <sub>3</sub> O <sub>2</sub>
Hydrobromic acid .....	47.0–49.0% HBr
Ammonium hydroxide .....	28–30% NH <sub>3</sub>
Phosphoric acid .....	$\geq 85\%$ H <sub>3</sub> PO <sub>4</sub>

Where no indication of diin is given, reagent is of concn given above.

(5) All other reagents and test solns, unless otherwise described in text, conform to requirements of American Chemical Society. Where such specifications have not been prepd, use highest grade reagent. When anhyd. salt is intended, it is so stated; otherwise the crystd product is meant.

(6) Unless otherwise specified, phenolphthalein (phtln) used as indicator is 1% alc. soln; Me orange is 0.1% aq. soln; Me red is 0.1% alc. soln.

(7) Directions for stdzg reagents are given in Chapter 50.

(8) Unusual reagents not mentioned in reagent sections or cross referenced, other than common reagents normally found in laboratory, are italicized first time they occur in method.

(9) Com. prepd reagent solns must be checked for applicability to specific method. They may contain undeclared buffers, preservatives, chelating agents, etc.

(10) In expressions (1+2), (5+4), etc., used in connection with name of reagent, first numeral indicates vol. reagent used, and second numeral indicates vol. H<sub>2</sub>O. For example, HCl (1+2) means reagent prepd by mixing 1 vol. HCl with 2 vols H<sub>2</sub>O. When one of reagents is solid, expression means parts by wt, first numeral representing solid reagent and second numeral H<sub>2</sub>O. Solns for which the solv. is not specified are aq. solns.

(11) In making up solns of definite percentage, it is understood that  $x$  g substance is dissolved in H<sub>2</sub>O and dild to 100 mL. Altho not theoretically correct, this convention will not result in any appreciable error in any of methods given in this book.

(12) Chromic acid cleaning soln is prepd by (1) adding 1 L H<sub>2</sub>SO<sub>4</sub> to ca 35 mL satd aq. Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> soln; or (2) adding 2220 mL (9 lb) H<sub>2</sub>SO<sub>4</sub> to ca 25 mL satd aq. CrO<sub>3</sub> soln (170 g/100 mL). Reagents may be tech. grade. Use only after first cleaning by other means (e.g., detergent) and draining. Mixt. is expensive and hazardous. Use repeatedly until it is dild or has a greenish tinge. Discard carefully with copious amts of H<sub>2</sub>O.

(13) All calcns are based on table of international atomic weights, 52.001.

## Apparatus

(14) Burets, vol. flasks, and pipets conform to following Federal specifications (available from General Services Admin., Specification Activity 3F1, Washington Navy Yard, Bldg. 197, Washington, DC 20407):

Buret	NNN-B-00789a	May 19, 1965
Flask, vol.	NNN-F-00289d	Feb 7, 1977
Pipet, vol.	NNN-P-395c	March 13, 1970
Pipet, measuring	NNN-P-350c	July 16, 1973

See also NBS Circular 602, "Testing of Glass Volumetric Apparatus" (available as Com 73-10504 from NTIS, Springfield, VA 22151).

(15) Standard taper (T) glass joints may be used instead of stoppers where the latter are specified or implied for connecting glass app.

(16) Sieve designations, unless otherwise specified, are those described in Federal Specification RR-S-366e, Nov 9, 1973 (available from General Services Admin.). Designation "100-mesh" (or other number) powder (material, etc.) means material ground to pass thru std sieve No. 100 (or other number). Corresponding international std and US std sieves are given in Table 1.

(17) Term "paper" means filter paper, unless otherwise specified.

(18) Term "high-speed blender" designates mixer with 4 canted, sharp-edge, stainless steel blades rotating at the bottom of 4-lobe jar at 10,000–12,000 rpm, or with equiv. shearing action. Suspended solids are reduced to fine pulp by action of blades and by lobular container, which swirls suspended solids into blades. Waring Blendor, or equiv., meets these requirements.

(19) "Flat-end rod" is glass rod with one end flattened by heating to softening in flame and pressing vertically on flat surface to form circular disk with flat bottom at end.

(20) Designation and pore diam. range of fritted glassware are: extra coarse, 170–220  $\mu$ m; coarse, 40–60; medium, 10–15; fine, 4–5.5; Jena designations and pore diam. are: 1, 110  $\mu$ m; 2, 45; 3, 25; 4, 8.

(21) Unless otherwise indicated, temps are expressed as degrees Centigrade.

**Table 1. Nominal Dimensions of Standard Test Sieves (U.S.A. Standard Series)**

Sieve Designation		Nominal Sieve Opening, inches	Nominal Wire Diameter, mm
International Standard <sup>a</sup> (ISO)	U.S.A. Standard		
12.5 mm <sup>b</sup>	1/2 in. <sup>b</sup>	0.500	2.67
11.2 mm	7/16 in.	0.438	2.45
9.5 mm	3/8 in.	0.375	2.27
8.0 mm	5/16 in.	0.312	2.07
6.7 mm	0.265 in.	0.265	1.87
6.3 mm <sup>b</sup>	1/4 in. <sup>b</sup>	0.250	1.82
5.6 mm	No. 3 1/2	0.223	1.68
4.75 mm	No. 4	0.187	1.54

<sup>a</sup> These standard designations correspond to the values for test sieve apertures recommended by the International Organization for Standardization, Geneva, Switzerland.

<sup>b</sup> These sieves are not in the standard series but they have been included because they are in common usage.

<sup>c</sup> 1000 μm = 1 mm.

### Standard Operations

(22) Operations specified as "wash (rinse, ext. etc.) with two (three, four, etc.) 10 mL (or other vol.) portions H<sub>2</sub>O (or other solv.)" mean that the operation is to be performed with indicated vol. of solv. and repeated with same vol. of solv. until number of portions required have been used.

(23) Definitions of terms used in methods involving spectrophotometry are those given in JAOAC 37, 54(1954). Most important principles and definitions are:

(a) More accurate instrument may be substituted for less accurate instrument (e.g., spectrophtr may replace colorimeter) where latter is specified in method. Wavelength specified in method is understood to be that of max. absorbance (*A*), unless no peak is present.

(b) *Absorbance(s)* (*A*).—Neg. logarithm to base 10 of ratio of transmittance (*T*) of sample to that of ref. or std material. Other

names that have been used for quantity represented by this term are optical density, extinction, and absorbancy.

(c) *Absorptivity(ies)* (*a*).—Absorbance per unit concn and cell length.  $a = A/bc$ , where *b* is in cm and *c* is in g/L, or  $a = (A/bc) \times 1000$ , if *c* is in mg/L. Other names that have been used for this or related quantities are extinction coefficient, specific absorption, absorbance index, and  $E_{1\%}^{1\text{cm}}$ .

(d) *Transmittance(s)* (*T*).—Ratio of radiant power transmitted by sample to radiant power incident on sample, when both are measured at same spectral position and with same slit width. Beam is understood to be parallel radiation and incident at right angles to plane parallel surface of sample. If sample is soln, solute transmittance is quantity usually desired and is detd directly as ratio of transmittance of soln in cell to transmittance of solv. in an equal cell. Other names that have been used for this quantity are transmittancy and transmission.

(e) *Standardization*.—Spectrophtr may be checked for accuracy of wavelength scale by ref. to Hg lines: 239.95, 248.3, 253.65, 265.3, 280.4, 302.25, 313.16, 334.15, 365.43, 404.66, 435.83, 546.07, 578.0, and 1014.0 nm. To check consistency of absorbance scale, prep. soln of 0.0400 g K<sub>2</sub>CrO<sub>4</sub>/L 0.05*N* KOH and det. absorbance at following wavelengths in 1 cm cell: 230 nm, 0.171; 275, 0.757; 313.2, 0.043; 375, 0.991; 400, 0.396. See "Standards for Checking the Calibration of Spectrophotometers," Letter Circular LC-1017, reissued Jan 1967, NBS.

(24) *Least square treatment of data and calculation of regression lines*.—This technic finds the best fitting straight line for set of data such as std curve. It calcs that straight line whose sum of squares of vertical deviations (usually *A*) of observations from the line is smaller than corresponding sum of squares of deviations from any other line. Equation of straight line is:

$$Y = a + bX,$$

where *a* is intercept at *Y* axis (*X* = 0), and *b* is slope of line.

Least square estimates of constants are:

$$b = \frac{\sum(X_i Y_i) - [(\sum X_i \sum Y_i)/n]}{\sum X_i^2 - (\sum X_i)^2/n}$$

$$a = \bar{Y} - b\bar{X},$$

where  $\Sigma$  = "sum of" the *n* individual values of indicated operation, and  $\bar{X}$  and  $\bar{Y}$  are the averages of the *X* and *Y* points.

*Example:* To find "best" straight line relating *A* (*Y*) to concn (*X*):

Observation No. ( <i>i</i> )	Concn <i>X<sub>i</sub></i>	Absorbance <i>Y<sub>i</sub></i>	<i>X<sub>i</sub><sup>2</sup></i>	<i>X<sub>i</sub>Y<sub>i</sub></i>
1	80	1.270	6400	101.6
2	60	1.000	3600	60.0
3	40	0.700	1600	28.0
4	30	0.550	900	16.5
5	20	0.250	400	5.0
6	10	0.100	100	1.0
7	0	0.050	0	0.0

Totals:  
*n* = 7       $\Sigma X_i = 240$        $\Sigma Y_i = 3.92$        $\Sigma X_i^2 = 13000$        $\Sigma(X_i Y_i) = 212.1$

$$\bar{X} = \Sigma X_i/n = 240/7 = 34.29$$

$$\bar{Y} = \Sigma Y_i/n = 3.92/7 = 0.56$$

$$b = \frac{212.1 - (240)(3.92)/7}{13000 - (240)^2/7} = \frac{77.7}{4771} = 0.0163$$

$$a = 0.56 - 0.0163(34.29) = 0.001$$

Best equation is then:

$$Y = 0.00 + 0.0163X$$

If for sample, *A* = 0.82, corresponding concn (*X*) would be:

$$X = (Y - 0.00)/0.0163 = 0.82/0.0163 = 50.3.$$

Many scientific and statistical calculators are preprogrammed to perform this calcn.

(25) Common safety precautions are given in Chapter 51.

#### **Editorial Conventions**

(26) For sake of simplicity, abbreviations Cl and I instead of Cl<sub>2</sub> and I<sub>2</sub> are used for chlorine and iodine. Similar abbreviations have been used in other cases (O, N, H). The same abbreviation may also be used for the ion where no ambiguity will result.

(27) Reagents and app. referenced with only a letter, e.g., (c), will be found in the reagent or apparatus section of that method.

(28) To conserve space, most of the articles and some prepositions have been eliminated.

(29) Names and addresses of manufacturers and suppliers, and trade names of frequently mentioned materials, are furnished below solely as a matter of identification and convenience, without implication of approval, endorsement, or certification. The same products available from other suppliers or other brands from other sources may serve equally well if proper tests indicate their use is satisfactory. These firms when mentioned in a method are given by name only (without addresses).

 thetics Div., 12 E Ave, Tallmadge, OH 44278

(30) The following abbreviations, many of which conform with those of *Chemical Abstracts*, are used. In general, principle governing use of periods after abbreviations is that period is used where final letter of abbreviation is not the same as final letter of word it represents. Periods are not used with units, except inch(es) and gallon(s).

Abbreviation	Word
a	absorptivity(ies)
A	absorbance(s) thruout (not restricted to for- mulas); not absorption. A' is used for std; A <sub>0</sub> for blank; 3 digit subscript numerals usually denote wavelengths in nm
AA	atomic absorption
Ac	CH <sub>3</sub> CO- (acetyl, not acetate)
ACS	American Chemical Society
addn	addition
addnl	additional
alc.	alcoholic (not alcohol)
alk.	alkaline (not alkali)
alky	alkalinity
amp	ampere(s)
amt	amount
anal.	analytical(ly)
anhyd.	anhydrous
AOCS	American Oil Chemists' Society
app.	apparatus
approx.	approximate(ly)
aq.	aqueous
ASTM	American Society for Testing and Materials
atm.	atmosphere, atmospheric
av.	average (except as verb)
Bé.	degree Baumé
bp	boiling point
Bu	butyl
C	degrees Celsius (Centigrade)
ca	about, approximately
calc.	calculate
calcd	calculated
calcg	calculating
calcn	calculation
Cat. No.	Catalog Number
centrf.	centrifuge
centrfd	centrifuged
centrfg	centrifuging
Chap.	Chapter
chem.	chemical(ly)
chromatgc	chromatographic
chromatgd	chromatographed
chromatgy	chromatography
Ci	curie(s)
CI	Color Index
CIPAC	Collaborative International Pesticides Ana- lytical Council
cm	centimeter(s)
compd	compound
com.	commercial(ly)
conc.	concentrate (as verb or noun)
concd	concentrated
concg	concentrating
concn	concentration
const	constant
contg	containing
cP	centipoise
cpm	counts per minute
cryst.	crystalline (not crystallize)
crystd	crystallized
crystg	crystallizing
crystn	crystallization
cu in.	cubic inch(es)
dc	direct current
det.	determine
detd	determined

Abbreviation	Word	Abbreviation	Word
detg	determining	m	molal
detn	determination	M	molar (as applied to concn), not molal
diam.	diameter	ma	milliampere (cf amp)
diat. earth	diatomaceous earth	mag.	magnetic(ally)
dil.	dilute	max.	maximum
dild	diluted	mech.	mechanical(ly)
dilg	diluting	Me	methyl
diln	dilution	MeOH	methyl alcohol
distd	distilled	mg	milligram(s)
distg	distilling	min	minute(s)
distn	distillation	min.	minimum
DMF	<i>N,N</i> -dimethylformamide	mixt.	mixture
DMSO	dimethyl sulfoxide	mL	milliliter(s)
EDTA	ethylenedinitrilotetraacetic acid (or -tetraacetate)	mm	millimeter(s)
<i>e.g.</i>	for example	mp	melting point
elec.	electric(al)	mμ	millimicron (10 <sup>-6</sup> mm); use nanometer (nm) (10 <sup>-9</sup> m)
equiv.	equivalent	mv	millivolt
est.	estimate	MW	molecular weight
estd	estimated	N	normal (as applied to concn); in equations, normality of titrating reagent
estg	estimating	N	Newton (10 <sup>5</sup> dynes)
estn	estimation	<i>n</i>	refractive index
Et	ethyl	NBS	National Bureau of Standards
EtOH	ethanol (the chemical entity C <sub>2</sub> H <sub>5</sub> OH)	NCA	National Canners Association (now National Food Processors Association)
evap.	evaporate	neg.	negative
evapd	evaporated	neut.	neutral
evapg	evaporating	neutze	neutralize
evapn	evaporation	neutzd	neutralized
ext	extract	neutzg	neutralizing
extd	extracted	neutzn	neutralization
extg	extracting	NF	National Formulary
extn	extraction	ng	nanogram (10 <sup>-9</sup> g)
F	degrees Fahrenheit (°C = (5/9) × (°F - 32))	nm	nanometer (10 <sup>-9</sup> m); formerly mμ
FAO	Food and Agriculture Organization	No.	number
Fig.	Figure (illustration)	-OAc	acetate (cf Ac)
fl oz	fluid ounce(s) (29.57 mL)	-OCN	cyanate
fp	freezing point	od	outer diameter (or dimension)

(31) ★ This symbol indicates a method which is in or is being considered for "surplus" status. Such methods are satisfactory methods, having been subjected to collaborative studies and review. They are thought not to be in current use for various reasons: The purpose for which they were developed no longer exists; the product for which they were developed no longer is marketed; they have been replaced by other methods; etc. These methods retain their official status but are carried in this or next edition only by ref. Any laboratory who uses these methods and wishes the text retained or reprinted in next edition must so notify the AOAC.

(32) Nos. appearing in titles of methods in bold face refer to the Selected References at the end of the Chap. These refs often contain the performance data supporting the adoption of the method.

# 1. Agricultural Liming Materials

## 1.001 Sampling (1)—Procedure

(Caution: See 51.036.)

Take sample representative of lot or shipment. Avoid disproportionate amt of surface or any modified or damaged zone.

(a) *Burnt or lump lime, in bulk.*—Collect composite sample of  $\geq 10$  shovelfuls/car, with proportionate amts from smaller lots, taking each shovelful from different part of lot or shipment. Immediately crush to pass 5 cm (2") diam. circular opening, mix thoroly and rapidly, reduce composite to ca 2 kg (5 lb) sample by riffing or quartering, and place in labeled, dry, air-tight container.

(b) *Hydrated lime and ground burnt lime, in bags.*—Select 10 bags from different parts of each lot or shipment of  $\leq 20$  tons and 1 addnl bag for each addnl 5 tons. Use sampling tube to withdraw top to bottom core from each bag selected. Combine cores, mix thoroly and rapidly, reduce composite to ca 1 kg (2 lb) by riffing or quartering, and place in dry, air-tight container.

(c) *Ground limestone and ground marl, in bags.*—Proceed as in (b).

(d) *Ground limestone, ground burnt lime, ground marl, and slag, in bulk.*—Use slotted sampling tube to withdraw samples to full sampler depth from 10 points in lot or shipment. Proceed as in (b), beginning "Combine cores, . . ."

## 1.002 Mechanical Analysis (2)—Procedure

(Caution: See 51.036.)

If entire sample is not to be dried, obtain lesser portions by riffing or quartering. Dry at  $110^\circ$  to const wt and cool to room temp.

Obtain 90–150 g dry sample by riffing or quartering. Break any agglomerates formed during drying by rolling dry sample with hard rubber roller on hard rubber mat, wet sieving as in 2.011(a), or by equally effective means that does not result in crushing the limestone. (If wet sieving is used to break agglomerates, do wet sieving on sieve having smallest opening to be used in final testing. After drying, transfer to sieves to be used in final testing. If only 1 sieve is to be used, do not transfer.) Quant. transfer weighed sample to 8" diam. std sieve or set of sieves (e.g., Nos. 10, 20, 40, 60, 80, and 100 or other appropriate combination).

Sieve by lateral and vertical motion accompanied by jarring action. Continue  $\geq 5$  min or until addnl 3 min of sieving time fails to change results of any sieve fraction by 0.5% of total sample wt. Do not overload any sieve when assaying closely sized materials.

Det. wt of each sieve fraction and report as % of total sample wt.

## 1.003 Preparation of Sample (1)—Procedure

Reduce dried sample, 1.002, to amt sufficient for analysis and grind  $\geq 225$  g (0.5 lb) reduced sample in mortar, ball mill, or other mech. app. to pass No. 60 sieve. Mix thoroly, and store in air-tight container.

### Neutralizing Value—Official Final Action

(Uncorrected for sulfide content)

## 1.004

### Reagents

(a) *Sodium hydroxide std soln.*—0.25*N*. Prep. and stdze as in 50.032–50.036.

(b) *Hydrochloric acid std soln.*—0.5*N*. Stdze against (a), using phthln.

## 1.005 Indicator Titration Method

Place 0.5 g burnt or hydrated lime (1 g ground limestone or ground marl), prepd as in 1.003, in 250 mL erlenmeyer; add 50 mL HCl std soln and boil *gently* 5 min. Cool, and titr. excess acid with NaOH std soln, using phthln. For burnt and hydrated lime, report as % CaO; for limestone and marl, report as % CaCO<sub>3</sub> equivalence.

$$\% \text{ CaCO}_3 \text{ equivalence of sample} = 2.5 \times (\text{mL HCl} - \text{mL NaOH}/2).$$

$$\% \text{ CaO equivalence} = 2.8 \times (\text{mL HCl} - \text{mL NaOH}/2).$$

## 1.006 Potentiometric Titration Method (3)

(Applicable to liming materials contg large amt of Fe<sup>+2</sup> or coloring matter, but not to silicate materials)

Proceed as in 1.005 thru "Cool, . . ." Transfer to 250 mL beaker and insert glass and calomel electrodes of pH meter, buret contg 0.25*N* NaOH, and mech. stirrer. Stir at moderate speed to avoid splash. Deliver NaOH rapidly to pH 5, then dropwise until soln attains pH 7 and remains const 1 min while stirring. (If end point is passed, add, from 1 mL Mohr pipet, just enough 0.5*N* HCl to bring pH to  $<7$ , and back-titr. slowly to pH 7.) Add mL of excess acid, if used, to initial 50 mL in calcg. Report as % CaCO<sub>3</sub> or CaO equivalence as in 1.005.

## 1.007 Approximate Proportions of Calcium and Magnesium in Magnesic Limestone

Slightly acidify titrd soln, 1.005 or 1.006, transfer to 250 mL vol. flask, and dil. to vol. Det. Ca in 50 mL aliquot as in 7.096, beginning ". . . dil. to ca 100 mL . . ." Subtract its CaCO<sub>3</sub> equivalence from total CaCO<sub>3</sub> equivalence, 1.005 or 1.006, and assign difference as CaCO<sub>3</sub> equivalence of the Mg content of the limestone.

### Caustic Value (4)—Official Final Action

## 1.008

### Apparatus (Figure 1:01)

Use 500 mL Pyrex erlenmeyer, *A*, and fritted glass filter (Corning Glass Works No. 39535, 30F), *F*. Connect filter to siphon tube *B* with thick-wall rubber tubing. Use receiving flasks *M* and *N* calibrated to deliver 50 and 100 mL, resp. *S* is suction flask.

## 1.009

### Determination

Transfer portion of sample, 1.003, to weighing bottle and det. wt bottle and contents in atm. of min. moisture and CO<sub>2</sub> content. With polished, narrow-point spatula calibrated to hold ca 1.5 g, withdraw sample to be used and det. exact wt by difference. Insert sample directly into dry flask, *A*, fitted with tight rubber stopper.

Prep. *sucrose soln immediately before use* by placing 25 g granulated sucrose in measuring flask calibrated to deliver 500 mL. Dissolve sucrose with cold CO<sub>2</sub>-free H<sub>2</sub>O and dil. to vol. Holding both erlenmeyer contg sample and flask contg sucrose soln in slightly inclined position, insert neck of sucrose soln flask short distance into erlenmeyer, and carefully transfer sucrose soln with synchronized rotary motion of both flasks to prevent granulation of lime. Stopper erlenmeyer securely, agitate, and

add, if desired, some clean dry beads. Completely dissolve uncoated caustic lime by six 1 min agitations at 2 or 3 min intervals. Invert flask to trap any solid particles between stopper and neck and crush by carefully twisting stopper. Let stand 15 min and filter as follows:

Connect filter cone *F* with siphon *B* and close stopcock *D*. Connect receiving flasks, apply suction, and quickly connect erlenmeyer *A* contg lime soln with stopper *E*. Open stopcock *C* and filter 25–50 mL soln. Close *C* and open *D* to release suction. Remove *M* and replace with similar dry flask. Close *D*, open *C*, and continue filtration until both *M* and *N* are filled at least to marks. To disconnect system, close stopcock *C*, and gently press down outlet of flask *M* and then outlet of flask *N*, to remove any excess liq. above marks. Let intermediate connection empty, open stopcock *D*, and remove *M* and *N*. Titr. first 50 mL, or pilot aliquot, of filtered soln with 0.5*N* HCl, using phthln. To covered 200 mL beaker add twice vol. 0.5*N* acid required for this titrn, add second (100 mL) aliquot of filtered soln to this acid and phthln, and complete titrn.

Calc. caustic value of sample:  $X = 7V/W$ ,

where  $X$  = % active CaO;  $V$  = mL 0.5*N* acid used/100 mL lime soln;  $W$  = g sample.

#### Carbon Dioxide (5)—Official Final Action

##### 1.010

##### Apparatus and Reagents

*Knorr alkalimeter with CO<sub>2</sub> absorption train.*—Fill guard tube of alkalimeter with Ascarite. Connect upper end of condenser to absorption train consisting of 5 or 6 U-shape, g-s drying tubes (or equiv.) joined in series. Fill first tube with H<sub>2</sub>SO<sub>4</sub> and second with Ag<sub>2</sub>SO<sub>4</sub>-H<sub>2</sub>SO<sub>4</sub> soln (10 g Ag<sub>2</sub>SO<sub>4</sub> in 100 mL H<sub>2</sub>SO<sub>4</sub>) to remove acidic gases other than CO<sub>2</sub>. Fill third tube with Mg(ClO<sub>4</sub>)<sub>2</sub> to absorb H<sub>2</sub>O. Fill inlet  $\frac{2}{3}$  of fourth and succeeding tubes with Ascarite to absorb CO<sub>2</sub>, and outlet  $\frac{1}{3}$  of each tube with Mg(ClO<sub>4</sub>)<sub>2</sub>. Connect last tube in train with aspirating bottle or suction source.

Condition app. daily before use, and also when freshly filled tube is placed in train, by aspirating air at rate of 2–3 bubbles/sec thru dry alkalimeter assembly and absorption train until CO<sub>2</sub> absorption tubes attain const wt (usually 20–30 min). Tare against similarly packed tubes. Use std procedure for wiping tubes with dry, lint-free cloth before each weighing.

##### 1.011

##### Determination

Transfer 3 g burnt or hydrated lime or 0.5–1.0 g limestone or marl, prepd as in 1.003, to dry alkalimeter flask. Momentarily open stopcocks of first 2 CO<sub>2</sub> absorption tubes to air to equalize pressure, weigh tubes sep., and place in position in train. With assembled alkalimeter connected to absorption train, adjust rate of aspiration of air thru system to ca 2 bubbles/sec. Close funnel stopcock, remove alkalimeter guard tube, fill funnel with 50 mL HCl (1+4), and replace guard tube. Open funnel stopcock and let acid run slowly into flask, taking care that evolution of gas is so gradual as not to materially increase flow thru tubes. After all acid is added, agitate alkalimeter assembly to ensure complete dispersion of sample in acid soln. Continue aspiration, gradually heat contents of flask to bp, and boil 2–3 min after H<sub>2</sub>O begins to condense. Discontinue heating, and continue aspiration 15–20 min or until app. cools. Remove, equalize internal and external pressure, and reweigh absorption tubes.

Increase in wt = wt CO<sub>2</sub>. (Material increase in wt of second tube usually indicates exhaustion of first tube, but may result from too rapid evolution of CO<sub>2</sub> in relation to aspiration rate.) Report % CaCO<sub>3</sub>.

#### CALCIUM SILICATE SLAGS

##### 1.012 Neutralizing Value (6)—Official Final Action

(Uncorrected for sulfide content)

(a) *Blast furnace slag.*—Transfer 0.5 g sample, ground to pass No. 80 sieve, to 250 mL erlenmeyer. Wash down with small

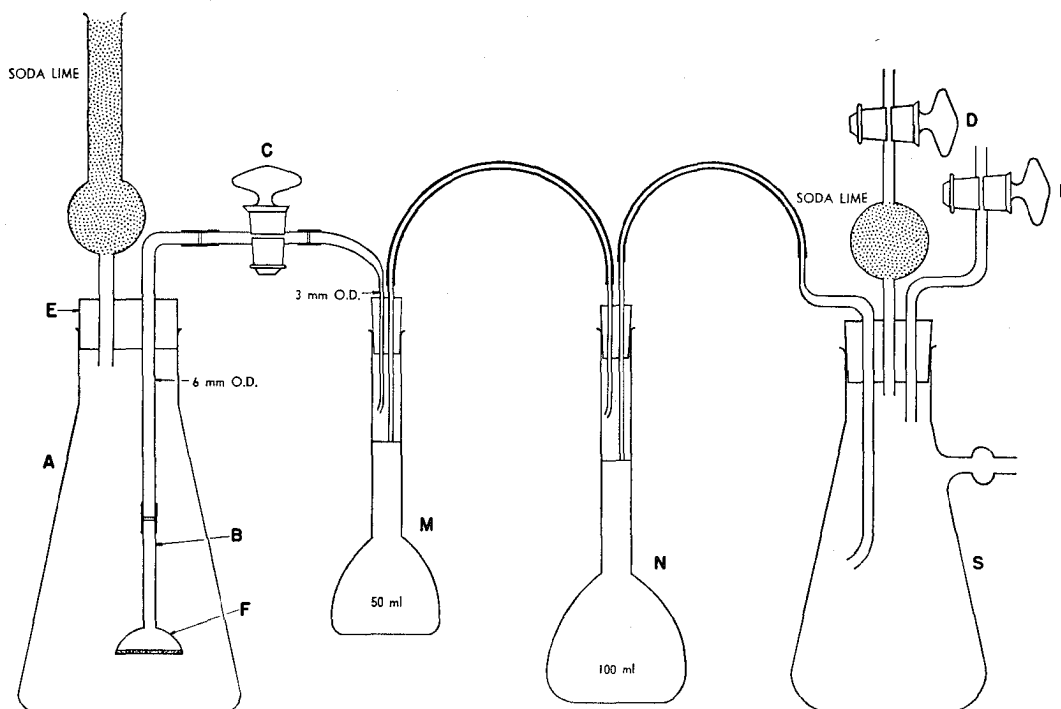

FIG. 1:01—Apparatus for automatic filtration and measurement of lime solutions

portions  $\text{H}_2\text{O}$  and add 35 mL 0.5*N* HCl while swirling. Heat to gentle boil over burner, *agitating suspension continuously* until bulk of sample dissolves. Boil 5 min and cool to room temp.; then dil. with  $\text{CO}_2$ -free  $\text{H}_2\text{O}$  to ca 150 mL and add 1 mL 30%  $\text{H}_2\text{O}_2$  and 5 drops bromocresol green, **2.144(c)**. Back-titr. with 0.5*N* NaOH, adding first 15 mL rapidly and titrg dropwise thereafter, vigorously agitating contents of stoppered flask after each addn, until indicator tint matches or slightly exceeds that of pH 5.2 phthalate buffer soln, **50.010**, of like vol. and indicator concn, after 2–3 sec agitation.

(b) *Rock phosphate reduction furnace slag*.—Transfer 0.5 g sample to 250 mL beaker. Wash down with small portions  $\text{H}_2\text{O}$  and add, stirring continuously, 50 mL HOAc (1+4). Heat to bp and boil 5 min, stirring frequently. Evap. to dryness on steam bath. Add 20 mL of the HOAc, dil. to 150 mL, and heat to bp; add  $\text{NH}_4\text{OH}$  (1+1) to distinct yellow of Me red. Digest ca 10 min on hot plate. Filter by gravity thru 9 cm paper, catching filtrate in 100 × 50 mm lipped Pyrex crystg dish; wash beaker 3 times and paper 5 addnl times with *neut.* 0.5*N*  $\text{NH}_4\text{OAc}$ . Evap. filtrate on hot plate. Adjust heat so bubbles breaking thru viscous surface film are released gently to avoid spattering. (To expedite dehydration, repeat treatments with 25 mL hot  $\text{H}_2\text{O}$  and evapn 2 or 3 times.) Continue heating residue on hot plate until no HOAc odor remains. Heat addnl 10 min at full heat of hot plate; then ignite 10 min at 550°. Cool, wet residue with 15 mL  $\text{H}_2\text{O}$ , place watch glass over dish, and add 25 mL 0.5*N* HCl thru lip of dish. Heat 5 min over burner at gentle simmer. Rinse watch glass, filter suspended matter on 9 cm paper, catching filtrate in 250 mL erlenmeyer, and wash dish and filter 3 times with hot  $\text{H}_2\text{O}$ . Titr. excess acid with 0.5*N* NaOH to distinct yellow of Me red.

Net acid used × 5 = neutzg value of slag in terms of %  $\text{CaCO}_3$  equivalence.

#### Sulfide Sulfur (7)—Official Final Action

(Note:  $\text{CdSO}_4$  is toxic: see also **51.084**.)

#### 1.013

#### Reagents

(a) *Zinc dust*.—Low in Pb.

(b) *Absorbent soln*.—Dissolve 20 g  $\text{CdSO}_4 \cdot 2\frac{1}{2}\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 1 L. Adjust to pH 5.6 potentiometrically or colorimetrically. If colorimetrically, match sep. 50 mL aliquot to buffer of same pH, **50.010**.

(c) *Sodium hydroxide std soln*.—0.1*N*. Prep. and stdze as in **50.032–50.036**.

(d) *Std acid*.—0.1*N* HCl. Stdze against std alkali, (c), using Me red.

(e) *Methyl red indicator*.—Dissolve 0.2 g Me red in 100 mL alcohol.

#### 1.014

#### Apparatus

Fit 250 mL erlenmeyer with 2-hole No. 5.5 stopper. Insert thru stopper 60 mL separator with stem drawn out to 2 mm and bent upward at tip, adjusting separator so stem is 6 mm from bottom of flask. Also insert thru stopper 6 mm glass outlet tube. Connect with amber rubber tubing to inlet of 25 × 150 mm tube half filled with  $\text{H}_2\text{O}$  and heated to near bp before and during detn. Connect in series 2 addnl tubes of same size, each contg 25 mL absorbent soln and held in 600 mL beaker filled with cold  $\text{H}_2\text{O}$ .

#### 1.015

#### Determination

Fill absorbent tubes with absorbent soln and heat  $\text{H}_2\text{O}$  tube to gentle boiling. Weigh 1 g slag, ground to pass No. 80 sieve, into evolution flask, add 1 g Zn dust, and wash down sides with 5–10 mL  $\text{H}_2\text{O}$ ; mix with flat-end rod and connect flask to app.

Add 50 mL HCl (1+4) to separator and let acid flow into reaction flask while swirling contents. If necessary, apply pressure to transfer acid and close stopcock while a little of the acid is still above it. Heat to bp; then regulate to maintain active but not too vigorous boiling for 10 min. Swirl flask frequently after adding acid and for first 5 min of boiling. To disconnect, hold inlet in first absorbent tube firmly with one hand and quickly pull off rubber tubing with other hand without pinching.

Filter CdS suspension by gravity thru 9 cm paper into 250 mL erlenmeyer and wash with  $\text{H}_2\text{O}$  to vol. of 100 mL. Add 4 drops Me red indicator and agitate vigorously while titrg slowly with 0.1*N* NaOH to exact tint of *ref. soln* (50 mL absorbent soln dild to 100 mL, with identical indicator concn, in 250 mL erlenmeyer). If end point is passed so that  $\text{Cd}(\text{OH})_2$  ppts, add 1–2 mL 0.1*N* HCl, let stand until ppt disappears, and complete titrn dropwise, agitating vigorously.

%  $\text{CaCO}_3$  equivalence of sulfide S in sample = net mL 0.1*N* NaOH/2

g Sulfide S/detn = mL 0.1*N* NaOH × 0.0016

% Sulfide S = g sulfide S × 100

### ELEMENTAL ANALYSIS

#### Gravimetric Methods

#### 1.016 Preparation of Sample Solution by Acid Digestion (8)—Official Final Action

(Caution: See **51.019**, **51.026**, and **51.028**.)

Prep. samples as in **1.003**, preferably in agate mortar. Grind silicates to pass No. 100 sieve, and dry all samples at 105°.

Weigh 2 g limestone or 0.5 g silicate. If sample contains org. matter, transfer to Pt crucible and place in cold furnace. Raise temp. gradually to 1000° and hold 15 min. Transfer sample to 400 mL beaker and, if ignited, moisten cautiously with  $\text{H}_2\text{O}$ . Add 10 mL  $\text{HNO}_3$  and evap. on hot plate at low heat until mixt. becomes pasty. Cool, and add 10 mL  $\text{H}_2\text{O}$  and 20 mL 60%  $\text{HClO}_4$ . Boil to heavy fumes of  $\text{HClO}_4$ , cover, and fume slowly until soln is colorless or slightly yellow (5–10 min). Do not evap. to dryness. Cool to <100° and add 50 mL  $\text{H}_2\text{O}$ . Filter thru Whatman 41H or finer paper into 250 mL vol. flask. *Wash thoroly with hot  $\text{H}_2\text{O}$  to remove all traces of  $\text{HClO}_4$* . Reserve filtrate and washings for prepn of Sample Solns X and Y, **1.017(a)** and **(b)**.

#### 1.017 Silica (8)—Official Final Action

(See also **1.041–1.043**.)

(Caution: See **51.025** and **51.028**.)

Transfer paper with  $\text{SiO}_2$  to uncovered Pt crucible and heat gently with low flame until paper chars without flame. Partially cover crucible and cautiously burn C. Finally cover completely and heat with blast lamp or in furnace at 1150–1200°. Cool in desiccator and weigh. Repeat to const wt (W). Treat with ca 1 mL  $\text{H}_2\text{O}$ , 2 drops  $\text{H}_2\text{SO}_4$  (1+1), and 10 mL HF. Cautiously evap. to dryness in hood. Heat 2 min at 1050–1100°, cool in desiccator, and weigh (B).

$W - B = \text{g SiO}_2 \text{ in sample.}$

$\text{g SiO}_2 \times 0.4674 = \text{g Si.}$

(a) *Sample Soln X*.—(0.008 g limestone or 0.002 g silicate/mL.) Fuse residue from Si detn with 0.5 g  $\text{Na}_2\text{CO}_3$  by heating covered crucible 10 min over Meker burner. Cool, fill crucible  $\frac{2}{3}$  full with  $\text{H}_2\text{O}$ , and add 2 mL 60%  $\text{HClO}_4$  dropwise, with stirring. Warm if necessary to dissolve melt. Add to filtrate and washings reserved for prepn of Sample Soln X in **1.016**. Dil. to 250 mL with  $\text{H}_2\text{O}$ .

(b) *Sample Soln Y*.—(0.00016 g limestone or 0.00004 g silicate/mL.) Dil. 10 mL Sample Soln X to 500 mL with  $\text{H}_2\text{O}$ .

### 1.018 Oxides of Iron, Aluminum, Phosphorus, and Titanium (9)—Official Final Action

(Alternatively, Fe, Al, Mn, P, and Ti may be detd colorimetrically as in 1.025–1.040.)

To 125 mL aliquot *Soln X* from 1.017(a), add 10 mL HCl and few drops Me red indicator; heat to gentle boil and add  $\text{NH}_4\text{OH}$  (1+1) until ppt forms and indicator just changes to distinct yellow. Boil  $\leq 2$  min and filter rapidly. Wash ppt 6–8 times with hot 2%  $\text{NH}_4\text{NO}_3$  soln. Return ppt and filter to original beaker, add 10 mL HCl, and macerate filter with policeman. Dil. with  $\text{H}_2\text{O}$ , heat to dissolve ppt, dil. to ca 200 mL, and reppt as above. Wash thoroly with the hot  $\text{NH}_4\text{NO}_3$  soln until Cl-free. Combine first and second filtrates and save for Ca and Mg detns.

Place ppt in Pt crucible and dry. Ignite gently to oxidize C, heat to bright red ca 10 min, cool in desiccator, and weigh in covered crucible as  $\text{Fe}_2\text{O}_3 + \text{Al}_2\text{O}_3 + \text{P}_2\text{O}_5 + \text{TiO}_2$ .

### 1.019 Calcium (9)—Official Final Action

Conc. combined filtrates and washings from 1.018 to ca 50 mL; make slightly alk. with  $\text{NH}_4\text{OH}$  (1+1); while still hot, add *satd*  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  soln dropwise as long as any ppt forms, and then enough excess to convert Mg salts also to oxalate. Heat to bp, let stand  $\geq 3$  hr, decant clear soln thru filter, pour 15–20 mL hot  $\text{H}_2\text{O}$  on ppt, and again decant clear soln thru filter. Dissolve any ppt remaining on filter by washing with hot HCl (1+9) into original beaker, wash 6 times with hot  $\text{H}_2\text{O}$ , and then reppt at bp by adding  $\text{NH}_4\text{OH}$  and a little *satd*  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  soln. Let stand as before, filter thru same filter, and wash with hot  $\text{H}_2\text{O}$  until Cl-free. Reserve filtrates and washings from both pptns for detn of Mg, 1.021.

Complete detn by one of following methods and report as % CaO:

(a) Ignite ppt in crucible, either over S-free blast lamp, or in elec. furnace at  $950^\circ$ , to const wt, cool in desiccator, and weigh as CaO.

(b) Incinerate filter over low flame, mix ignited ppt with finely pulverized and dried mixt. of equal parts of  $(\text{NH}_4)_2\text{SO}_4$  and  $\text{NH}_4\text{Cl}$ , and drive off excess sulfate by carefully heating upper portion of crucible. Complete ignition, cool in desiccator, and weigh as  $\text{CaSO}_4$ .

(c) Perforate apex of cone; wash  $\text{CaC}_2\text{O}_4$  ppt into beaker used for pptn; then wash filter with hot  $\text{H}_2\text{SO}_4$  (1+4), and titr. at  $85\text{--}90^\circ$  with 0.1N  $\text{KMnO}_4$ .

### Magnesium (10)—Official Final Action

#### 1.020

#### Reagent

*Phosphate soln.*—Dissolve 100 g  $(\text{NH}_4)_2\text{HPO}_4$  in hot  $\text{H}_2\text{O}$ , dil. to 1 L, and add 5 mL  $\text{HCl}$ .

#### 1.021

#### Determination

To combined filtrates and washings, 1.019, add 2 mL 1M citric acid, 100 mL  $\text{NH}_4\text{OH}$ , and 50 mL alcohol. Then add 25 mL of the phosphate soln, with const stirring, and let stand 12–24 hr. Filter, wash twice with  $\text{NH}_4\text{OH}$  (1+9), and dissolve ppt in  $\text{HNO}_3$  (1+4), washing soln into original beaker to vol. of 100–150 mL. Add 1/10 vol.  $\text{NH}_4\text{OH}$  and 2 drops of the phosphate soln. Stir vigorously and let stand  $\geq 3$  hr. Filter thru gooch, wash with  $\text{NH}_4\text{OH}$  (1+9), moisten filter with *satd soln* of  $\text{NH}_4\text{NO}_3$  made slightly ammoniacal, ignite, and weigh as  $\text{Mg}_2\text{P}_2\text{O}_7$ . Report as % MgO. Correct wt  $\text{Mg}_2\text{P}_2\text{O}_7$  for co-pptd  $\text{Mn}_2\text{P}_2\text{O}_7$  by detg Mn as in 33.127.

### EDTA Titration Methods

### Calcium and Magnesium (11)—Official Final Action

(Not applicable to samples with high phosphate content or contg  $<2\%$  Mg)

(Caution: See 51.050.)

#### 1.022

#### Reagents

(a) *Buffer soln.*—pH 10. Dissolve 67.5 g  $\text{NH}_4\text{Cl}$  in 200 mL  $\text{H}_2\text{O}$ , add 570 mL  $\text{NH}_4\text{OH}$ , and dil. to 1 L.

(b) *Potassium hydroxide-potassium cyanide soln.*—Dissolve 280 g KOH and 66 g KCN in 1 L  $\text{H}_2\text{O}$ .

(c) *Potassium cyanide soln.*—2%. Dissolve 2 g KCN in 100 mL  $\text{H}_2\text{O}$ .

(d) *Eriochrome black T indicator soln.*—Dissolve 0.2 g indicator (Eastman Kodak P6361, or equiv.) in 50 mL MeOH contg 2 g  $\text{NH}_4\text{OH} \cdot \text{HCl}$ . Store  $\leq 1$  month.

(e) *Magnesium std solns.*—0.25 and 1.00 mg/mL. Dissolve 0.25 and 1.00 g Mg turnings in HCl (1+10) and dil. each to 1 L with double distd  $\text{H}_2\text{O}$ .

(f) *Calcium std soln.*—1 mg/mL. Dissolve 2.4973 g  $\text{CaCO}_3$ , primary std grade, previously dried 2 hr at  $285^\circ$ , in HCl (1+10). Dil. to 1 L with double distd  $\text{H}_2\text{O}$ .

(g) *Calcein indicator.*—Grind together 1 g indicator, 10 g charcoal (Norite A is satisfactory), and 100 g KCl. (Indicator is described in Anal. Chem. 28, 882 (1956), and is available from G. Frederick Smith Chemical Co. and Eastman Kodak.)

(h) *Disodium dihydrogen EDTA std solns.*—(1) 0.4%.—Dissolve 4 g  $\text{Na}_2\text{H}_2\text{EDTA}$  in 1 L  $\text{H}_2\text{O}$ . Stdze against std Ca and Mg solns. (2) 0.1%.—Prep. as in (1), using 1 g  $\text{Na}_2\text{H}_2\text{EDTA}$ , and stdze against 0.25 mg/mL Mg std soln.

#### 1.023

#### Standardization

(a) *For calcium.*—Pipet 10 mL std Ca soln into 300 mL erlenmeyer and add 10 mL  $\text{H}_2\text{O}$ . Add 10 mL KOH-KCN soln and ca 35 mg calcein indicator. Using mag. stirrer and artificial light, titr. with 0.4% EDTA std soln to disappearance of all green. Titr.  $\geq 3$  aliquots and use av. to calc. titer Ca soln = 10/mL EDTA soln.

(b) *For magnesium.*—Pipet 10 mL 0.25 and 1.00 mg/mL Mg std solns into 300 mL erlenmeyers and add 100 mL  $\text{H}_2\text{O}$ . Add 5 mL pH 10 buffer, 2 mL 2% KCN soln, and 10 drops eriochrome black T indicator. Using mag. stirrer and artificial light, titr. with 0.1 and 0.4% EDTA std solns, resp., until color changes permanently from wine red to pure blue. Titr.  $\geq 3$  aliquots and use av. to calc. titer Mg soln = 2.5/mL EDTA soln, or 10/mL EDTA soln, resp.

#### 1.024

#### Determination

Dry sample at  $110^\circ$  to const wt and cool to room temp. Grind to pass No. 60 or 80 sieve and mix thoroly. Accurately weigh ca 0.5 g into 250 mL beaker, add 20 mL HCl (1+1), and evap. to dryness on hot plate. Dissolve residue in 5 mL HCl (1+10), dil. to ca 100 mL with  $\text{H}_2\text{O}$ , and digest over low flame 1 hr. Cool, transfer to 200 mL vol. flask, dil. to vol., mix, and let settle or filter.

(a) *For calcium.*—Pipet 10 mL aliquot into 300 mL erlenmeyer and titr. as in 1.023(a), observing end point thru soln and away from light. % Ca = (Titer EDTA std soln for Ca)  $\times$  mL EDTA std soln  $\times$  2/g sample.

(b) *For magnesium.*—(For agricultural limestones contg  $>4\%$  Mg.) For Ca + Mg, pipet 10 mL aliquot into 300 mL erlenmeyer and titr. with 0.4% EDTA soln as in 1.023(b).

% Mg = (Titer EDTA std soln for Mg)  $\times$  [(mL EDTA std soln in Ca + Mg titrn) – (mL EDTA std soln in Ca titrn)]  $\times$  2/g sample.

(c) *For magnesium.*—(For agricultural limestones contg 2–4%

Mg.) Pipet 10 mL aliquot (0.5–1.0 mg Mg) into 300 mL erlenmeyer and add exact vol. of 0.4% EDTA soln required for Ca detn. Titr. with 0.1% EDTA soln as in 1.023(b).

% Mg = (Titer EDTA std soln for Mg)  $\times$  mL EDTA std 0.1% soln  $\times$  2/g sample.

#### Colorimetric Methods (12)—Official Final Action

(Carry reagent blanks thru detn with stds and samples. Treat aliquots of blank soln (corresponding to aliquot sizes of sample solns taken for analysis) as in *Determination* for appropriate element and correct values for samples accordingly.)

Det. Al, Fe, Mn, P, and Ti in solns prepd by HClO<sub>4</sub> digestion, 1.016–1.017, or NaOH fusion, 1.025. Det. Si only in soln prepd by NaOH fusion.

#### 1.025 Preparation of Sample Solution by Sodium Hydroxide Fusion

Prep. samples as in 1.003, preferably in agate mortar. Grind samples to pass No. 100 sieve and dry at 105°.

(a) *Sample Soln X*.—(0.005 g limestone or 0.002 g silicate/mL.) Place 0.5 g limestone or 0.2 g silicate in 75 mL Ni crucible. If sample contains org. matter, place uncovered crucible in cold furnace, raise temp. gradually to 900°, and hold 15 min. Remove crucible from furnace and let cool. Mix 0.3 g KNO<sub>3</sub> with sample and add 1.5 g NaOH pellets. Cover crucible with Ni cover and heat 5 min at dull redness over gas flame. (Do not fuse in furnace.) Remove from flame and swirl melt around sides. Cool, add ca 50 mL H<sub>2</sub>O, and warm to disintegrate fused cake. Transfer to 150 mL beaker contg 15 mL 5*N* HClO<sub>4</sub> (1(60%)+1). Scrub crucible and lid with policeman, and wash any residue into beaker. Transfer to 100 mL vol. flask and dil. to vol. (*Sample Soln X*). (This soln is acidic and is normally clear and free of insol. matter. Occasionally particles of oxidized Ni from crucible appear. When this occurs, let particles settle before taking aliquots.)

(b) *Sample Soln Y*.—(0.00015 g limestone or 0.00004 g silicate/mL.) Dil. 15 mL limestone *Sample Soln X* or 10 mL silicate *Sample Soln X* to 500 mL with H<sub>2</sub>O.

#### Aluminum

##### 1.026

##### Reagents

(a) *Aluminum std solns*.—(1) *Stock soln*.—100  $\mu$ g Al/mL. To 0.1000 g pure Al metal in 30 mL beaker, add 6 mL HCl (1+1). Cover with watch glass and warm gently until Al completely dissolves. Dil. to 1 L with H<sub>2</sub>O. (2) *Working soln*.—4  $\mu$ g Al/mL. Dil. 20 mL stock soln to 500 mL.

(b) *Aluminon soln*.—Dissolve sep. in H<sub>2</sub>O: 0.5 g NH<sub>4</sub> aurintricarboxylate in 100 mL; 10 g acacia (gum arabic) in 200 mL; and 100 g NH<sub>4</sub>OAc in 400 mL. Filter acacia soln. Add 56 mL HCl to NH<sub>4</sub>OAc soln and adjust pH to 4.5 with HCl or NH<sub>4</sub>OH. Combine 3 solns and dil. to 1 L with H<sub>2</sub>O.

(c) *Antifoam soln*.—Disperse 0.03 g silicone defoamer (Dow Corning Corp. Antifoam A) in 100 mL H<sub>2</sub>O.

(d) *Thioglycolic acid soln*.—Dil. 1 mL HSCH<sub>2</sub>COOH to 100 mL with H<sub>2</sub>O.

##### 1.027

##### Preparation of Standard Curve

Transfer aliquots of std soln contg 0, 4, 20, 40, 60, and 80  $\mu$ g Al to 100 mL vol. flasks and proceed as in detn. Prep. std curve by plotting %*T* against  $\mu$ g Al on semilog paper.

##### 1.028

##### Determination

Use *Sample Soln X* for limestones contg <0.2% or silicates

contg <0.8% Al and adjust pH of aliquot to 4.5 with NH<sub>4</sub>OH. For materials contg greater concns of Al, use *Sample Soln Y* and omit pH adjustment.

Transfer aliquot ( $\leq$ 20 mL contg <80  $\mu$ g Al) of *Sample Soln X* or *Y* to 100 mL vol. flask. Dil. to 20 mL with H<sub>2</sub>O. Add 2 mL thioglycolic acid soln, 0.5 mL antifoam soln, and 10 mL aluminon soln. Place flask in boiling H<sub>2</sub>O 20 min (250 mL beaker contg 125 mL H<sub>2</sub>O holds 100 mL vol. flask conveniently). Remove flask from H<sub>2</sub>O and let cool ca 30 min. Dil. to 100 mL with H<sub>2</sub>O. Use 0  $\mu$ g Al soln, 1.027, to set 100% *T* at 525 nm. Read %*T* for sample soln and det.  $\mu$ g Al from std. curve. Calc. % Al in sample.

#### Iron

##### 1.029

##### Reagents

(a) *Iron std solns*.—(1) *Stock soln*.—100  $\mu$ g Fe/mL. Dissolve 0.1000 g pure Fe metal in 5 mL 2*N* HCl and dil. to 1 L with H<sub>2</sub>O. (2) *Working soln*.—5  $\mu$ g Fe/mL. Dil. 25 mL stock soln to 500 mL.

(b) *2,4,6-Tripyridyl-s-triazine (TPTZ) soln*.—(Available from G. Frederick Smith Chemical Co.) Dissolve 0.500 g TPTZ in few drops HCl and dil. to 1 L with H<sub>2</sub>O.

(c) *Hydroxylamine hydrochloride soln*.—Dissolve 50 g NH<sub>2</sub>OH.HCl in H<sub>2</sub>O. Add 10 mL TPTZ soln and 0.5 g NaClO<sub>4</sub>.H<sub>2</sub>O, and dil. to 500 mL with H<sub>2</sub>O. Transfer to separator, add 25 mL *nitrobenzene*, and shake several min. Let phases sep. and discard lower nitrobenzene phase contg Fe. Repeat extrn 2 or 3 times.

(d) *Acetate buffer soln*.—Dissolve 164 g anhyd. NaOAc in H<sub>2</sub>O. Add 115 mL HOAc, 10 mL NH<sub>2</sub>OH.HCl soln, 0.05 g TPTZ, and 1 g NaClO<sub>4</sub>.H<sub>2</sub>O, and dil. to 1 L with H<sub>2</sub>O. Transfer to separator, add 25 mL *nitrobenzene*, and shake several min. Let phases sep. and discard lower nitrobenzene phase. Repeat extrn 3 or 4 times.

##### 1.030

##### Preparation of Standard Curve

Treat aliquots of std soln contg 0, 5, 50, and 100  $\mu$ g Fe as in detn. Prep. std curve by plotting %*T* against  $\mu$ g Fe on semilog paper.

##### 1.031

##### Determination

Use *Sample Soln X* ( $\leq$ 5 mL) for limestones contg <0.05% or silicates contg <0.2% Fe and *Sample Soln Y* for materials contg greater concns of Fe.

Transfer aliquot (<100  $\mu$ g Fe) of *Sample Soln X* or *Y* to 100 mL vol. flask. Add 3 mL NH<sub>2</sub>OH.HCl soln and 10 mL TPTZ soln. Add NH<sub>4</sub>OH dropwise until Fe derivative remains violet on mixing. Add 10 mL buffer soln and dil. to 100 mL. Use 0  $\mu$ g Fe soln, 1.030, to set 100% *T* at 593 nm. Read %*T* for sample soln and det.  $\mu$ g Fe from std curve. Calc. % Fe in sample.

#### Manganese

##### 1.032

##### Reagents

(a) *Manganese std soln*.—50  $\mu$ g Mn/mL. Dissolve 0.0500 g pure Mn metal in 20 mL 0.5*N* H<sub>2</sub>SO<sub>4</sub> and dil. to 1 L with H<sub>2</sub>O.

(b) *Acid mixture*.—Add 800 mL HNO<sub>3</sub> and 200 mL H<sub>3</sub>PO<sub>4</sub> to H<sub>2</sub>O and dil. to 2 L.

##### 1.033

##### Preparation of Standard Curve

Treat aliquots of std soln contg 0, 50, 100, 300, and 500  $\mu$ g Mn as in detn. Prep. std curve by plotting %*T* against  $\mu$ g Mn on semilog paper.

## 1.034

**Determination**

Transfer aliquot (<500  $\mu\text{g}$  Mn) of *Sample Soln X* to 150 mL beaker. Add 25 mL acid mixt. and 0.3 g  $\text{KIO}_4$ . Bring to bp and keep near boiling temp. 10 min after color develops. Let cool, transfer to 50 mL vol. flask, dil. to vol., and mix. Use 0  $\mu\text{g}$  Mn soln, **1.033**, to set 100% *T* at 525 nm. Read %*T* for sample soln and det.  $\mu\text{g}$  Mn from std curve. Calc. % Mn in sample.

**Phosphorus**

(Do not clean glassware with detergents contg P.)

## 1.035

**Reagents**

(a) *Phosphorus std solns.*—(1) *Stock soln.*—100  $\mu\text{g}$  P/mL. Dissolve 0.4393 g  $\text{KH}_2\text{PO}_4$  in  $\text{H}_2\text{O}$  and dil. to 1 L. (2) *Working soln.*—5  $\mu\text{g}$  P/mL. Dil. 25 mL stock soln to 500 mL.

(b) *Ammonium molybdate soln.*—Dissolve 20 g  $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$  in 500 mL  $\text{H}_2\text{O}$ . Add 285 mL  $\text{H}_2\text{SO}_4$ , cool, and dil. to 1 L with  $\text{H}_2\text{O}$ .

(c) *Hydrazine sulfate soln.*—Dissolve 2 g  $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

## 1.036

**Preparation of Standard Curve**

Treat aliquots of std soln contg 0, 5, 50, and 75  $\mu\text{g}$  P as in detn. Prep. std curve by plotting %*T* against  $\mu\text{g}$  P on semilog paper.

## 1.037

**Determination**

Transfer aliquot ( $\leq 15$  mL contg <75  $\mu\text{g}$  P) of *Sample Soln X* to 100 mL vol. flask. Add 5 mL  $\text{NH}_4$  molybdate soln and mix. Add 5 mL  $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$  soln, dil. to 70 mL with  $\text{H}_2\text{O}$ , and mix. Place flask in boiling  $\text{H}_2\text{O}$  9 min. Remove, *cool rapidly*, and dil. to vol. Use 0  $\mu\text{g}$  P soln, **1.036**, to set 100% *T* at 827 nm. Read %*T* for sample soln and det.  $\mu\text{g}$  P from std curve. Calc. % P in sample.

**Titanium**

## 1.038

**Reagents**

(a) *Titanium std solns.*—(1) *Stock soln.*—100  $\mu\text{g}$  Ti/mL. Place 0.1668 g  $\text{TiO}_2$  and 2 g  $\text{K}_2\text{S}_2\text{O}_7$  in Pt crucible. Heat covered crucible gently at first and then at dull red ca 15 min. Dissolve melt in 50 mL  $\text{H}_2\text{SO}_4$  (1+1) and dil. to 1 L with  $\text{H}_2\text{O}$ . (2) *Working soln.*—5  $\mu\text{g}$  Ti/mL. Dil. 25 mL stock soln to 500 mL.

(b) *Acetate buffer soln.*—pH 4.7. Dissolve 41 g anhyd. NaOAc in  $\text{H}_2\text{O}$ , add 30 mL HOAc, and dil. to 1 L.

(c) *Disodium-1,2-dihydroxybenzene-3,5-disulfonate (Tiron) soln.*—Dissolve 4 g Tiron in  $\text{H}_2\text{O}$  and dil. to 100 mL.

## 1.039

**Preparation of Standard Curve**

Treat aliquots of std soln contg 0, 5, 50, and 75  $\mu\text{g}$  Ti as in detn, but do not add dithionite to stds. Prep. std curve by plotting %*T* against  $\mu\text{g}$  Ti on semilog paper.

## 1.040

**Determination**

Transfer aliquot (<75  $\mu\text{g}$  Ti) of *Sample Soln X* to 50 mL beaker. Dil. to ca 25 mL with  $\text{H}_2\text{O}$ . Add 5 mL Tiron soln and then  $\text{NH}_4\text{OH}$  (1+9) dropwise until soln is neut. to Congo Red paper. (Tiron

soln must be added before pH is adjusted.) Transfer to 50 mL vol. flask, add 5 mL buffer soln, dil. to vol. with  $\text{H}_2\text{O}$ , and mix thoroly. Add 25 mg *dithionite* ( $\text{Na}_2\text{S}_2\text{O}_4$ ) and dissolve with min. agitation (to avoid reappearance of blue). Use 0  $\mu\text{g}$  Ti soln, **1.039**, to set 100% *T* at 410 nm. Read %*T* for sample soln within 15 min after adding dithionite. Det.  $\mu\text{g}$  Ti from std curve. Calc. % Ti in sample.

**Silicon**

(Clean all glassware with HCl (1+1).)

## 1.041

**Reagents**

(a) *Silicon std soln.*—20  $\mu\text{g}$  Si/mL. Place 0.0428 g pure  $\text{SiO}_2$  in 75 mL Ni crucible and treat as in **1.025(a)**, but dil. with  $\text{H}_2\text{O}$  to 1 L instead of 100 mL.

(b) *Tartaric acid soln.*—Dissolve 50 g tartaric acid in  $\text{H}_2\text{O}$  and dil. to 500 mL. Store in plastic bottle.

(c) *Ammonium molybdate soln.*—Dissolve 7.5 g  $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$  in 75 mL  $\text{H}_2\text{O}$ , add 10 mL  $\text{H}_2\text{SO}_4$  (1+1), and dil. to 100 mL with  $\text{H}_2\text{O}$ . Store in plastic bottle.

(d) *Reducing soln.*—Dissolve 0.7 g  $\text{Na}_2\text{SO}_3$  in 10 mL  $\text{H}_2\text{O}$ . Add 0.15 g 1-amino-2-naphthol-4-sulfonic acid and stir until dissolved. Dissolve 9 g  $\text{NaHSO}_3$  in 90 mL  $\text{H}_2\text{O}$ , add to first soln, and mix. Store in plastic bottle.

## 1.042

**Preparation of Standard Curve**

Treat aliquots of std soln contg 0, 20, 100, and 200  $\mu\text{g}$  Si as in detn. Prep. std curve by plotting %*T* against  $\mu\text{g}$  Si on semilog paper.

## 1.043

**Determination**

Transfer 10 mL *Sample Soln Y* to 100 mL vol. flask (use *Sample Soln X* for limestones contg <0.2% Si) and add 1 mL  $\text{NH}_4$  molybdate soln with swirling. Mix well, and let stand 10 min. Add 4 mL tartaric acid soln with swirling, and mix well. Add 1 mL reducing soln with swirling, dil. to vol., mix well, and let stand  $\geq 30$  min. Use 0  $\mu\text{g}$  Si soln, **1.042**, to set 100% *T* at 650 nm. Read %*T* for sample soln and det.  $\mu\text{g}$  Si from std curve. Calc. % Si in sample.

## 2. Fertilizers

### Sampling—Official Final Action

#### 2.001 Solid Fertilizers (1)

(a) *Bagged fertilizers.*—Use slotted single or double tube trier with solid cone tip, constructed of stainless steel or brass. (Do not use unplated brass for samples on which micronutrients are to be detd.) Trier length, exclusive of handle, should be approx. length of filled bag to be sampled, but  $>25''$ ; length of slot,  $>23''$ ; width of slot  $\geq 0.5''$ ; and id  $\geq \frac{5}{8}''$ .

Take sample as follows: Lay bag horizontally and remove core diagonally from end to end. From lots of  $\geq 10$  bags, take core from each of 10 bags. When necessary to sample lots of  $<10$  bags, take 10 cores but at least 1 core from each bag present. For small packages ( $\leq 10$  lb), take 1 entire package as sample.

(b) *Bulk fertilizers, including railroad car-size lots.*—Use trier of design represented in Table 2:01.

Table 2:01 Trier specifications

Trier	Length, in.	od, in.	id, in.	Compartments	
				No.	Size, in.
Missouri	59	1 $\frac{1}{8}$	$\frac{7}{8}$	8	3
552 Grain <sup>a</sup>	63	1 $\frac{3}{8}$	1 $\frac{1}{8}$	11	3 $\frac{1}{2}$
Missouri "D" <sup>b</sup>	52	1 $\frac{1}{4}$	1	1	45

Triers available from:

<sup>a</sup> Seedboro Equipment Co., 618 W Jackson Blvd, Chicago, IL 60606.

<sup>b</sup> American Tool and Die, Inc., 1105 Maple St, West Des Moines, IA 50265.

Draw 10 vertical cores distributed in std concentric sampling pattern (Fig. 2:01) of such design that each core represents approx. equal fractions of lot.

Bulk shipments may be sampled at time of loading or unloading by passing sampling cup, Fig. 2:02 (mouth dimensions: width  $\frac{3}{4}''$ , length 16" or as long as max. diam. of stream), thru entire stream of material as it drops from belt or chute. Make

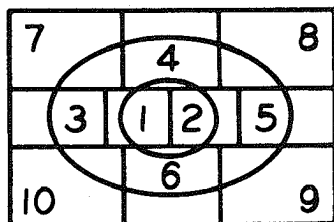

FIG. 2:01—Sampling pattern

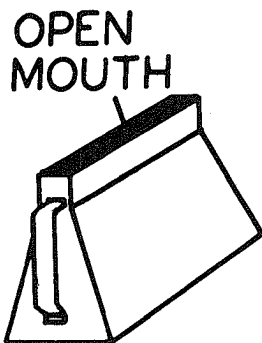

FIG. 2:02—Sampling cup

sampling such as to assure  $\geq 10$  equal-timed-spaced passes thruout transfer operation. Stream samples are not applicable unless uniform continuous flow of fertilizer is maintained for  $>3$  min while lot is being sampled.

(c) *Preparation of sample.*—Place composite sample in air-tight container and deliver entire sample to laboratory. Reduce composite sample in laboratory, using riffle.

#### 2.002 Liquid Fertilizers (2)

##### (In Absence of Free Ammonia)

(a) *Clear solns.*—(Mixed liqs and N solns.) Secure sample directly from mixing vat, storage tank, or delivery tank after thoro mixing. Take sample from surface or thru direct tap. Flush direct tap, or delivery line and faucet, and collect sample in glass or polyethylene container. Alternatively, lower sample container into well mixed material thru port in top of tank and let fill. Seal container tightly.

(b) *Fluid fertilizers with suspended material.*—(Salt suspensions and slurries.) Agitate material in storage until thoroly mixed (15 min usually adequate) before taking sample. Sample directly as in (a), or use 500 mL Missouri or Indiana sampling bottle, Fig. 2:03. Lower sampling bottle from top opening to bottom of tank and raise slowly while filling. Transfer to sample bottle and seal tightly.

Alternatively, secure sample from tap on recirculation line after agitating and recirculating simultaneously until thoroly mixed. Draw sample while recirculating. If recirculation line is

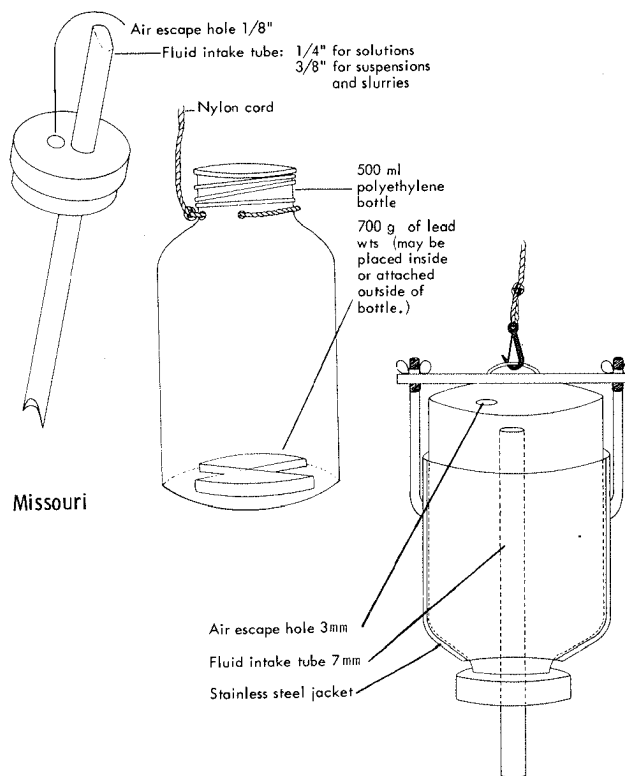

FIG. 2:03—Missouri and Indiana weighted restricted-fill fluid fertilizer sampling bottles designed to fill while being lowered (and raised) in storage tanks

attached to manifold delivery line, allowing cross-contamination, pump ca 30 cm (1') or 2000 L (500 gal.) into temporary storage tank, then sample from recirculation line as above or from delivery line. Transfer to sample bottle and seal tightly.

### Ammoniacal Solutions (3)

#### 2.003

#### Apparatus

(a) *Container*.—Polyethylene reagent-form bottle with buttress-type cap, 1 L (1 qt) capacity.

(b) *Sample flow control apparatus*.—Construct from following fittings:  $1\frac{1}{2} \times \frac{1}{4}$ " reducing bushing;  $\frac{1}{4}$ " tee;  $\frac{1}{4}$ " nipple 12–18" long (length not critical); two  $\frac{1}{4}$ " stainless steel, blunt-nose needle valves with hose connections (Hoke No. 328; Hoke Inc., 1 Tenakill Pk, Cresskill, NJ 07626). All fittings except valves can be either Al or stainless steel. (See Fig. 2:04.)

Attach valves directly to tee which is then attached to reducing bushing thru nipple. To both valves attach  $\frac{1}{4}$ " id Tygon tubing (Hoke No. 314A hose connection), 12" length to sample valve and sufficient length to vent valve to reach disposal area or container. To free end of sample tubing attach 3" length of  $\frac{1}{4}$ " glass or stainless steel tubing inserted thru No. 4 rubber stopper. To exit end of metal tube attach addnl 6" length of Tygon tubing. Make certain all connections are tight. App. can be attached directly to tank cars, but requires addnl coupling, which varies with installation, to attach to storage tanks.  $1\frac{1}{2}$ " "quick coupler" (Ever-Tite Coupling Co., 254 W 54th St, New York, NY 10019) suffices in most cases.

#### 2.004

#### Sampling

Prep. sample bottle in laboratory by adding ca 500 mL  $H_2O$ , replacing cap, and weighing accurately ( $\pm 0.1$  g). Attach sampling app. to car or tank and, with sample valve closed, flush line thru vent valve. Partially collapse sample bottle, insert sample tube with stopper, and seat tightly. With sample tube dipping below surface of  $H_2O$  in bottle, throttle vent valve to maintain small flow of soln and partially open sample valve, collecting ca 100 mL sample. (Bottle should not expand to full size during this

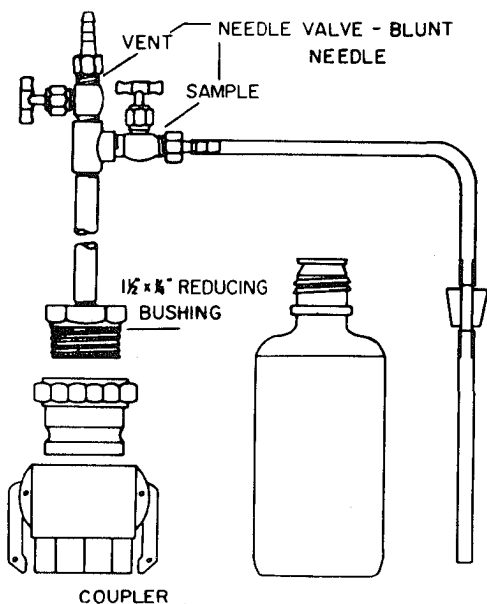

FIG. 2:04—Sampling apparatus for ammoniacal solutions, including "quick coupler" for attaching to storage tanks

time.) Close sample valve, remove sample tube, partially collapse bottle, and cap tightly. Reweigh ( $\pm 0.1$  g) and calc. wt sample. Cool to  $20^\circ$ , transfer to 1 or 2 L vol. flask, dil. to vol. with  $H_2O$ , mix thoroly, and take aliquots for analysis.

### Anhydrous Ammonia (3)

(Caution: Use extreme care in handling anhyd.  $NH_3$ . Suitable gas mask and rubber gloves are required. See 51.032.)

#### 2.005

#### Sampling

Use sample tube of thermal shock-resistant glass calibrated to contain 100 mL and graduated in 0.05 mL subdivisions up to 0.5 mL. (Dupont special oil centr. tube or ASTM long-form oil tube is satisfactory.) Flush line and fill tube to 100 mL mark with sample in such manner that condensing moisture will not enter sample tube. (Skirt attached to end of sample line will drain moisture away.)

#### 2.006

#### Water and Nitrogen

Immediately close sample tube with tight-fitting rubber stopper into which is inserted tight-fitting piece of 6 mm id glass tubing 5–8 cm long, bent at its exit from outer end of stopper to let gases escape but to exclude entrance of moisture or moisture-laden air. Place in  $H_2O$  bath at approx. air temp. and let  $NH_3$  evap. When temp. of sample tube is ca that of bath, remove tube, wipe outer surface, and det. vol. of residue.

$$\% H_2O \text{ in sample} = \text{mL residue} \times C,$$

where  $C = 0.74, 0.70$ , or  $0.66$  for pressures in original containers of 100, 150, or 200 psi, resp.

$$\% N = (100 - \% H_2O) \times 0.8224.$$

#### 2.007 Preparation of Sample (4)—Official Final Action

Reduce gross sample to amt sufficient for analysis or grind  $\geq 225$  g (0.5 lb) of reduced sample without previous sieving. For fertilizer materials and moist fertilizer mixts, grind to pass sieve with 1 mm circular openings, or No. 20 sieve; for dry mixts that tend to segregate, grind to pass No. 40 sieve. Grind as rapidly as possible to avoid loss or gain of moisture during operation. Mix thoroly and store in tightly stoppered bottles.

#### 2.008 ★ Mechanical Analysis of Bone, Tankage, and ★ Basic Slag (5)—Official Final Action

Sieve thru circular openings 0.5 mm diam. See 2.008, 11th ed.

#### Mechanical Analysis of Phosphate Rock (6) Official Final Action

#### 2.009

#### Apparatus

(a) *Water pressure control*.—See Fig. 2:05. Connect valve, A, std pressure gage, B, and aerator, C, with  $\frac{3}{8}$ " diam. pipe.

(b) *Sieves*.—Nos. 100 and 200, bronze or stainless steel cloth, checked against certified sieves. Sieves 8" diam. and 2" in depth to sieve cloth are recommended for both wet and dry sieving, but other sizes may be used if detd to be suitable under conditions of method. (Other sieves in U.S. series may be used, with precaution to ensure complete sepn of sample into desired fractions.)

(c) *Sieve shaker*.—Ro-Tap (W. S. Tyler, Inc., 8200 Tyler Blvd, Mentor, OH 44060), Syntron (FMC Corp., Material Handling

★ Surplus method—see inside front cover.

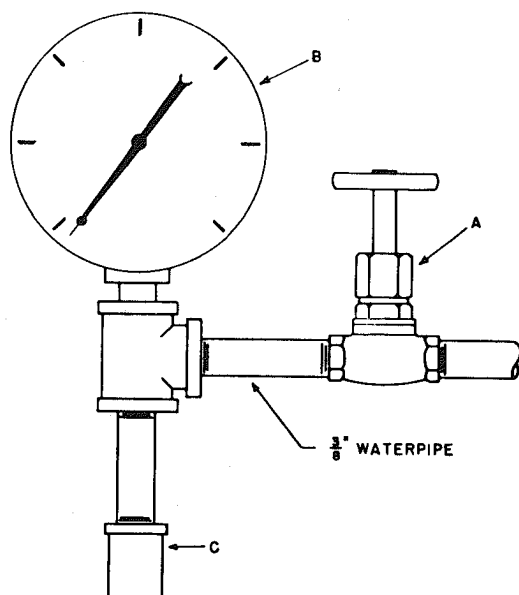

FIG. 2.05—Apparatus for control of water pressure

Equipment Div., Homer City, PA 15748), or other suitable machine.

**2.010****Reagent**

**Dispersing agent.**—Dissolve 36 g Na hexametaphosphate and 8 g  $\text{Na}_2\text{CO}_3$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

**2.011****Determination**

(a) **Ground phosphate rock.**—Place 100 g sample on No. 200 sieve and wash with moderate stream of tap  $\text{H}_2\text{O}$  at max. gage pressure of 0.28 kg/sq cm (4 lb/sq in.) until  $\text{H}_2\text{O}$  passing sieve is clear, with care to avoid loss of sample by splashing. Dry material remaining on sieve at  $105^\circ$  and transfer to No. 100 sieve in series with No. 200 sieve of same diam. and depth. Shake 8 min in mech. shaker. Det. % sample passing No. 100 sieve by subtracting wt of material retained on that sieve from 100. Det. % sample passing No. 200 sieve by subtracting sum of wts of material retained on that sieve and on No. 100 sieve from 100.

(b) **Soft phosphate with colloidal clay.**—Add 100 g sample to rapidly stirred soln of 50 mL dispersing agent and 450 mL tap  $\text{H}_2\text{O}$ , with care to avoid contact of unwetted material with shaft of stirrer and side of beaker. Stir 5 min after addn of sample is completed. Transfer slurry to No. 200 sieve and proceed as in (a).

**2.012 Total Water—Official Final Action**

(Not applicable to samples that yield volatile substances other than  $\text{H}_2\text{O}$  at drying temp.)

Heat 2 g sample, **2.007**, 5 hr in oven at  $100 \pm 1^\circ$ . In case of  $\text{NaNO}_3$ ,  $(\text{NH}_4)_2\text{SO}_4$ , and K salts, heat to const wt at  $130 \pm 1^\circ$ . Report % loss in wt as  $\text{H}_2\text{O}$  at temp. used.

**FREE WATER****Vacuum-Desiccation Methods (7)****2.013 Method I—Official Final Action**

Place 2 g prepd sample, **2.007**, in tared weighing dish. (Weigh extremely hygroscopic or damp materials by difference in covered dishes.) Dry sample at  $25\text{--}30^\circ$  (precise results depend on as const a temp. as possible) in vac. desiccator over anhyd.

$\text{Mg}(\text{ClO}_4)_2$ ,  $\text{P}_2\text{O}_5$ , or  $\text{BaO}$ , under  $\geq 50$  cm (20") or  $\leq 55$  cm (22") vac. (20–25 cm (8–10") absolute pressure) 16–18 hr. Reweigh, and report % loss in wt as free  $\text{H}_2\text{O}$ .

**2.014 Method II—Official Final Action**

(Not applicable to samples which yield volatile substances other than  $\text{H}_2\text{O}$ )

Weigh 2 g prepd sample, **2.007**, into tared glass weighing dish. Dry sample 2 hr  $\pm 10$  min at  $50 \pm 1.5^\circ$  in oven under vac. of 48–53 cm (19–21") (23–28 cm (9–11") absolute pressure). (Temp. control within specified limits thruout oven chamber is essential.) Maintain vac. by passing desiccated air thru chamber. Cool dried sample in desiccator and reweigh. Report % loss in wt as free  $\text{H}_2\text{O}$ .

**Alternative Extraction Method (8)****Official Final Action****2.015****Principle**

Free  $\text{H}_2\text{O}$  is extd with dioxane and detd by titrn with Karl Fischer reagent.

**2.016****Reagents**

(Keep exposure of org. reagents to air at min.)

(a) **Karl Fischer reagent.**—Stabilized single soln (Fisher Scientific Co., So-K-3, or equiv.) dild ca 1 + 1 with stabilized diluent (Fisher, So-K-5, or equiv.), or soln equiv. to 2.5 mg  $\text{H}_2\text{O}$ /mL. Stdze daily with ca 0.2 g Na tartrate. $\cdot 2\text{H}_2\text{O}$ . 1 mg Na tartrate. $\cdot 2\text{H}_2\text{O}$  = 0.1566 mg  $\text{H}_2\text{O}$ .

(b) **Methanol.**—Low in  $\text{H}_2\text{O}$ .

**2.017****Determination**

Accurately weigh 2.5 g prepd sample, **2.007**, into 125 mL erlenmeyer, add 50.0 mL 1,4-dioxane, stopper, mix by swirling, and let stand 15 min. Mix thoroly by swirling, and centr. in closed tube. (Caution: See 51.005.)

Transfer 10 mL aliquot to titrn vessel contg pretitr. MeOH and titr. with Karl Fischer reagent. (Discard contents of titrn vessel after 3 titrns, replace with enough MeOH to cover electrodes, and pretitr. before proceeding with next sample.) Det. blank on 10 mL dioxane as above and subtract from sample detns. Calc. and report as free  $\text{H}_2\text{O}$ .

**2.018 ★ Acid-Insoluble Ash (9) ★****Official Final Action**

HCl (1+4) digestion at  $100^\circ$ , ignition at  $800^\circ$ , and redigestion. See 2.015, 11th ed.

**PHOSPHORUS****Total Phosphorus****2.019****Reagent**

**Magnesium nitrate soln.**—Dissolve 950 g P-free  $\text{Mg}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

**2.020****Preparation of Solution—Official Final Action**

(Caution: See 51.019, 51.026, 51.028, 51.030, and 51.069.)

Treat 1 g sample by (a), (b), (c), (d), or (e), as indicated. Cool soln, transfer to 200 or 250 mL vol. flask, dil. to vol., mix, and filter thru dry filter.

★ Surplus method—see inside front cover.

(a) *Materials containing small quantities of organic matter.*—Dissolve in 30 mL  $\text{HNO}_3$  and 3–5 mL  $\text{HCl}$ , and boil until org. matter is destroyed (30 min for liqs and suspensions).

★(b) *Fertilizers containing much Fe or Al phosphate, and basic slag.*★—Dissolve in 15–30 mL  $\text{HCl}$  and 3–10 mL  $\text{HNO}_3$ .

(c) *Organic material like cottonseed meal alone or in mixtures.*—Evap. with 5 mL  $\text{Mg}(\text{NO}_3)_2$  soln, 2.019, ignite, and dissolve in  $\text{HCl}$ .

★(d) *Materials or mixtures containing large amounts of organic matter.*★—Digestion with  $\text{H}_2\text{SO}_4$  and  $\text{NaNO}_3$  or  $\text{KNO}_3$ . See 2.017(d), 11th ed.

(e) *All fertilizers.*—Boil gently 30–45 min with 20–30 mL  $\text{HNO}_3$  in suitable flask (preferably Kjeldahl for samples contg large amts of org. matter) to oxidize all easily oxidizable matter. Cool. Add 10–20 mL 70–72%  $\text{HClO}_4$ . Boil very gently until soln is colorless or nearly so and dense white fumes appear in flask. Do not boil to dryness at any time (Danger!). (With samples contg large amts of org. matter, raise temp. to fuming point, ca  $170^\circ$ , over period of  $\geq 1$  hr.) Cool slightly, add 50 mL  $\text{H}_2\text{O}$ , and boil few min.

#### **Spectrophotometric Molybdovanadophosphate Method (10)—Official Final Action**

(Not applicable to materials yielding colored solns or solns contg ions other than orthophosphate which form colored complexes with molybdovanadate. Not recommended for basic slag.)

#### **2.021**

#### **Apparatus**

*Photometer.*—Beckman Instruments, Inc. Model DU (current models 24/25) spectrophtr with stray light filter and matched 1 cm cells. With other photometers analyst must det. suitability for use and conditions for satisfactory performance. Means for dissipating heat from light source is desirable.

#### **2.022**

#### **Reagents**

(a) *Molybdovanadate reagent.*—Dissolve 40 g  $\text{NH}_4$  molybdate.  $4\text{H}_2\text{O}$  in 400 mL hot  $\text{H}_2\text{O}$  and cool. Dissolve 2 g  $\text{NH}_4$  metavanadate in 250 mL hot  $\text{H}_2\text{O}$ , cool, and add 450 mL 70%  $\text{HClO}_4$ . (Caution: See 51.028(a) and (d).) Gradually add molybdate soln to vanadate soln with stirring, and dil. to 2 L.

(b) *Phosphate std soln.*—Dry pure  $\text{KH}_2\text{PO}_4$  (52.15%  $\text{P}_2\text{O}_5$ ) 2 hr at  $105^\circ$ . Prep. solns contg 0.4–1.0 mg  $\text{P}_2\text{O}_5$ /mL in 0.1 mg increments by weighing 0.0767, 0.0959, 0.1151, 0.1342, 0.1534, 0.1726, and 0.1918 g  $\text{KH}_2\text{PO}_4$  and dilg each to 100 mL with  $\text{H}_2\text{O}$ . Prep. fresh solns contg 0.4 and 0.7 mg  $\text{P}_2\text{O}_5$ /mL weekly.

#### **2.023**

#### **Preparation of Standard Curve**

Pipet 5 mL aliquots of 7 std phosphate solns (2–5 mg  $\text{P}_2\text{O}_5$ /aliquot) into 100 mL vol. flasks and add 45 mL  $\text{H}_2\text{O}$ . Then, within 5 min for entire series, add 20 mL molybdovanadate reagent by buret or pipet, dil. to vol. and mix. Let stand 10 min.

Select 2 absorption cells (std and sample cells) and fill both with 2 mg std. Set spectrophtr to 400 nm and adjust to zero  $A$  with std cell. Sample cell must check zero  $A$  within 0.001 unit; otherwise read  $A$  for sample cell and correct subsequent readings. (Choose cell showing pos.  $A$  against other as sample cell so that this pos.  $A$  is always subtracted.) Using sample cell, det.  $A$  of other stds with instrument adjusted to zero  $A$  for 2 mg std. After each detn empty and refill cell contg 2 mg std, and readjust zero to avoid error that might arise from temp. changes. Plot  $A$  against concn in mg  $\text{P}_2\text{O}_5$ /mL std soln.

★ Surplus method—see inside front cover.

#### **2.024**

#### **Preparation of Solution**

Treat 1 g sample as in 2.020, preferably (e), when these acids are suitable solv. (Soln should be free of N oxides and  $\text{NOCl}$ .)

(a) For  $\text{P}_2\text{O}_5$  content  $\leq 5\%$ , dil. to 250 mL.

(b) For  $\text{P}_2\text{O}_5$  content  $> 5\%$ , dil. to such vol. that 5 or 10 mL aliquot contains 2–5 mg  $\text{P}_2\text{O}_5$ .

#### **2.025**

#### **Determination**

Pipet, into 100 mL vol. flasks, 5 mL aliquots of std phosphate solns contg 2 and 3.5 mg  $\text{P}_2\text{O}_5$ /aliquot, resp., and develop color as in 2.023. Adjust instrument to zero  $A$  for 2 mg std, and det.  $A$  of 3.5 mg std. (It is essential that  $A$  of latter std be practically identical with corresponding value on std curve.)

(a) *Samples containing up to 5%  $\text{P}_2\text{O}_5$ .*—Pipet, into 100 mL vol. flask, 5 mL sample soln, 2.024(a), and 5 mL std phosphate soln contg 2 mg  $\text{P}_2\text{O}_5$ . Develop color and det.  $A$  concurrently with and in same manner as for std phosphate solns in preceding par., with instrument adjusted to zero  $A$  for 2 mg std. Read  $\text{P}_2\text{O}_5$  concn from std curve. With series of sample solns, empty and refill cell contg 2 mg std after each detn.

%  $\text{P}_2\text{O}_5$  in sample =  $100 \times [(\text{mg } \text{P}_2\text{O}_5 \text{ from std curve} - 2)/20]$ .

(b) *Samples containing more than 5%  $\text{P}_2\text{O}_5$ .*—Pipet 5 or 10 mL sample soln, 2.024(b), into 100 mL vol. flask. Without adding std phosphate soln, proceed as in (a).

%  $\text{P}_2\text{O}_5$  in sample =  $100 \times (\text{mg } \text{P}_2\text{O}_5 \text{ from std curve/mg sample in aliquot})$ .

#### **Gravimetric Quinolinium Molybdophosphate Method (11)—Official Final Action**

#### **2.026**

#### **Reagents**

(Store solns in polyethylene bottles.)

(a) *Citric-molybdic acid reagent.*—Dissolve 54 g 100% molybdic anhydride ( $\text{MoO}_3$ ) and 12 g  $\text{NaOH}$  with stirring in 400 mL hot  $\text{H}_2\text{O}$ , and cool. Dissolve 60 g citric acid in mixt. of 140 mL  $\text{HCl}$  and 200 mL  $\text{H}_2\text{O}$ , and cool. Gradually add molybdic soln to citric acid soln with stirring. Cool, filter, and dil. to 1 L. (Soln may be green or blue; color deepens on exposure to light.) If necessary, add 0.5%  $\text{KBrO}_3$  soln dropwise until green color pales. Store in dark.

(b) *Quinoline soln.*—Dissolve 50 mL synthetic quinoline, with stirring, in mixt. of 60 mL  $\text{HCl}$  and 300 mL  $\text{H}_2\text{O}$ . Cool, dil. to 1 L, and filter.

(c) *Quimociac reagent.*—Dissolve 70 g Na molybdate.  $2\text{H}_2\text{O}$  in 150 mL  $\text{H}_2\text{O}$ . Dissolve 60 g citric acid in mixt. of 85 mL  $\text{HNO}_3$  and 150 mL  $\text{H}_2\text{O}$ , and cool. Gradually add molybdate soln to citric acid- $\text{HNO}_3$  mixt. with stirring. Dissolve 5 mL synthetic quinoline in mixt. of 35 mL  $\text{HNO}_3$  and 100 mL  $\text{H}_2\text{O}$ . Gradually add this soln to molybdate-citric acid- $\text{HNO}_3$  soln, mix, and let stand 24 hr. Filter, add 280 mL acetone, dil. to 1 L with  $\text{H}_2\text{O}$ , and mix.

#### **2.027**

#### **Preparation of Solution**

Treat 1 g sample as in 2.020, dilg to 200 mL.

#### **2.028**

#### **Determination**

Pipet, into 500 mL erlenmeyer, aliquot contg  $\leq 25$  mg  $\text{P}_2\text{O}_5$  and dil. to ca 100 mL with  $\text{H}_2\text{O}$ . Continue by one of the following methods:

(a) Add 30 mL citric-molybdic acid reagent and boil gently 3 min. (Soln must be ppt-free at this time.) Remove from heat and swirl carefully. Immediately add 10 mL quinoline soln from buret with continuous swirling. (Add first 3–4 mL dropwise and remainder in steady stream.) Or:

(b) Add 50 mL quimociac reagent, cover with watch glass, place on hot plate in well-ventilated hood, and boil 1 min.

After treatment by (a) or (b), cool to room temp., swirl carefully 3–4 times during cooling, filter into gooch with glass fiber filter paper previously dried at 250° and weighed, and wash with five 25 mL portions of H<sub>2</sub>O. Dry crucible and contents 30 min at 250°, cool in desiccator to room temp., and weigh as (C<sub>8</sub>H<sub>7</sub>N)<sub>3</sub>H<sub>3</sub>[PO<sub>4</sub>·12MoO<sub>3</sub>]. Subtract wt reagent blank. Multiply by 0.03207 to obtain wt P<sub>2</sub>O<sub>5</sub> (or by 0.01400 for P). Report as % P<sub>2</sub>O<sub>5</sub> (or % P).

**Alkalimetric Quinolinium Molybdophosphate  
Method (12)—Official Final Action**

## 2.029

**Reagents**

- (a) *Quimociac reagent*.—See 2.026(c).  
 (b) *Sodium hydroxide std soln*.—(1 mL = 1 mg P<sub>2</sub>O<sub>5</sub>.) Dil. 366.32 mL 1N NaOH, 50.032–50.036, to 1 L with H<sub>2</sub>O.  
 (c) *Nitric acid std soln*.—Prep. HNO<sub>3</sub> soln equiv. to concn of (b) and stdze by titrg against (b), using phthln. (For greater precision, use HNO<sub>3</sub> soln corresponding to 1/5 concn of (b).)  
 (d) *Citric acid*.—10% (w/v).  
 (e) *Indicators*.—(1) *Thymol blue soln*.—0.1%. Add 2.2 mL 0.1N NaOH to 0.1 g thymol blue and dil. to 100 mL with 50% alcohol. (2) *Phenolphthalein*.—0.1%. Dissolve 0.1 g phthln in 100 mL 50% alcohol. (3) *Mixed indicator*.—Mix 3 vols (1) and 2 vols (2).

## 2.030

**Preparation of Sample Solution**

Treat 1 g sample as in 2.020, first par. and (a) or (e).

## 2.031

**Determination**

(a) *Precipitation*.—Transfer aliquot contg ≤30 mg P<sub>2</sub>O<sub>5</sub> and ≤5 mL concd acid to 500 mL erlenmeyer, add 20 mL citric acid soln, and adjust to ca 100 mL. Add 60 mL quimociac reagent, immediately cover with watch glass, and place on medium temp. hot plate. After soln comes to bp, move to cooler portion of hot plate and boil gently 1 min. Let cool until flask can be handled comfortably with bare hand.

(b) *Filtration and washing*.—Prep. pulped-paper pad ca 6 mm thick on perforated porcelain disk in funnel by adding ≥2 approx. equal increments of H<sub>2</sub>O suspension of pulped paper and sucking dry with vac. between addns. Swirl flask, pour contents onto filter, and wash flask with five ca 15 mL portions H<sub>2</sub>O, adding washings to funnel. Immediately after funnel has emptied, wash down sides with ca 15 mL H<sub>2</sub>O to remove residual acetone, which causes excessively fast drying and later lump formation if allowed to evap. Wash with 3 addnl 15 mL portions H<sub>2</sub>O, letting funnel empty between addns. Keep drying of ppt to min. Using only jet of H<sub>2</sub>O, transfer ppt and pad to pptn flask and break up pad with jet of H<sub>2</sub>O. Do not smear ppt against funnel or flask.

(c) *Titration*.—Titr. with std NaOH soln and add 3–5 mL excess. Add 1 mL mixed indicator and titr. with std HNO<sub>3</sub> soln to grey-blue end point. If overtitrd (greenish-yellow), add addnl excess std NaOH soln and titr. to grey-blue.

(d) *Blank*.—Det. blank on all reagents, adding known amt (1–2 mg) of P<sub>2</sub>O<sub>5</sub>. Use 1 + 9 dilns of std NaOH and HNO<sub>3</sub> for titrn and subtract theoretical titer equiv. to P<sub>2</sub>O<sub>5</sub> added from experimental titer. Calc. difference equiv. to 0.3663N NaOH and subtract this blank from all sample detns.

Calc. and report as % P<sub>2</sub>O<sub>5</sub>.

**Automated Method (13)—Official First Action**

## 2.032

**Principle**

Samples are extd for direct available P<sub>2</sub>O<sub>5</sub> or for total P<sub>2</sub>O<sub>5</sub>

detns. Destruction of coloring matter, hydrolysis of nonortho-phosphates, and elimination of citrate effect are accomplished by digestion with 4N HClO<sub>4</sub> at 95°. Digested samples are reacted with molybdovanadate reagent, and A of resulting complex is read in flowcell at 420 nm in range 0.15–0.35 mg P<sub>2</sub>O<sub>5</sub>/mL.

## 2.033

**Apparatus and Reagents**

(Caution: See 51.028.)

(a) *Automatic analyzer*.—AutoAnalyzer with following modules (Technicon Instruments Corp., or equiv.): Sampler II or IV with 40/hr (4:1) cam; proportioning pump III; P<sub>2</sub>O<sub>5</sub> anal. cartridge (with 2 heating baths, each contg 10.6 mL coil held at 95±1°; or AAI type heating bath contg one 40' × 1.6 mm id coil and holding constant temp. of 95±1°); AAI single channel colorimeter with 15 × 1.5 or 2.0 mm id flowcell and 420 nm interference filters; voltage stabilizer; and recorder. Construct manifold as in flow diagram, Fig. 2:06.

(b) *Molybdovanadate reagent*.—Dissolve 16.5 g NH<sub>4</sub> molybdate·4H<sub>2</sub>O in 400 mL hot H<sub>2</sub>O, and cool. Dissolve 0.6 g NH<sub>4</sub> metavanadate in 250 mL hot H<sub>2</sub>O, cool, and add 60 mL 70% HClO<sub>4</sub>. Gradually add molybdate soln to vanadate soln with stirring. Add 2 mL wetting agent, (e), and dil. to 2 L.

(c) *Perchloric acid*.—4N. Add 342 mL 70% HClO<sub>4</sub> to 500 mL H<sub>2</sub>O in 1 L vol. flask. Add 1 mL wetting agent, and dil. to vol.

(d) *Sampler wash soln*.—Add 1 mL wetting agent to 1 L H<sub>2</sub>O, and mix well.

(e) *Wetting agent*.—Ultrawet 60 L (Technicon No. T01-0214), or equiv.

(f) *Phosphorus std solns*.—(1) *Stock soln*.—10 mg P<sub>2</sub>O<sub>5</sub>/mL. Dissolve 9.5880 g dried (2 hr at 105°) KH<sub>2</sub>PO<sub>4</sub> primary std (52.15% P<sub>2</sub>O<sub>5</sub>) in H<sub>2</sub>O, and dil. to 500 mL with H<sub>2</sub>O. (2) *Working solns*.—0.15, 0.19, 0.23, 0.27, 0.31, and 0.35 mg P<sub>2</sub>O<sub>5</sub>/mL. Using 25 mL buret, accurately measure 7.5, 9.5, 11.5, 13.5, 15.5, and 17.5 mL stock soln into six 500 mL vol. flasks. Dil. each to vol. with H<sub>2</sub>O, and mix. (3) *Working soln for samples* ≤7% P<sub>2</sub>O<sub>5</sub>.—2 mg P<sub>2</sub>O<sub>5</sub>/mL. Pipet 100 mL stock soln into 500 mL vol. flask, dil. to vol. with H<sub>2</sub>O, and mix.

## 2.034

**Preparation of Samples**

Prep. samples for direct available P<sub>2</sub>O<sub>5</sub> detn as in 2.050(a). Prep. samples for total P<sub>2</sub>O<sub>5</sub> detn as in 2.020(a) or (e), and dil. to 250 mL.

## 2.035

**Analytical System**

(Technicon part numbers are given to aid in construction of manifold; equiv. coils, fittings, etc., are satisfactory.)

Sample, air, and 4N HClO<sub>4</sub> are combined thru injection fitting (No. 116–0489) and mixed in 20T coil (No. 157–0248). Stream proceeds to heating bath(s) before resample thru modified AO fitting. Resample, air, and molybdovanadate reagent are combined thru injection fitting (No. 116–0489). Mixing and color development takes place in two 20T coils (No. 157–0248) before measurement at 420 nm. If only total P<sub>2</sub>O<sub>5</sub> samples are to be analyzed, heating bath can be removed and 4N HClO<sub>4</sub> soln replaced by sampler wash soln, (d). Heating bath(s) and acid soln are necessary only when analyzing samples for direct available P<sub>2</sub>O<sub>5</sub> or combination of direct available and total P<sub>2</sub>O<sub>5</sub> detns.

If manifold is to be constructed following flow diagram, use clear std pump tubes for all air and soln flows. All fittings, coils, and glass transmission lines are AAI type and size. Use 1.6 mm glass transmission tubing for all connections after pump to colorimeter. Construct modified AO fitting, following heating bath, by using AO fitting, N13 stainless steel nipple connector,

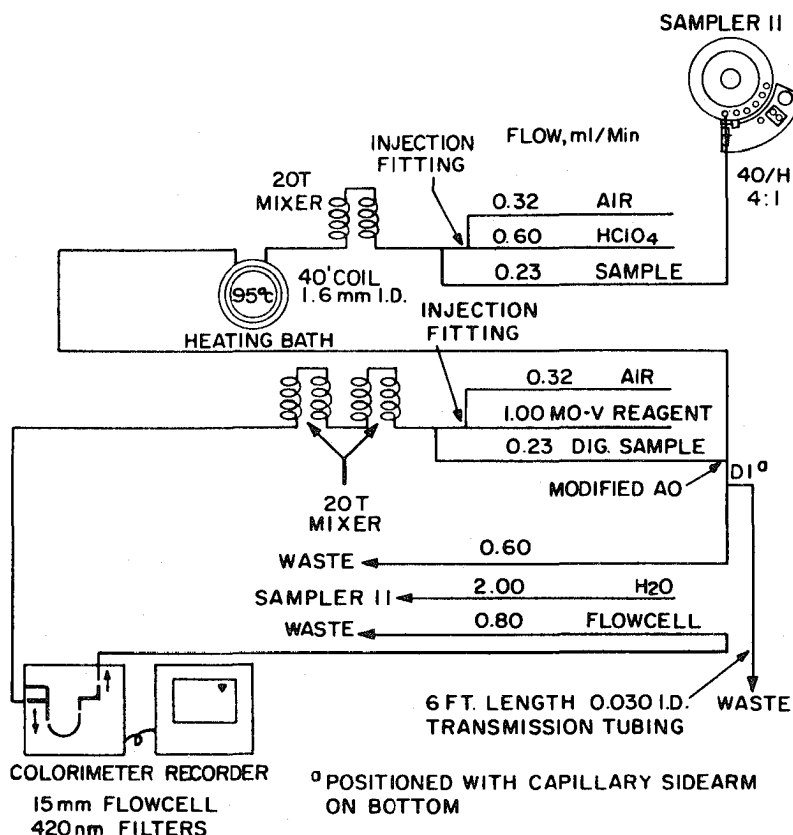

FIG. 2:06—Flow diagram for automated analysis for phosphorus

and 1.3 cm length of 0.035" id Tygon tubing. Insert N13 nipple approx. halfway into 0.035" Tygon tubing. Insert tubing into side arm of AO fitting far enough so resample line will not pump any air. Connect D1 fitting directly to waste side of AO fitting; position D1 fitting with capillary side arm on bottom. Attach 0.6 mL/min pump tube to top arm of D1 fitting, and attach 1.8 m (6') of 0.030" id transmission tubing to bottom arm. All air segments must pass thru 0.6 mL/min tube, leaving continuous column of liq. in 1.8 m length of tubing to provide for constant back pressure on heating bath coil. Length of resample pump tube should be  $\leq 2.5$  cm from shoulder at entrance end.

**2.036****Start-Up**

Start automatic system, place all lines in resp. solns, and let equilibrate  $\geq 30$  min. Proceed as in 2.038.

**2.037****Shut-Down**

Pump water thru reagent lines  $\geq 30$  min. Do not remove  $\text{HClO}_4$  lines from reagent until 20 min after last sample is run.

**2.038****Check and Calibration**

After equilibration, set colorimeter to damp 1 position and pump 0.15 mg  $\text{P}_2\text{O}_5$ /mL working std soln continuously thru system. Adjust colorimeter baseline to read 10% of full scale. Pump 0.35 mg  $\text{P}_2\text{O}_5$ /mL std and adjust std calibration to read 90% of full scale. Range of 0.15–0.35 mg  $\text{P}_2\text{O}_5$ /mL will expand to read 10–90% of full scale. Check of bubble flow pattern will give indication of performance of system. Perfect bubble pattern is required to obtain optimum peak shapes. Check for air bubble in flowcell if noisy conditions exist. To check system carryover,

place three 0.35 mg/mL stds, followed by three 0.15 mg/mL stds thru system. If first 0.15 mg/mL std following 0.35 mg/mL std is  $\geq 1$  chart division higher than other 2, carryover is indicated. If carryover occurs, check entire system for poor connections.

**2.039****Determination**

Pipet aliquot of sample soln (see Table 2:02) into 100 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix by inversion 20 times. For sample contg  $\leq 7\%$   $\text{P}_2\text{O}_5$ , pipet 10 mL working soln, (f)(3), into flask before diln. Place 0.15–0.35 mg  $\text{P}_2\text{O}_5$ /mL working std solns in tray in increasing order of concn, followed by group of samples. Analyze lowest concn std in duplicate, discarding first peak. Precede and follow each group of samples with std ref. curve to correct for possible drift. If drift between first and last set of stds is  $\geq 2$  chart divisions, repeat sample analysis. Prep. std curve by averaging peak hts of first and second set of stds. Plot av. peak ht of stds against mg  $\text{P}_2\text{O}_5$ /mL contained in each std. Read mg  $\text{P}_2\text{O}_5$ /mL for each sample from graph.

%  $\text{P}_2\text{O}_5$  = mg  $\text{P}_2\text{O}_5$ /mL from graph ( $-0.20$ , if spiked)  $\times F \times 100$ , where  $F$  = factor from Table 2.02.

Table 2:02 Standard Dilutions

% $\text{P}_2\text{O}_5$ Expected	Aliquot (mL)		Factor
	Direct Available	Total	
1–7	50 + "spike"	25 + "spike"	1
8–16	no diln	50	0.5
17–34	50	25	2 for direct available
$\geq 35$	25	15	1.667 for total

**Water-Soluble Phosphorus****2.040 Preparation of Solution—Official Final Action**

Place 1 g sample on 9 cm filter and wash with small portions H<sub>2</sub>O until filtrate measures ca 250 mL. Add H<sub>2</sub>O in fine stream directed around entire periphery of filter paper in circular path, ensuring that H<sub>2</sub>O and solids are thoroly mixed with each addn. Let each portion pass thru filter before adding more and use suction if washing would not otherwise be complete within 1 hr. If filtrate is turbid, add 1–2 mL HNO<sub>3</sub>, dil. to 250 mL, and mix.

**2.041 Gravimetric Quinolinium Molybdophosphate Method—Official Final Action**

Pipet aliquot contg  $\leq 25$  mg P<sub>2</sub>O<sub>5</sub> into 500 mL erlenmeyer. Dil., if necessary, to 50 mL, add 10 mL HNO<sub>3</sub> (1+1), and boil gently 10 min. Cool, dil. to 100 mL, and proceed as in 2.028(b).

**2.042 Alkalimetric Quinolinium Molybdophosphate Method—Official Final Action**

Pipet aliquot contg  $\leq 30$  mg P<sub>2</sub>O<sub>5</sub> into 500 mL erlenmeyer. Dil., if necessary, to 50 mL, add 10 mL HNO<sub>3</sub> (1+1), boil gently 10 min, cool, and proceed as in 2.031(a), beginning "... add 20 mL citric acid soln ..."

**2.043 Spectrophotometric Molybdovanadophosphate Method—Official Final Action**

Adjust concn according to 2.024(a) or (b) and proceed as in 2.025.

**Citrate-Insoluble Phosphorus (14)  
Official Final Action****2.044****Reagents**

(a) *Ammonium citrate soln.*—Should have sp gr of 1.09 at 20° and pH of 7.0 as detd potentiometrically.

Dissolve 370 g cryst. citric acid in 1.5 L H<sub>2</sub>O and nearly neutze by adding 345 mL NH<sub>4</sub>OH (28–29% NH<sub>3</sub>). If concn of NH<sub>3</sub> is  $< 28\%$ , add correspondingly larger vol. and dissolve citric acid in correspondingly smaller vol. H<sub>2</sub>O. Cool, and check pH. Adjust with NH<sub>4</sub>OH (1+7) or citric acid soln to pH 7. Dil. soln, if necessary, to sp gr of 1.09 at 20°. (Vol. will be ca 2 L.) Keep in tightly stoppered bottles and check pH from time to time. If pH has changed from 7.0, readjust.

(b) *Other reagents and solns.*—See 2.019, 2.022, or 2.026.

**2.045****Preparation of Extract**

(a) *Acidulated samples, mixed fertilizers, and materials containing water-soluble compounds.*—After removing H<sub>2</sub>O-sol. P<sub>2</sub>O<sub>5</sub>, 2.040, transfer filter and residue, within 1 hr, to 200 or 250 mL flask contg 100 mL NH<sub>4</sub> citrate soln previously heated to 65°. Close flask tightly with smooth rubber stopper, shake vigorously until paper is reduced to pulp, and relieve pressure by removing stopper momentarily. Continuously agitate stoppered flask in const temp. app. at exactly 65°. (Action of app. should be such that dispersion of sample in citrate soln is continually maintained and entire inner surface of flask and stopper is continually bathed with soln.)

Exactly 1 hr after adding filter and residue, remove flask from app. and immediately filter by suction as rapidly as possible thru Whatman No. 5 paper, or equiv., using buchner or ordinary funnel with Pt or other cone. Wash with H<sub>2</sub>O at 65° until vol. filtrate is ca 350 mL, allowing time for thoro draining before adding more H<sub>2</sub>O. If material yields cloudy filtrate, wash with

5% NH<sub>4</sub>NO<sub>3</sub> soln. Prep. citrate-insol. residue for analysis by one of following methods:

(1) Dry paper and contents, transfer to crucible, ignite until all org. matter is destroyed, and digest with 10–15 mL HCl until all phosphate dissolves; or (2) treat wet filter and contents as in 2.020(a), (c), (d), or (e). Dil. soln to 250 mL, or other suitable vol., mix well, and filter thru dry paper.

(b) *Nonacidulated samples.*—Place 1 g sample (ground to pass No. 40 sieve in case of Ca metaphosphate) on dry 9 cm paper. Without previous washing with H<sub>2</sub>O, proceed as in (a). If sample contains much org. matter (bone, fish, etc.), dissolve residue insol. in NH<sub>4</sub> citrate as in 2.020(c), (d), or (e).

**2.046****Determination**

(a) *Gravimetric quinolinium molybdophosphate method (11).*—Treat 1 g sample as in 2.045(a) or (b). Transfer aliquot of citrate-insol. P<sub>2</sub>O<sub>5</sub> contg  $\leq 25$  mg P<sub>2</sub>O<sub>5</sub> and proceed as in 2.028.

(b) *Spectrophotometric molybdovanadophosphate method (15).*—Treat 1 g sample as in 2.045(a) or (b). Adjust concn of citrate-insol. P<sub>2</sub>O<sub>5</sub> soln as in 2.024(a) or (b) and proceed as in 2.025.

(c) *Alkalimetric quinolinium molybdophosphate method (16).*—Treat 1 g sample by 2.045(a) or (b). Transfer aliquot of citrate-insol. P<sub>2</sub>O<sub>5</sub> contg  $\leq 5$  mL concd acid to 500 mL erlenmeyer. Add 20 mL 10% citric acid soln and dil. to 100 mL with H<sub>2</sub>O. Continue as in 2.031(a), beginning "Add 60 mL quimociac reagent, ..."

**2.047 Citrate-Soluble Phosphorus—Official Final Action**

Subtract sum of H<sub>2</sub>O-sol. and citrate-insol. P<sub>2</sub>O<sub>5</sub> from total P<sub>2</sub>O<sub>5</sub> to obtain citrate-sol. P<sub>2</sub>O<sub>5</sub>.

**Available Phosphorus****2.048 Indirect Method—Official Final Action**

Subtract citrate-insol. P<sub>2</sub>O<sub>5</sub> from total P<sub>2</sub>O<sub>5</sub> to obtain available P<sub>2</sub>O<sub>5</sub>.

**Direct Method (17)—Official Final Action****2.049****Reagents**

(Caution: See 51.026, 51.028, 51.030, and Acids, Chap. 51.)

(a) *Nitric-perchloric acid mixture.*—Add 300 mL 70% HClO<sub>4</sub> to 700 mL HNO<sub>3</sub>.

(b) *Ternary acid mixture.*—Add 20 mL H<sub>2</sub>SO<sub>4</sub> to 100 mL HNO<sub>3</sub>, mix, and add 40 mL 70% HClO<sub>4</sub>.

(c) *Modified molybdovanadate reagent.*—Prep. as in 2.022(a) except use 250 mL 70% HClO<sub>4</sub> instead of 450 mL.

**2.050****Preparation of Solution**

(a) *Acidulated samples, mixed fertilizers, and materials containing water-soluble compounds.*—(1) *Without filtration of citrate digest.*—Remove H<sub>2</sub>O-sol. P<sub>2</sub>O<sub>5</sub> as in 2.040, collecting filtrate in 500 mL vol. flask, but do not add HNO<sub>3</sub> to filtrate. Treat H<sub>2</sub>O-insol. residue with NH<sub>4</sub> citrate soln as in 2.045(a). Exactly 1 hr after adding filter and residue, remove flask from app. and transfer contents to flask contg H<sub>2</sub>O-sol. fraction. Cool to room temp. immediately, dil. to vol., mix thoroly, and let stand  $\geq 2$  hr before removing aliquot.

(2) *With filtration of citrate digest.*—If desired, wash by gravity into 500 mL Kohlrausch flask contg 5 mL HNO<sub>3</sub> (1+1), catching filtrate from insol. residue, 2.045(a), in the Kohlrausch flask contg H<sub>2</sub>O-sol. fraction, and wash residue until vol. soln in flask is ca 500 mL. Cool, dil. to 500 mL, and mix.

(b) *Nonacidulated samples*.—Place 1 g sample (ground to pass No. 40 sieve in case of Ca metaphosphate) on dry 9 cm paper. Without previous washing with  $H_2O$ , proceed as in (a)(1) or (2). If (2) is used, wash residue until vol. soln is ca 350 mL. Cool, dil. to 500 mL, and mix.

**2.051 Alkalimetric Quinolinium Molybdophosphate**  
**Method (16)—Official Final Action**

Treat 1 g sample by appropriate modification of 2.050. Transfer aliquot contg  $\leq 30$  mg  $P_2O_5$  and  $\leq 10$  mL  $NH_4$  citrate soln, 2.044(a), to 500 mL erlenmeyer. Dil., if necessary, to 50 mL, add 10 mL  $HNO_3$  (1+1), and boil gently 10 min. Cool, dil. to 100 mL, and continue as in 2.031(a), beginning "Add 60 mL quimociac reagent, . . ."

**2.052 Spectrophotometric Molybdovanadophosphate**  
**Method (18)—Official Final Action**

(Not applicable to materials yielding colored solns or solns contg ions other than orthophosphate which form colored complexes with molybdovanadate. Not recommended for basic slag.)

Prep. std curve as in 2.023, using photometer, 2.021.

Pipet, into 100 mL vol. flasks, 5 mL aliquots std phosphate solns contg 2 and 3.5 mg  $P_2O_5$ /aliquot, 2.022(b), resp., add 2 mL 70%  $HClO_4$ , and develop color as in 2.023. Adjust instrument to zero  $A$  for 2 mg std and det.  $A$  of 3.5 mg std. ( $A$  of latter must be practically identical with corresponding value on std curve.)

Prep. sample as in 2.050.

(a) *Samples containing up to 5%  $P_2O_5$* .—Pipet 10 mL sample soln into 125 mL erlenmeyer, and treat by one of following methods (*Caution: See 51.019, 51.026, and 51.028*):

(1) Add 5 mL 20%  $NaClO_3$  soln and 10 mL  $HNO_3$ - $HClO_4$  mixt., 2.049(a). Boil gently until greenish-yellow color disappears (ca 20 min), cool, and add 2 mL  $HCl$ . After vigorous reaction subsides, evap. to fumes of  $HClO_4$ , and fume 2 min.

(2) Add 5 mL ternary acid mixt., 2.049(b), swirl, boil gently 15 min, and digest at 150–200° until clear white salt or colorless soln remains. Evap. to white fumes and continue heating 5 min.

Cool, add 15 mL  $H_2O$ , and boil 5 min. Transfer to 100 mL vol. flask, dil. to 50 mL, swirl, and cool to room temp. Add 5 mL std phosphate soln contg 2 mg  $P_2O_5$  and 20 mL modified molybdovanadate soln, 2.049(c). Dil. to 100 mL, and continue as in 2.025(a).

(b) *Samples containing more than 5%  $P_2O_5$* .—Dil. soln to such vol. that 5–10 mL aliquot contains 2–5 mg  $P_2O_5$ . Digest as in (a)(1) or (2). Without adding std phosphate soln, continue as in (a).

**2.053 Gravimetric Quinolinium Molybdophosphate**  
**Method (19)—Official Final Action**

(a) *Solns containing no organic phosphorus*.—Prep. sample as in 2.050. Pipet, into 500 mL erlenmeyer, aliquot contg  $\leq 25$  mg  $P_2O_5$  and  $\leq 10$  mL original  $NH_4$  citrate soln. Dil., if necessary, to ca 50 mL, add 10 mL  $HNO_3$  (1+1), and boil gently 10 min. Cool, dil. to 150 mL, and proceed as in 2.028(a) or (b).

(b) *Solns containing organic phosphorus*.—(*Caution: See 51.019, 51.026, and 51.028.*) Select aliquot as in (a). Add 10 mL 20%  $NaClO_3$  and 10 mL  $HNO_3$ - $HClO_4$  mixt., 2.049(a). Boil vigorously until greenish-yellow color disappears (usually ca 30 min), cool, and add 2 mL  $HCl$ . After vigorous reaction subsides, evap. to white fumes, and continue heating 5 min. Cool, and proceed as in 2.028(a) or (b).

## NITROGEN

**2.054 Detection of Nitrates—Official Final Action**

Mix 5 g sample with 25 mL hot  $H_2O$ , and filter. To 1 vol. of this soln add 2 vols  $H_2SO_4$ , free from  $HNO_3$  and oxides of N, and let cool. Add few drops *concd  $FeSO_4$  soln* in such manner that fluids do not mix. If nitrates are present, junction at first shows purple, afterwards brown, or if only minute amt is present, reddish color. To another portion of soln add 1 mL 1%  $NaNO_3$  soln and test as before to det. whether enough  $H_2SO_4$  was added in first test.

## Total Nitrogen

(Provide adequate ventilation in laboratory and do not permit accumulation of exposed Hg.)

**2.055**

**Reagents—Official Final Action**

(a) *Sulfuric acid*.—93–98%  $H_2SO_4$ , N-free.

(b) *Mercuric oxide or metallic mercury*.— $HgO$  or  $Hg$ , reagent grade, N-free.

(c) *Potassium sulfate (or anhydrous sodium sulfate)*.—Reagent grade, N-free.

(d) *Salicylic acid*.—Reagent grade, N-free.

(e) *Sulfide or thiosulfate soln*.—Dissolve 40 g com.  $K_2S$  in 1 L  $H_2O$ . (Soln of 40 g  $Na_2S$  or 80 g  $Na_2S_2O_3 \cdot 5H_2O$  in 1 L may be used.)

(f) *Sodium hydroxide*.—Pellets or soln, nitrate-free. For soln, dissolve ca 450 g solid  $NaOH$  in  $H_2O$ , cool, and dil. to 1 L. (Sp gr of soln should be  $\geq 1.36$ .)

(g) *Zinc granules*.—Reagent grade.

(h) *Zinc dust*.—Impalpable powder.

(i) *Methyl red indicator*.—Dissolve 1 g Me red in 200 mL alcohol.

(j) *Hydrochloric or sulfuric acid std soln*.—0.5N, or 0.1N when amt of N is small. Prep. as in 50.011 or 50.039.

(k) *Sodium hydroxide std soln*.—0.1N (or other specified concn). Prep. as in 50.032–50.034.

Stdze each std soln with primary std, Chap. 50, and check one against the other. Test reagents before use by blank detn with 2 g sugar, which ensures partial reduction of any nitrates present.

*Caution:* Use freshly opened  $H_2SO_4$  or add dry  $P_2O_5$  to avoid hydrolysis of nitriles and cyanates. Ratio of salt to acid (wt:vol.) should be ca 1:1 at end of digestion for proper temp. control. Digestion may be incomplete at lower ratio; N may be lost at higher ratio. Each g fat consumes 10 mL  $H_2SO_4$ , and each g carbohydrate 4 mL  $H_2SO_4$ , during digestion.

**2.056**

**Apparatus—Official Final Action**

(a) *For digestion*.—Use Kjeldahl flasks of hard, moderately thick, well-annealed glass with total capacity ca 500–800 mL. Conduct digestion over heating device adjusted to bring 250 mL  $H_2O$  at 25° to rolling boil in ca 5 min or other time as specified in method. To test heaters, preheat 10 min if gas or 30 min if elec. Add 3–4 boiling chips to prevent superheating.

(b) *For distillation*.—Use 500–800 mL Kjeldahl or other suitable flask, fitted with rubber stopper thru which passes lower end of efficient scrubber bulb or trap to prevent mech. carryover of  $NaOH$  during distn. Connect upper end of bulb tube to condenser tube by rubber tubing. Trap outlet of condenser in such way as to ensure complete absorption of  $NH_3$  distd over into acid in receiver.

### 2.057 Improved Kjeldahl Method for Nitrate-Free Samples (20)—Official Final Action

(Caution: See 51.030 and 51.065.)

Place weighed sample (0.7–2.2 g) in digestion flask. Add 0.7 g HgO or 0.65 g metallic Hg, 15 g powd  $K_2SO_4$  or anhyd.  $Na_2SO_4$ , and 25 mL  $H_2SO_4$ . If sample >2.2 g is used, increase  $H_2SO_4$  by 10 mL for each g sample. Place flask in inclined position and heat gently until frothing ceases (if necessary, add small amt of paraffin to reduce frothing); boil briskly until soln clears and then  $\geq 30$  min longer (2 hr for samples contg org. material).

Cool, add ca 200 mL  $H_2O$ , cool  $<25^\circ$ , add 25 mL of the sulfide or thiosulfate soln, and mix to ppt Hg. Add few Zn granules to prevent bumping, tilt flask, and add layer of NaOH without agitation. (For each 10 mL  $H_2SO_4$  used, or its equiv. in dild  $H_2SO_4$ , add 15 g solid NaOH or enough soln to make contents strongly alk.) (Thiosulfate or sulfide soln may be mixed with the NaOH soln before addn to flask.) Immediately connect flask to distg bulb on condenser, and, with tip of condenser immersed in std acid and 5–7 drops indicator in receiver, rotate flask to mix contents thoroly; then heat until all  $NH_3$  has distd ( $\geq 150$  mL distillate). Remove receiver, wash tip of condenser, and titr. excess std acid in distillate with std NaOH soln. Correct for blank detn on reagents.

$$\% N = [(mL \text{ std acid} \times \text{normality acid}) - (mL \text{ std NaOH} \times \text{normality NaOH})] \times 1.4007 / g \text{ sample}$$

### 2.058 Improved Kjeldahl Method for Nitrate-Containing Samples—Official Final Action

(Not applicable to liqs or to materials with high Cl:NO<sub>3</sub> ratio. Caution: See 51.030 and 51.065.)

Place weighed sample (0.7–2.2 g) in digestion flask. Add 40 mL  $H_2SO_4$  contg 2 g salicylic acid. Shake until thoroly mixed and let stand, with occasional shaking,  $\geq 30$  min; then add (1) 5 g  $Na_2S_2O_3 \cdot 5H_2O$  or (2) 2 g Zn dust (as impalpable powder, not granulated Zn or filings). Shake and let stand 5 min; then heat over low flame until frothing ceases. Turn off heat, add 0.7 g HgO (or 0.65 g metallic Hg) and 15 g powd  $K_2SO_4$  (or anhyd.  $Na_2SO_4$ ), and boil briskly until soln clears, then  $\geq 30$  min longer (2 hr for samples contg org. material).

Proceed as in second par. of 2.057.

### Comprehensive Nitrogen Method (21) Official Final Action

(Applicable to all fertilizer samples.  
Caution: See 51.030 and 51.079.)

#### 2.059

#### Reagents

(a) *Chromium metal*.—100 mesh, low N (Fisher Scientific Co. No. C-318 or Sargent-Welch Scientific Co. No. SC11432 is satisfactory).

(b) *Alundum*.—Boiling stones. 8–14 mesh (Arthur H. Thomas Co. No. 1590–D18, or equiv.).

(c) *Dilute sulfuric acid*.—Slowly add 625 mL  $H_2SO_4$  to 300 mL  $H_2O$ . Dil. to ca 1 L and mix. After cooling, dil. to 1 L with  $H_2O$  and mix. Avoid absorption of  $NH_3$  from air during prepn, particularly if stream of air is used for mixing.

(d) *Sodium thiosulfate or potassium sulfide soln*.—160 g  $Na_2S_2O_3 \cdot 5H_2O/L$  or 80 g  $K_2S/L$ .

For other reagents, see 2.055.

#### 2.060

#### Determination

Place 0.2–2.0 g sample contg  $\leq 60$  mg nitrate N in 500–800 mL Kjeldahl flask and add 1.2 g Cr powder. Add 35 mL  $H_2O$  or, with liqs, amt to make total vol. 35 mL. Let stand 10 min with

occasional gentle swirling to dissolve all nitrate salts. Add 7 mL HCl and let stand  $\geq 30$  sec but  $\leq 10$  min.

Place flask on preheated burner with heat input set at 7.0–7.5 min boil test, 2.056(a). After heating 3.5 min, remove from heat and let cool.

Add 22 g  $K_2SO_4$ , 1.0 g HgO, and few granules Alundum. Add 40 mL dil.  $H_2SO_4$ , (c). (If adequate ventilation is available, 25 mL  $H_2SO_4$  may be added instead of dil.  $H_2SO_4$ . If org. matter which consumes large amt of acid exceeds 1.0 g, add addnl 1.0 mL  $H_2SO_4$  for each 0.1 g org. matter in excess of 1.0 g.)

Place flask on burners set at 5 min boil test. (Pre-heated burners reduce foaming with most samples. Reduce heat input if foam fills  $\geq \frac{2}{3}$  of bulb of flask. Use variable heat input until this phase is past.) Heat at 5 min boil test until dense white fumes of  $H_2SO_4$  clear bulb of flask. Digestion is now complete for samples contg ammoniacal, nitrate, and urea N. For other samples, swirl flask gently and continue digestion 60 min more.

Proceed as in 2.057, second par., substituting 2.059(d) for 2.055(e).

### Modified Comprehensive Nitrogen Method (22) Official First Action

(Applicable to all fertilizer samples)

#### 2.061

#### Reagents

See 2.055(a), (c), (f), (i), (j), (k), 2.059(a), (b), and in addn: *Copper sulfate pentahydrate (or anhydrous copper sulfate)*.—Reagent grade, N-free.

#### 2.062

#### Determination

(Caution: See 51.019 and 51.030.)

Proceed as in 2.060, par. 1 and 2, using 0.2–1.6 g sample. For samples contg orgs other than urea or urea-form, use  $\geq 0.5$  g sample.

Add 15 g  $K_2SO_4$  or 12 g anhyd.  $Na_2SO_4$ , 0.4 g anhyd.  $CuSO_4$  or 0.6 g  $CuSO_4 \cdot 5H_2O$ , and ca 0.8 g Alundum granules. Add 37 mL  $H_2SO_4$  (1+1). (If adequate ventilation is available, 20 mL  $H_2SO_4$  may be added instead of  $H_2SO_4$  (1+1). If org. matter other than urea exceeds 1.0 g, add addnl 1.0 mL  $H_2SO_4$  for each 0.1 g fat or 0.2 g other org. matter in excess of 1.0 g.)

Proceed as in 2.060, par. 4, substituting 75 min for 60 min in last sentence.

Cool flask until it can be handled without gloves, and add ca 250 mL  $H_2O$ . Swirl to dissolve contents, and cool  $<25^\circ$ . Add ca 0.8 g Alundum granules to minimize bumping, tilt flask, and add layer of NaOH without agitation. (For each 10 mL  $H_2SO_4$  used, or its equiv. in  $H_2SO_4$  (1+1), add 15 g solid NaOH or enough soln to make contents strongly alk.) Proceed as in 2.057, par. 2, beginning "Immediately connect flask to distg bulb . . ."

### Raney Powder Method (21) Official Final Action

(Applicable to all fertilizer samples except "nitric phosphates" contg nonsulfate S. Caution: See 51.030 and 51.079.)

#### 2.063

#### Reagents

(a) *Raney catalyst powder No. 2813*.—50% Ni, 50% Al (W. R. Grace & Co., Davison Chemical Division, 10 E Baltimore St, Baltimore, MD 21203). Caution: Raney catalyst powders react slowly in  $H_2O$  or moist air to form alumina; avoid prolonged contact with air or moisture during storage or use.

(b) *Sulfuric acid-potassium sulfate soln*.—Slowly add 200 mL  $H_2SO_4$  to 625 mL  $H_2O$  and mix. Without cooling, add 106.7 g

$K_2SO_4$  and continue stirring until all salt dissolves. Dil. to ca 1 L and mix. Cool, dil. to 1 L with  $H_2O$ , and mix. Avoid absorption of  $NH_3$  from air during prepn particularly if stream of air is used for mixing.

For other reagents, see 2.055.

## 2.064

### Determination

Place 0.2–2.0 g sample contg  $\leq 42$  mg nitrate N in 500–800 mL Kjeldahl flask (800 mL flask is preferred with samples which foam considerably, especially orgs). Add 1.7 g Raney catalyst powder, 3 drops *tributyl citrate*, and 150 mL  $H_2SO_4$ - $K_2SO_4$  soln. If org. matter exceeds 0.6 g, add addnl 2.5 mL of this soln for each 0.1 g org. matter in excess of 0.6 g.

Swirl to mix sample with acid and place flask on cold burner. If burner has been in use, turn off completely  $\geq 10$  min before placing flask on burner. After flask is on burner, set heat input to 5 min boil test. When sample starts boiling, reduce heat to pass 10 min boil test. After 10 min, raise flask to vertical position and add 0.7 g  $HgO$  and 15 g  $K_2SO_4$ . (Contents of Kel-Pak No. 5 (Curtin Matheson Scientific, Inc.) without plastic container may be used.) Replace flask in inclined position and increase heat to 4–5 min boil test. (Reduce heat input if foam fills  $\geq \frac{2}{3}$  of bulb of flask. Use variable heat input until this phase is past.) Heat at 4–5 min boil test until dense white fumes of  $H_2SO_4$  clear bulb of flask. Digestion is now complete for samples contg only ammoniacal, nitrate, and urea N. For other samples, swirl flask gently and continue digestion addnl 30 min.

Proceed as in 2.057, second par. If 800 mL Kjeldahl flasks have been used, add 300 instead of 200 mL  $H_2O$ .

### Ammoniacal Nitrogen

#### 2.065 Magnesium Oxide Method—Official Final Action

(Not applicable in presence of urea)

Place 0.7–3.5 g, according to  $NH_3$  content of sample, in distn flask with ca 200 mL  $H_2O$  and  $\geq 2$  g *carbonate-free MgO*. Connect flask to condenser by Kjeldahl connecting bulb, distil 100 mL liq. into measured amt std acid, 2.055(j), and titr. with std NaOH soln, 2.055(k), using Me red, 2.055(i).

#### 2.066 ★ Formaldehyde Titration Method ★ Official Final Action

(Applicable to  $NH_4NO_3$  and  $(NH_4)_2SO_4$ )

See 2.058, 11th ed.

### Nitrate and Ammoniacal Nitrogen

#### 2.067 ★ Ferrous Sulfate-Zinc-Soda Method ★ Official Final Action

(Not applicable in presence of org. matter, Ca cyanamide, and urea)

See 2.059, 11th ed.

#### 2.068 Devarda Method (23)—Official Final Action

(Not applicable in presence of org. matter, Ca cyanamide, and urea)

Place 0.35 or 0.5 g sample in 600–700 mL flask and add 300 mL  $H_2O$ , 3 g *Devarda alloy* (Cu 50, Al 45, Zn 5), and 5 mL NaOH soln (42% by wt), pouring latter down side of flask so that it does not mix at once with contents. By means of Davisson (J.

Ind. Eng. Chem. 11, 465(1919)) or other suitable scrubbing bulb that will prevent passing over of any spray, connect with condenser, tip of which always extends beneath surface of std acid in receiving flask. Mix contents of distg flask by rotating. Heat slowly at first and then at rate to yield 250 mL distillate in 1 hr. Collect distillate in measured amt std acid, 2.055(j), and titr. with std NaOH soln, 2.055(k), using Me red, 2.055(i).

### Nitrate Nitrogen

#### 2.069 Robertson Method (24)—Official Final Action

(Applicable in presence of Ca cyanamide and urea. Caution: See 51.030 and 51.065.)

(a) Det. total N as in 2.058, 2.060, or 2.064.

(b) Det.  $H_2O$ -insol. N as in 2.072, but use 2.5 g sample. Dil. filtrate to 250 mL.

(c) Place 50 mL portion filtrate in 500 mL Kjeldahl flask and add 2 g  $FeSO_4 \cdot 7H_2O$  and 20 mL  $H_2SO_4$ . (If total N is  $> 5\%$ , use 5 g  $FeSO_4 \cdot 7H_2O$ .) Digest over hot flame until all  $H_2O$  is evapd and white fumes appear, and continue digestion at least 10 min to drive off nitrate N. If severe bumping occurs, add 10–15 glass beads. Add 0.65 g  $Hg$ , or 0.7 g  $HgO$ , and digest until all org. matter is oxidized. Cool, dil., add the  $K_2S$  soln, and complete detn as in 2.057. Before distn, add pinch of mixt. of Zn dust and granular "20-mesh" Zn to each flask to prevent bumping.

Total N (a) –  $H_2O$ -insol. N (b) =  $H_2O$ -sol. N.

$H_2O$ -sol. N – N obtained in (c) = nitrate N.

#### 2.070 Jones Modification of Robertson Method (24) Official Final Action

(Applicable when  $H_2O$ -sol. N need not be detd. Caution: See 51.030 and 51.065.)

Weigh 0.5 g sample into Kjeldahl flask, add 50 mL  $H_2O$ , and rotate gently. Add 2 g  $FeSO_4 \cdot 7H_2O$  and rotate. Add 20 mL  $H_2SO_4$ . Digest over hot flame. When  $H_2O$  evaps and white fumes appear, add 0.65 g  $Hg$  and proceed as in 2.057.

Total N – N thus found = nitrate N.

#### 2.071 ★ Water-Insoluble Nitrogen in Cyanamide (25) ★ Official Final Action

See 2.063, 11th ed.

### Water-Insoluble Nitrogen

(See 2.079(a) and (b) for urea-formaldehyde or mixts contg such compds.)

#### 2.072 Method I—Official Final Action

Place 1 or 1.4 g sample in 50 mL beaker, wet with alcohol, add 20 mL  $H_2O$ , and let stand 15 min, stirring occasionally. Transfer supernate to 11 cm Whatman No. 2 paper in 60° long-stem funnel 60 mm diam., and wash residue 4 or 5 times by decanting with  $H_2O$  at room temp. (20–25°). Finally transfer all residue to filter and complete washing until filtrate measures 250 mL. Det. N in residue as in 2.057.

#### Method II (26)—Official First Action

#### 2.073

#### Apparatus

*Extraction tube*.—Glass, 250 × 10 mm id, 12 mm od, constricted to 3–4 mm at one end.

#### 2.074

#### Determination

Weigh 3.0 g unground mixed sample and place in extn tube contg small glass wool plug. Place addnl glass wool pad on top

★ Surplus method—see inside front cover.

of sample. Connect 250 or 500 mL separator to column with 75 mm piece of rubber tubing. Close stopcock of separator and add 250 mL deionized H<sub>2</sub>O. Open stopcock and let quick rush of H<sub>2</sub>O pass thru column. After initial rush of H<sub>2</sub>O, close stopcock. Adjust flow thru stopcock to ca 2 mL/min. Squeeze rubber connection to bring level of H<sub>2</sub>O ca 25 mm above column bed. System then operates as constant-head feeder.

After H<sub>2</sub>O wash is complete, disconnect column from rubber tubing. Invert column over Kjeldahl flask and force contents into flask with aid of pressure bulb. Wash traces of sample from tube into Kjeldahl flask and wash sample from walls of digestion flask with min. H<sub>2</sub>O. Det. N in residue as in 2.059–2.060 or 2.063–2.064.

### ★ Nitrogen Activity ★

#### 2.075 Removal of Water-Soluble Nitrogen Official Final Action

- (a) *Mixed fertilizers*.—See 2.058, 10th ed.  
(b) *Raw materials*.—See 2.058, 10th ed.

#### 2.076 Water-Insoluble Organic Nitrogen Soluble in Neutral Permanganate Official Final Action

See 2.059, 10th ed.

#### 2.077 Water-Insoluble Organic Nitrogen Distilled from Alkaline Permanganate (27) Official Final Action

See 2.060–2.061, 10th ed.

#### Nitrogen Activity Index (AI) of Urea- Formaldehyde Compounds (28) Official Final Action

(Applicable to urea-formaldehyde compds  
and mixts contg such compds)

#### 2.078 Reagent

*Phosphate buffer soln.*—pH 7.5. Dissolve 14.3 g KH<sub>2</sub>PO<sub>4</sub> and 91.0 g K<sub>2</sub>HPO<sub>4</sub> in H<sub>2</sub>O and dil. to 1 L. Dil. 100 mL of this soln to 1 L.

#### 2.079 Determination

- (a) Crush sample (do not grind) to pass No. 20 sieve.  
(b) Det. cold H<sub>2</sub>O-insol. N (*WIN*) as in 2.072, keeping temp. at 25±2°. Stir at 5 min intervals during 15 min standing.  
(c) Det. hot H<sub>2</sub>O-insol. N (*HWIN*) in phosphate buffer soln as follows: Place accurately weighed sample contg 0.1200 g *WIN* in 200 mL tall-form beaker. Add ca 0.5 g CaCO<sub>3</sub> to mixed fertilizers contg urea-HCHO compds. From supply of boiling buffer soln, add 100 mL from graduate to sample, stir, cover, and immerse *promptly* in boiling H<sub>2</sub>O bath so that liq. in beaker is below H<sub>2</sub>O level in bath. Maintain bath at 98–100°, checked with thermometer, and stir at 10 min intervals. After exactly 30 min, remove beaker from bath and filter promptly thru 15 cm Whatman No. 12 fluted paper. If filtration takes >4 min, discard detn. Repeat detn, stirring in 1 g Celite filter-aid just before removing beaker from bath, and filter.

Wash insol. residue completely onto paper with boiling H<sub>2</sub>O and continue washing until total vol. used is 100 mL. Complete washing before filtrate becomes cloudy or its temp. drops to <60°. Det. total N (*HWIN*) in wet paper and residue as in 2.057, using 35 mL H<sub>2</sub>SO<sub>4</sub> when CaCO<sub>3</sub> has been added.

$$\text{Activity index (AI)} = (\%WIN - \%HWIN) \times 100/\%WIN$$

#### Urea (29)—Official Final Action

#### 2.080

#### Reagent

*Neutral urease soln.*—Use fresh com. 1% urease soln, or dissolve 1 g urease powder in 100 mL H<sub>2</sub>O, or shake 1 g jack bean meal with 100 mL H<sub>2</sub>O 5 min. Transfer 10 mL soln to 250 mL erlenmeyer, dil. with 50 mL H<sub>2</sub>O, and add 4 drops Me purple (available from Fisher Scientific Co.; No. So-I-9). Titr. with 0.1N HCl to reddish purple; then back-titr. to green with 0.1N NaOH. From difference in mL, calc. vol. 0.1N HCl required to neutze remainder of soln (usually ca 2.5 mL/100 mL), add this amount of acid, and shake well.

Verify enzyme activity of urease source periodically. Discard any source which does not produce soln capable of hydrolyzing 0.1 g urea/20 mL soln.

#### 2.081

#### Determination

Weigh 10±0.01 g sample and transfer to 15 cm Whatman No. 12 fluted filter paper. Leach with ca 300 mL H<sub>2</sub>O into 500 mL vol. flask. Add 75–100 mL satd Ba(OH)<sub>2</sub> soln to ppt phosphates. Let settle and test for complete pptn with few drops satd Ba(OH)<sub>2</sub> soln. Add 20 mL 10% Na<sub>2</sub>CO<sub>3</sub> soln to ppt excess Ba and any sol. Ca salts. Let settle and test for complete pptn. Dil. to vol., mix, and filter thru 15 cm Whatman No. 12 fluted paper. Transfer 50 mL aliquot (equiv. to 1 g sample) to 200 or 250 mL erlenmeyer and add 1–2 drops of Me purple. Acidify with 2N HCl and add 2–3 drops excess. Neutze soln with 0.1N NaOH to first change in color of indicator. Add 20 mL neutral urease soln, close flask with rubber stopper, and let stand 1 hr at 20–25°. Cool flask in ice-H<sub>2</sub>O slurry and titr. at once with 0.1N HCl to full purple; then add ca 5 mL excess. Record total vol. added. Back-titr. excess HCl with 0.1N NaOH to neut. end point.

$$\% \text{ Urea} = (\text{mL } 0.1N \text{ HCl} - \text{mL } 0.1N \text{ NaOH}) \times 0.3003.$$

#### Biuret

#### Spectrophotometric Method (30) Official First Action

(Applicable to urea only. Do not use for mixed fertilizers)

#### 2.082

#### Reagents

(a) *Alkaline tartrate soln.*—Dissolve 40 g NaOH in 500 mL H<sub>2</sub>O, cool, add 50 g NaKC<sub>4</sub>H<sub>4</sub>O<sub>6</sub>·4H<sub>2</sub>O, and dil. to 1 L. Let stand 1 day before use.

(b) *Copper sulfate soln.*—Dissolve 15 g CuSO<sub>4</sub>·5H<sub>2</sub>O in CO<sub>2</sub>-free H<sub>2</sub>O and dil. to 1 L.

(c) *Biuret std soln.*—1 mg/mL. Dissolve 100 mg reagent grade biuret in CO<sub>2</sub>-free H<sub>2</sub>O and dil. to 100 mL. Biuret may be purified as follows: Dissolve 10 g in 1 L absolute alcohol and conc. by gentle heating to ca 250 mL. Cool at 5° and filter thru gooch (60% recovery). Repeat crystn and dry final product in vac. oven at 80°.

#### 2.083

#### Preparation of Standard Curve

Transfer series of aliquots, 2–50 mL, of std biuret soln to 100 mL vol. flasks. Adjust vol. to ca 50 mL with CO<sub>2</sub>-free H<sub>2</sub>O, add 1 drop Me red, and neutze with 0.1N H<sub>2</sub>SO<sub>4</sub> to pink color. Add, with swirling, 20 mL alk. tartrate soln and then 20 mL CuSO<sub>4</sub> soln. Dil. to vol., shake 10 sec, and place in H<sub>2</sub>O bath 15 min at 30±5°. Also prep. reagent blank. Det. A of each soln against blank at 555 nm (instrument with 500–570 nm filter is also satisfactory) with 2–4 cm cell. Plot std curve.

★ Surplus method—see inside front cover.

**2.084****Determination**

Continuously stir  $\leq 10$  g sample contg 30–125 mg biuret in 150 mL ca 50° H<sub>2</sub>O 30 min. Filter and wash into 250 mL vol. flask, and dil. to vol. Transfer 50 mL aliquot to 100 mL vol. flask and proceed as in 2.083.

**Atomic Absorption Spectrophotometric Method (31)**  
**Official Final Action**

**2.085****Apparatus and Reagents**

(a) *Atomic absorption spectrophotometer*.—IL Model 353 (Instrumentation Laboratory, Inc., 113 Hartwell Ave, Lexington, MA 02173), or equiv., with Cu hollow cathode lamp.

(b) *Copper sulfate soln.*—Dissolve 15 g CuSO<sub>4</sub>·5H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L.

(c) *Buffer soln.*—pH 13.4. Dissolve 24.6 g KOH and 30 g KCl in H<sub>2</sub>O and dil. to 1 L.

(d) *Starch soln.*—Treat 1 g sol. starch with 10 mL cold H<sub>2</sub>O, triturate to thin paste, and pour gradually into 150 mL boiling H<sub>2</sub>O contg 1 g oxalic acid. Boil until soln clears, cool, and dil. to 200 mL. Prep. fresh weekly.

(e) *Bromocresol purple indicator*.—Dissolve 0.1 g bromocresol purple in 19 mL 0.1N NaOH and dil. to 250 mL with H<sub>2</sub>O.

(f) *Biuret*.—To recrystallize, weigh ca 10 g reagent grade biuret, transfer to 800 mL beaker, add 500 mL H<sub>2</sub>O, and heat on hot plate with occasional stirring until dissolved. Boil until vol. decreases to ca 250 mL. Remove, and let cool gradually to room temp. Filter thru fritted-glass funnel, transfer to evapg dish, and dry 1 hr in 105–110° oven. Remove from oven, place in desiccator, and cool to room temp.

(g) *Biuret std soln.*—0.4 mg/mL. Dissolve 0.4000 g recrystd biuret in warm H<sub>2</sub>O, cool, transfer to 1 L flask, and dil. to vol.

(h) *Copper std solns.*—Dil. aliquots of Cu stock soln, 2.110(b), with H<sub>2</sub>O to obtain  $\geq 4$  std solns within range of detn, 1–4  $\mu$ g Cu/mL final soln.

**2.086****Determination of Calibration Factor**

Transfer aliquots of biuret std soln contg 4, 8, and 12 mg biuret to sep. 100 mL vol. flasks, dil. to ca 30 mL with H<sub>2</sub>O, and add 25 mL alcohol to each. While stirring with mag. stirrer, add 2 mL starch soln, 10 mL CuSO<sub>4</sub> soln, and 20 mL buffer soln. Remove stirring bar, rinse, dil. to vol., mix thoroly, and let stand 10 min. With vac., filter ca 50 mL thru dry 150 mL medium porosity fritted glass funnel into dry flask. Transfer 25 mL aliquots of each filtrate to 250 mL vol. flasks, acidify with 5 mL 1N HCl, and dil. to vol. with H<sub>2</sub>O. Proceed as in 2.109–2.113, using std solns, 2.085(h), to det. complexed Cu in soln by AA spectrophotometry after adding equiv. amts of alcohol, KOH soln, buffer soln, and 1N HCl. Take  $\geq 3$  readings of each soln. From mean value of Cu concn, calc. factor relating mg Cu found to mg biuret added. Redet. daily.

**2.087****Determination**

(a) *In urea*.—Accurately weigh sample contg  $< 10$  mg biuret, dissolve in H<sub>2</sub>O, transfer to 100 mL vol. flask, add 25 mL alcohol, and proceed as in 2.086, beginning "While stirring with mag. stirrer, . . ." From Cu found, calc. biuret concn, using factor.

(b) *In mixed fertilizers*.—Transfer accurately weighed sample contg  $< 40$  mg biuret to 250 mL beaker and add 1 mL H<sub>2</sub>O for each g of sample (5 g max.). Warm, add 65 mL alcohol and 7 drops bromocresol purple, and adjust pH to first blue color (pH 6–7) with 20% KOH. Place on hot plate, heat to bp, cool, and, if pH has changed, make final adjustment to first blue. Vac.-filter thru alcohol-washed paper pulp pad into 100 mL vol. flask. (If filtrate is not clear, improper pH adjustment has been made.

Add HCl and readjust to pH 6–7.) Wash pad and ppt with alcohol and dil. to vol. with alcohol. Transfer 25 mL aliquot to 100 mL vol. flask, and proceed as in 2.086, beginning "While stirring with mag stirrer, . . ." From Cu found, calc. biuret concn, using factor and appropriate diln factors. (Final aliquot can be varied to give Cu concn between 1 and 4  $\mu$ g/mL.)

**POTASSIUM**

**2.088 ★ Lindo-Gladding Method (32) ★**  
**Official Final Action**

Gravimetric detn as K<sub>2</sub>PtCl<sub>6</sub>. See 2.076–2.078, 11th ed.

**2.089 ★ Wet-Digestion Method (33) ★**  
**Official Final Action**

Pptn as K<sub>2</sub>PtCl<sub>6</sub> after digestion with HNO<sub>3</sub> and HCl. See 2.079–2.080, 11th ed.

**2.090 ★ Recovery of Platinum (34) ★**  
**Procedure**

See 2.081–2.083, 11th ed.

**Flame Photometric Method (35)**  
**Official Final Action**

(Caution: See 51.007.)

**2.091****Reagents and Apparatus**

(a) *Ammonium oxalate soln.*—Dissolve 40 g (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> in 1 L H<sub>2</sub>O.

(b) *Methyl red indicator*.—Dissolve 0.2 g Me red in 100 mL alcohol.

(c) *Dilute nitric acid*.—(1+10).

(d) *Anion exchange resin*.—REXYN 203(OH) (Fisher Scientific Co.); Duolite A-7 or Duolite A-41 (Diamond Shamrock, 1100 Superior Ave, Cleveland, OH 44114); Permutit S-100 (Permutit Co., E49 Midland Ave, Paramus, NJ 07652); or equiv.

(e) *Potassium nitrate or potassium chloride*.—Recrystallize reagent grade salt twice from H<sub>2</sub>O and dry 5 hr at 105°.

(f) *Ion exchange column*.—Made from 30 cm length of std wall glass tubing, 2.5 cm od; one end closed by 1-hole No. 4 rubber stopper thru which is inserted 2-way stopcock or glass tubing connected to rubber tubing and compressor clamp. Do not let stopcock tubing protrude above stopper. Choose stopper large enough so that there is no space between stopper vertex and column wall. Alternatively use glass chromatgc tube 300 × 19 mm id with stopcock or valve at bottom to control flow rate (such as SGA Scientific Inc. No. C-4225).

Place glass wool plug in bottom of tube, close valve, and add H<sub>2</sub>O to ht of 10 cm. Transfer portion of resin to 200 mL beaker and suspend in H<sub>2</sub>O. Transfer slurry to column and adjust ht of packed resin to 20 cm, draining excess H<sub>2</sub>O until 2.5 cm head remains. Regenerate resin after 10 successive aliquots have passed thru. For Na, regenerate after 5 aliquots have passed thru.

**2.092****Preparation of Resin**

Place ca 450 g resin in 4 L beaker and add 2 L 5% NaOH. Stir 30 min with elec. stirrer. Let resin settle, and decant NaOH soln. Repeat treatment with 5% NaOH twice, decanting NaOH soln after final treatment. Add 2 L H<sub>2</sub>O to resin, stir few min, let resin settle, and decant wash H<sub>2</sub>O. Repeat 3–4 times. Resin is now in

★ Surplus method—see inside front cover.

free base form. Regenerate to nitrate form by treating 3 times with  $\text{HNO}_3$  (1+19), in same manner as with  $\text{NaOH}$  soln. Wash resin with  $\text{H}_2\text{O}$  until pH of washings is  $\geq 2$  by backwashing in column or by stirring and decanting in large beaker. Store resin under  $\text{H}_2\text{O}$  in stoppered bottle.

**2.093****Preparation of Solution**

(a) *Mixed fertilizers and potassium-magnesium sulfate.*—Weigh 1.5058 g sample into 250 mL vol. flask (500 mL flask if sample contains  $>30\%$   $\text{K}_2\text{O}$ ), add 125 mL  $\text{H}_2\text{O}$  and 50 mL  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  soln, and boil 30 min. Cool, dil. to vol., mix, and pass thru dry filter.

(b) *Potassium chloride and sulfate.*—Dissolve 1.5058 g in  $\text{H}_2\text{O}$  and dil. to 500 mL.

**2.094****Preparation of Standard Curve**

Dissolve 1.2931 g  $\text{KNO}_3$  (or 0.9535 g  $\text{KCl}$ ) in  $\text{H}_2\text{O}$  and dil. to 500 mL (1000 ppm K). Prep. std solns by diln to cover range 0–80 ppm K at intervals  $\leq 10$  ppm, adding appropriate amt  $\text{LiNO}_3$  if internal std instrument is to be used. Prep. std curve of emission against concn, adjusting instrument so that 50 ppm K gives reading near mid-scale. Atomize portions of std solns until readings for series are reproducible.

**2.095****Determination**

(a) *Mixed fertilizers, potassium sulfate, and potassium-magnesium sulfate.*—Transfer 10 mL aliquot of sample soln to 250 mL beaker. Add 1 drop Me red and neutze with  $\text{HNO}_3$  (1+10). Adjust  $\text{H}_2\text{O}$  level in column to top of resin and quant. transfer aliquot to column. Open stopcock to give flow rate of 2 drops/sec, collecting effluent in 250 mL vol. flask. Wash aliquot into resin with 2–3 small portions  $\text{H}_2\text{O}$ . Collect 50–75 mL effluent; then open stopcock and collect addnl 100 mL by pouring  $\text{H}_2\text{O}$  onto column, making certain that  $\text{H}_2\text{O}$  level does not fall below top of resin bed. Dil. to vol. and mix (if internal std instrument is used, add required amt  $\text{LiNO}_3$  before dilg to vol.). Atomize portions of sample several times to obtain reliable av. reading for each soln. Det. ppm K from std curve. (Temp. of std and sample solns must not differ by  $>2^\circ$ .) Calc. %  $\text{K}_2\text{O}$  as follows:

$$\begin{aligned} 0-30\%: & \text{ppm K}/2 = \% \text{K}_2\text{O} \\ >30\%: & \text{ppm K}/1 = \% \text{K}_2\text{O} \end{aligned}$$

(b) *Potassium chloride.*—Proceed as in (a) but omit neutzn and resin treatment.

**2.096****Instrument and Procedure Performance Test**

Weigh 1.5058 g K acid phthalate (primary std;  $\% \text{K}_2\text{O} = 23.0$ ) and transfer to 250 mL vol. flask. Add ca 0.5 g  $(\text{NH}_4)_2\text{HPO}_4$  and proceed as in 2.093(a), beginning "... add 125 mL  $\text{H}_2\text{O}$  ..."

**Table 2:03 Aliquots and factors for potassium determination**

% $\text{K}_2\text{O}$ Expected	Aliquot	Factor
2	no diln	0.0500
3–4	150	0.08333
5–6	100	0.1250
7–8	75	0.1667
9–13	50	0.2500
14–16	40	0.3125
17–20	30	0.4167
21–25	25	0.5000
26–30	20	0.6250
31–43	15	0.8333
44–65	10	1.250

**Automated Flame Photometric Method (36)  
Official Final Action**

(Caution: See 51.007.)

**2.097****Apparatus**

*Automatic analyzer.*—AutoAnalyzer with following modules (available from Technicon Corp.): Sampler II, proportioning pump, flame photometer, range expander, and recorder. Assemble app. as in Fig. 2:07.

**2.098****Reagents**

(a) *Ammonium oxalate soln.*—4%. See 2.091(a).

(b) *Ammonium citrate soln.*—Prep. as in 2.044(a).

(c) *Lithium nitrate soln.*—Dissolve 0.6894 g dried (2 hr at  $105^\circ$ )  $\text{LiNO}_3$  in 1 L  $\text{H}_2\text{O}$ .

(d) *Potassium std solns.*—(1) *Stock soln.*—0.5 mg  $\text{K}_2\text{O}/\text{mL}$ . Dissolve 1.4447 g dried (2 hr at  $105^\circ$ )  $\text{KH}_2\text{PO}_4$  in  $\text{H}_2\text{O}$  and dil. to 1 L. (2) *Working solns.*—35, 38, 41, 44, 47, 50, and 55  $\mu\text{g K}_2\text{O}/\text{mL}$ . Accurately measure 35–55 mL stock soln into 500 mL vol. flasks contg 0.2 g  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  if samples are prep'd by 2.099(a), or 12 mL  $\text{NH}_4$  citrate soln, (b), if by 2.099(b). Dil. to vol. with  $\text{H}_2\text{O}$  and mix. (If std solns contg citrate must be held overnight, add 3–4 drops  $\text{CHCl}_3$ .)

**2.099****Preparation of Samples**

(a) *Ammonium oxalate extraction.*—Weigh 1 g sample into 500 mL vol. flask, add 50 mL 4%  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  and 125 mL  $\text{H}_2\text{O}$ , boil 30 min, and cool. Dil. to vol. with  $\text{H}_2\text{O}$ , mix, and filter or let stand until clear.

(b) *Ammonium citrate extraction from direct available phosphorus extract.*—Prep. as in 2.050. (If solns must be held overnight, add 3–4 drops  $\text{CHCl}_3$ .)

**2.100****Calibration**

Pump 55  $\mu\text{g K}_2\text{O}/\text{mL}$  std working soln continuously thru system. Set range expander to  $1\times$  position and adjust calibration control on flame photometer to read 85%  $T$  on recorder. Pump 35  $\mu\text{g}/\text{mL}$  soln continuously and set range expander to  $2\times$  position. Turn adjustable range positioner or range expander to obtain 23%  $T$  on recorder. Range of 35–55  $\mu\text{g K}_2\text{O}/\text{mL}$  will read ca 20–80%  $T$  on recorder with expander set at  $2\times$ . (Expansion from Model II flame photometers may be  $<20$ –80%  $T$ .)

**2.101****Determination**

Pipet aliquot sample soln as indicated in Table 2:03 into 250 mL vol. flask. Dil. to vol. with  $\text{H}_2\text{O}$  and mix. Place 35–55  $\mu\text{g}/\text{mL}$  working std solns in sampler tray before samples. Place 44  $\mu\text{g}/\text{mL}$  std soln at end of series to check for drift. Read samples and stds at rate of 40/hr (2:1 sample-to-wash ratio). Prep. std curve of emission against  $\text{K}_2\text{O}$  concn and read  $\mu\text{g K}_2\text{O}/\text{mL}$  from graph.

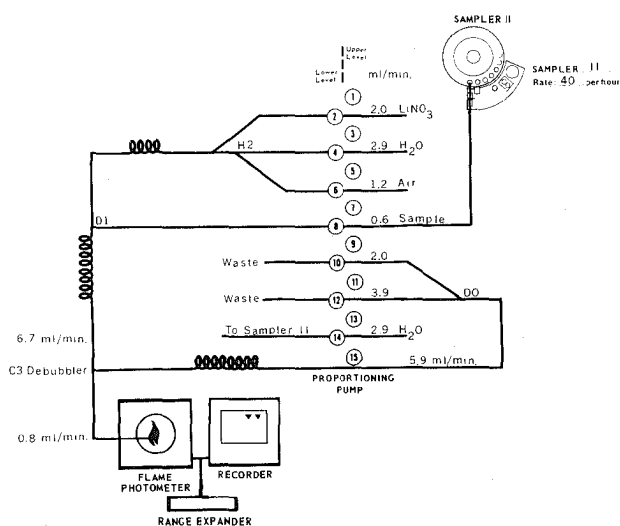

$$\% \text{K}_2\text{O} = (\mu\text{g K}_2\text{O}/\text{mL from graph}) \times \text{factor from Table 2:03.}$$

**Volumetric Sodium Tetraphenylboron Methods****Method I (37)—Official Final Action****2.102****Reagents**

(a) *Formaldehyde soln.*—37%.

(b) *Sodium hydroxide soln.*—20%. Dissolve 20 g  $\text{NaOH}$  in 100 mL  $\text{H}_2\text{O}$ .

(c) *Sodium tetraphenylboron (STPB) soln.*—Approx. 1.2%. Dissolve 12 g  $\text{NaB}(\text{C}_6\text{H}_5)_4$  in ca 800 mL  $\text{H}_2\text{O}$ . Add 20–25 g  $\text{Al}(\text{OH})_3$ .

FIG. 2.07—Flow schematic for  $K_2O$  in fertilizers

stir 5 min, and filter (Whatman No. 42 paper, or equiv.) into 1 L vol. flask. Rinse beaker sparingly with  $H_2O$  and add to filter. Collect entire filtrate, add 2 mL 20% NaOH, dil. to vol. with  $H_2O$ , and mix. Let stand 48 hr and stdze. Adjust so that 1 mL STPB = 1%  $K_2O$ . Store at room temp.

(d) *Benzalkonium chloride (BAC) soln.*—Approx. 0.625%. Dil. 38 mL 17% Zephiran chloride (Winthrop Laboratories; also available at local pharmacies as benzalkonium chloride) to 1 L with  $H_2O$ , mix, and stdze. Cetyltrimethylammonium bromide may be substituted for Zephiran chloride. If other concn is used, adjust vol.

(e) *Clayton Yellow (Titan Yellow; Colour Index No. 19540).*—0.04%. Dissolve 40 mg in 100 mL  $H_2O$ .

## 2.103

### Standardization of Solutions

(a) *BAC soln.*—To 1.00 mL STPB soln in 125 mL erlenmeyer, add 20–25 mL  $H_2O$ , 1 mL 20% NaOH, 2.5 mL HCHO, 1.5 mL 4%  $(NH_4)_2C_2O_4$ , and 6–8 drops indicator, (e). Titr. to pink end point with BAC soln, using 10 mL semimicro buret. Adjust BAC soln so that 2.00 mL = 1.00 mL STPB soln.

(b) *Sodium tetraphenylboron soln.*—Dissolve 2.500 g  $KH_2PO_4$  in  $H_2O$  in 250 mL vol. flask, add 50 mL 4%  $(NH_4)_2C_2O_4$  soln, dil. to vol. with  $H_2O$ , and mix. (It is not necessary to bring to boil.) Transfer 15 mL aliquot (51.92 mg  $K_2O$ , 43.10 mg K) to 100 mL vol. flask; add 2 mL 20% NaOH, 5 mL HCHO, and 43 mL STPB reagent. Dil. to vol. with  $H_2O$ , mix *thoroly*, let stand 5–10 min, and pass thru dry filter. Transfer 50 mL aliquot of filtrate to 125 mL erlenmeyer, add 6–8 drops indicator, (e), and titr. excess reagent with BAC soln. Calc. titer as follows:

$F = 34.61 / (43 \text{ mL} - \text{mL BAC}) = \% K_2O/\text{mL STPB reagent}$ . Factor  $F$  applies to all fertilizers if 2.5 g sample is dild to 250 mL and 15 mL aliquot is taken for analysis. If results are to be expressed as K rather than as  $K_2O$ , substitute 28.73 for 34.61 in calcg  $F$ .

## 2.104

### Determination

Place 2.5 g sample (1.25 g if  $K_2O > 50\%$ ) in 250 mL vol. flask, add 50 mL 4%  $(NH_4)_2C_2O_4$  and 125 mL  $H_2O$ , and boil 30 min. (If org. matter is present, add 2 g  $K$ -free  $C$  before boiling.) Cool, dil. to vol. with  $H_2O$ , mix, and pass thru dry filter or let stand until clear. Transfer 15 mL aliquot sample soln to 100 mL vol. flask and add 2 mL 20% NaOH and 5 mL HCHO. Add 1 mL std STPB soln for each 1%  $K_2O$  expected in sample plus addnl 8 mL

excess to ensure complete pptn. Dil. to vol. with  $H_2O$ , mix *thoroly*, let stand 5–10 min, and filter thru dry paper (Whatman No. 12 or equiv.). Transfer 50 mL filtrate to 125 mL erlenmeyer, add 6–8 drops indicator, (e), and titr. excess reagent with std BAC soln.

$$\% K_2O \text{ in sample} = (\text{mL STPB added} - \text{mL BAC}) \times F,$$

where  $F = \% K_2O/\text{mL STPB reagent}$ . (Multiply by 2 if 1.25 g sample was used.)

### Method II (38)—Official Final Action

(For use with sample prepd for available P detn)

## 2.105

### Reagents

See 2.102(a), (b), (c), (d), and (e).

## 2.106

### Standardization of Solutions

(a) *Benzalkonium chloride.*—In 125 mL erlenmeyer, add 2.5 mL neut.  $NH_4$  citrate soln, 2.044(a), 15–20 mL  $H_2O$ , 4 mL HCHO, and 2.5 mL 20% NaOH soln. Swirl; then add 4.00 mL STPB soln and 6–8 drops indicator, 2.102(e). Titr. to pink end point with BAC soln, using 10 mL semimicro buret. Adjust BAC soln so that 2.00 mL = 1.00 mL STPB soln.

(b) *Sodium tetraphenylboron soln.*—Dissolve 1.4447 g primary std  $KH_2PO_4$  in  $H_2O$  in 500 mL vol. flask, add 100 mL neut.  $NH_4$  citrate soln, 2.044(a), dil. to vol. with  $H_2O$ , and mix. Transfer 25 mL aliquot (25.00 mg  $K_2O$ , 20.75 mg K) to 100 mL vol. flask; add 8 mL HCHO and 5 mL 20% NaOH, swirl, and add 25 mL STPB reagent. Dil. to vol. with  $H_2O$ , mix *thoroly*, let stand 5–10 min, and pass thru dry filter. Transfer 50 mL aliquot of filtrate to 125 mL erlenmeyer, add 6–8 drops indicator, 2.102(e), and titr. excess reagent with BAC soln. Calc. titer as follows:

$$F = 25 \text{ mg } K_2O / (25 \text{ mL STPB} - \text{mL BAC}) \\ = \text{mg } K_2O/\text{mL STPB reagent}.$$

If results are to be expressed as K rather than  $K_2O$ , substitute 20.75 for 25 in calcg  $F$ .

## 2.107

### Preparation of Sample

Prep. as in 2.050.

## 2.108

### Determination

Transfer 25 mL aliquot of sample soln to 100 mL vol. flask. (If org. matter is present, treat 100 mL portion with 1 g  $K$ -free  $C$  and filter before transferring aliquot.) Add 8 mL HCHO *first* and then 5 mL 20% NaOH soln, and wash down sides of flask with  $H_2O$ . Swirl and add 1 mL STPB for each 1.5 mg  $K_2O$  expected in sample aliquot plus addnl 8 mL excess to ensure complete pptn. Dil. to vol. with  $H_2O$ , mix *thoroly*, let stand 5–10 min, and pass thru dry filter (Whatman No. 12, or equiv.). Transfer 50 mL aliquot filtrate to 125 mL erlenmeyer, add 6–8 drops indicator, 2.102(e), and titr. excess reagent with std BAC soln.

$$\% K_2O \text{ in sample} = (\text{mL STPB added} - \text{mL BAC}) \times F \times 2.$$

Calcn applies to all fertilizers if 1 g sample is dild to 500 mL and 25 mL aliquot is taken for analysis.

## OTHER ELEMENTS

### Minor Nutrients by Atomic Absorption Spectrophotometry (39)—Official Final Action

(Caution: See 51.006.)

## 2.109

### Apparatus and Reagent

(a) *Atomic absorption spectrophotometer.*—Several com. models are available. Since each design is somewhat different,

with varying requirements of light source, burner flow rate, and detector sensitivity, only general outline of operating parameters is given in Table 2:04. Operator must become familiar with settings and procedures adapted to his own app. and use table only as guide to concn ranges and flame conditions.

(b) *Disodium EDTA soln.*—2.5%. Dissolve 25 g  $\text{Na}_2\text{H}_2\text{EDTA}$  in 1 L  $\text{H}_2\text{O}$  and adjust to pH 7.0 with 5N NaOH, using pH meter.

Table 2:04 Operating Parameters

Element	Wave-length, Å	Flame	Range $\mu\text{g/mL}$	Remarks
Ca	4227	Rich Air- $\text{C}_2\text{H}_2$	2–20	1% La, 1% HCl
	4227	Rich $\text{N}_2\text{O}-\text{C}_2\text{H}_2$	2–20	Requires special burner
Cu	3247	Air- $\text{C}_2\text{H}_2$	2–20	
Fe	2483	Rich Air- $\text{C}_2\text{H}_2$	2–20	
Mg	2852	Rich Air- $\text{C}_2\text{H}_2$	0.2–2	May need La
Mn	2795	Air- $\text{C}_2\text{H}_2$	2–20	
Zn	2138	Air- $\text{C}_2\text{H}_2$	0.5–5	

## 2.110

### Standard Solutions

(Do not use <2 mL pipets or <25 mL vol. flasks. Automatic diln app. may be used. Prep. std solns in 0–20  $\mu\text{g}$  range fresh daily.)

(a) *Calcium solns.*—(1) *Stock soln.*—25  $\mu\text{g}$  Ca/mL. Dissolve 1.249 g  $\text{CaCO}_3$  in min. amt 3N HCl. Dil. to 1 L. Dil. 50 mL to 1 L. (2) *Working std solns.*—0, 5, 10, 15, and 20  $\mu\text{g}$  Ca/mL contg 1% La. To 25 mL vol. flasks add 0, 5, 10, 15, and 20 mL Ca stock soln. Add 5 mL La stock soln and dil. to 25 mL.

(b) *Copper stock soln.*—1000  $\mu\text{g}$  Cu/mL. Dissolve 1.000 g pure Cu metal in min. amt  $\text{HNO}_3$  and add 5 mL HCl. Evap. almost to dryness and dil. to 1 L with 0.1N HCl.

(c) *Iron stock soln.*—1000  $\mu\text{g}$  Fe/mL. Dissolve 1.000 g pure Fe wire in ca 30 mL 6N HCl with boiling. Dil. to 1 L.

(d) *Lanthanum stock soln.*—50 g La/L. Dissolve 58.65 g  $\text{La}_2\text{O}_3$  (99.99%, Ventron Corp., Alfa Products, 8 Congress St, Beverly, MA 01915, or equiv.) in 250 mL HCl, adding acid slowly. Dil. to 1 L.

(e) *Magnesium stock soln.*—1000  $\mu\text{g}$  Mg/mL. Place 1.000 g pure Mg metal in 50 mL  $\text{H}_2\text{O}$  and slowly add 10 mL HCl. Dil. to 1 L.

(f) *Manganese stock soln.*—1000  $\mu\text{g}$  Mn/mL. Dissolve 1.582 g  $\text{MnO}_2$  in ca 30 mL 6N HCl. Boil to remove Cl and dil. to 1 L.

(g) *Zinc stock soln.*—1000  $\mu\text{g}$  Zn/mL. Dissolve 1.000 g pure Zn metal in ca 10 mL 6N HCl. Dil. to 1 L.

(h) *Other std solns.*—Dil. aliquots of solns (b), (c), (e), (f), and (g) with 0.5N HCl to make  $\geq 4$  std solns of each element within range of detn.

## 2.111

### Preparation of Sample Solutions

(Caution: See 51.019, 51.025, and 51.028.)

(a) *Inorganic materials and mixed fertilizers.*—Dissolve 1.00 g well ground sample in 10 mL HCl in 150 mL beaker. Boil and evap. soln nearly to dryness on hot plate. Do not bake residue. Redissolve residue in 20 mL 2N HCl, boiling gently if necessary. Filter thru fast paper into 100 mL vol. flask, washing paper and residue thoroly with  $\text{H}_2\text{O}$ . Measure absorption of soln directly, or dil. with 0.5N HCl to obtain solns within ranges of instrument. If Ca is to be detd, add enough La stock soln to make final diln 1% La (i.e., 5 mL La to 25 mL flask, 20 mL to 100 mL flask, etc.).

(b) *Fertilizers containing organic matter (tankage, corncobs, cottonseed hulls, etc.).*—Place 1.00 g sample in 150 mL beaker (Pyrex, or equiv.). Char on hot plate and ignite 1 hr at 500° with muffle door propped open to allow free access of air. Break up cake with stirring rod and dissolve in 10 mL HCl as in (a).

(c) *Fertilizers containing fritted trace elements.*—Dissolve

$\leq 1.00$  g well ground sample in 5 mL  $\text{HClO}_4$  and 5 mL HF. Boil and evap. to dense  $\text{HClO}_4$  fumes. Dil. carefully with  $\text{H}_2\text{O}$ , filter, and proceed as in (a). Alternatively, dissolve sample in 10 mL HCl, 5 mL HF, and 10 mL MeOH. Evap. to dryness. Add 5 mL HCl and evap. Repeat HCl addn and evapn. Dissolve residue as in (a). (Normally Pt ware should be used; Pyrex or other glassware may be used if Na, K, Ca, and Fe are not to be detd.)

(d) *For manganese.*—(1) *Acid-soluble, for both  $\text{Mn}^{+2}$  and  $\text{Mn}^{+4}$ .*—See (a), (b), and (c), and 2.139(b). (2) *Acid-soluble, for  $\text{Mn}^{+2}$  only.*—See 2.139(a), 2.140, and 2.141\*. (3) *Water-soluble, for  $\text{Mn}^{+2}$  only.*—See 2.142.

(e) *For iron and zinc.*—(1) *Aqueous extraction.*—Place 1.00 g sample in 250 mL beaker, add 75 mL  $\text{H}_2\text{O}$ , and boil 30 min. Filter into 100 mL vol. flask, washing paper with  $\text{H}_2\text{O}$ . Dil. to vol. and redil. if necessary. (2) *Chelation extraction.*—Place 1.00 g sample in 250 mL beaker, and add 5 cm (2") mag. stirrer bar and 100 mL 2.5% EDTA soln. Stir exactly 5 min, and filter thru Whatman No. 41 paper, or equiv. If filtrate is cloudy, refilter immediately thru fine paper (Whatman No. 5, or equiv.). Redil., if necessary, with 0.5N HCl.

## 2.112

### Determination

(P interferes in Ca and may interfere in Mg detn with air- $\text{C}_2\text{H}_2$  burners. Eliminate interference by adding La stock soln to std and sample solns so that final dilns contain 1% La. P does not interfere with Ca detn when  $\text{N}_2\text{O}-\text{C}_2\text{H}_2$  flame is used.)

Set up instrument as in Table 2:04, or previously established optimum settings for app. to be used. Less sensitive secondary lines (Gatehouse and Willis, Spectrochim. Acta 17, 710(1961)) may be used to reduce necessary diln, if desired. Read  $\geq 4$  std solns within anal. range before and after each group of 6–12 samples. Flush burner with  $\text{H}_2\text{O}$  between samples, and re-establish 0 absorption point each time. Prep. calibration curve from av. of each std before and after sample group. Read concn of samples from plot of absorption against  $\mu\text{g/mL}$ .

## 2.113

### Calculations

$$\% \text{ Element} = (\mu\text{g/mL}) \times (F/\text{sample wt}) \times 10^{-4}$$

$$F = \text{mL original diln} \times \text{mL final diln/mL aliquot, if original 100 mL vol. is dild.}$$

### Acid-Soluble Boron (40)—Official Final Action

## 2.114

### Apparatus

Use high sensitivity glass electrode pH meter for titrn. Use assembly with burets, electrodes, and mech. stirrer, arranged for convenient use with 250 mL beaker. Use ordinary 50 mL burets for the 0.025N NaOH and 0.02N HCl.

## 2.115

### Reagents

(a) *Boric acid std soln.*—Dissolve 1 g  $\text{H}_3\text{BO}_3$  in  $\text{H}_2\text{O}$  and dil. to 1 L. 1 mL = 0.1748 mg B.

(b) *Sodium hydroxide std soln.*— $\text{CO}_2$ -free, ca 0.025N. Stdze as follows: Pipet 25 mL std  $\text{H}_3\text{BO}_3$  soln into 250 mL beaker, add 3.0 g NaCl, acidify to Me red, dil. to 150 mL, boil to expel  $\text{CO}_2$ , cool, and titr. potentiometrically as in 2.116. Det. blank by repeating titrn, substituting 25 mL  $\text{H}_2\text{O}$  for  $\text{H}_3\text{BO}_3$  soln. Calc. B equivalence as follows:

$$\text{mg B/mL} = 4.369/[(\text{mL NaOH soln}) - (\text{mL blank})]$$

Protect from atm.  $\text{CO}_2$  by soda-lime tubes or other suitable means.

(c) *Methyl red indicator.*—Dissolve 0.1 g Me red in 50 mL alcohol, dil. to 100 mL with  $\text{H}_2\text{O}$ , and filter if necessary.

## 2.116

**Determination**

Weigh sample within 1 mg (1.0 g for up to 0.45% B, smaller samples for above that content) and place in 250 mL beaker. Add ca 50 mL H<sub>2</sub>O and 3 mL HCl. Heat to bp and keep hot until carbonates are decomposed. Keep soln hot but do not boil during following phosphate removal:

Add 10%  $Pb(NO_3)_2$  soln, usually 10 mL, or 1 mL for each 1.2% P<sub>2</sub>O<sub>5</sub> if P<sub>2</sub>O<sub>5</sub> content is known to be >12%. Add NaHCO<sub>3</sub>, little at time, until soln approaches neutrality (often observed by formation of white ppt in addn to insol. matter already present). Add few drops Me red and continue adding NaHCO<sub>3</sub> gradually until just alk. to Me red (yellow or very slightly orange). Keep mixt. hot but not boiling (H<sub>2</sub>O bath or steam bath is best) 30 min, adding addnl small amts of NaHCO<sub>3</sub> if needed to keep same indicator color. (If indicator is bleached by nitrate present, add more; if color is obscured by org. matter, use external spot tests to follow neutzn.) After neutzn and heating, 40–50 mL soln should remain.

Filter hot soln into 250 mL beaker and wash solids thoroly with hot H<sub>2</sub>O. Acidify filtrate with few drops HCl and boil briefly to expel most of CO<sub>2</sub>. Neutze hot soln with 0.5N NaOH, and reacidify with 0.5N HCl, using 0.3–0.5 mL excess. Dil. to ca 150 mL and boil gently few min to expel remaining CO<sub>2</sub>. Cool to room temp. in running H<sub>2</sub>O. Roughly neutze mixt., using CO<sub>2</sub>-free 0.5N NaOH, and place beaker in titrn assembly with electrodes and stirrer immersed. Start stirrer and adjust pH to exactly 6.30 by adding 0.025N NaOH or 0.02N HCl as required. (When properly adjusted, pH should be steady; drifting usually is due to incomplete removal of CO<sub>2</sub>.) When reading of pH 6.30 is steady, read 0.025N NaOH buret, add 20 g mannitol or cryst. D-sorbitol, and titr. with 0.025N NaOH to pH 6.30. (Conveniently done with slidewire type instrument by opening pH meter circuit when mannitol is added, leaving scale setting at 6.30, closing circuit again when indicator color shows that end point is being approached, and carefully adding std NaOH soln until galvanometer needle returns to zero. With practice, somewhat slow approach to equilibrium, characteristic of glass electrode, can be anticipated so as not to overrun end point.) When end point is reached, read buret again. Obtain reagent blank by repeating detn with all reagents but without sample.

$$\% B = (\text{mL NaOH soln in detn} - \text{mL blank}) \times (\text{mg B/mL NaOH soln}) / (10 \times \text{g sample})$$

2.117 **Water-Soluble Boron (40)—Official Final Action**

(Not applicable in presence of >5% urea or urea-formaldehyde resins)

Weigh 2.5 g sample into 250 mL beaker. Add 125 mL H<sub>2</sub>O, boil gently ca 10 min, and filter hot thru Whatman No. 40 paper, or equiv., into 400 mL beaker. Wash solids well with 6 portions hot H<sub>2</sub>O and dil. to ≥200 mL with H<sub>2</sub>O. Heat filtrate just to bp. Add 15 mL 10% BaCl<sub>2</sub> soln to ppt sulfates and phosphates, and add powd Ba(OH)<sub>2</sub>, cautiously with stirring, until just alk. to phthln, avoiding large excess. Boil in open beaker ≥60 min to expel NH<sub>3</sub>. (Samples colored by org. matter should be boiled longer.) If necessary, add H<sub>2</sub>O to keep vol. to ≥150 mL. Add and stir 1–2 teaspoonfuls Filter-Cel or other inert filtering aid, and filter with suction thru packed paper pads into 500 mL Pyrex erlenmeyer. Wash ppt 6 times with hot boiled H<sub>2</sub>O. (Avoid too large wash vols which increase vol. in flask to point of dangerous bumping in next step.)

Make filtrate just colorless to phthln with HCl (1+5), add Me red, and make just pink with the acid. Add 5 or 6 boiling stones and stirring rod, cover with watch glass, and boil 5 min to remove CO<sub>2</sub>. Cool in cold H<sub>2</sub>O while covered. Wash cover glass, stirrer, and sides of flask. Titr. to yellow of Me red with std

0.05N NaOH, 50.032–50.036. Add 20 g D-mannitol and 1 mL or more phthln, shake, and wash down sides of flask. Titr. to pink end point. Det. blank in exactly same manner as sample.

1 mL 0.05N NaOH = 0.000540 g B or 0.00477 g Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O. Or, (Titer – blank) × factor = lb Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O/ton (factor = 3.807 for 0.05N NaOH).

2.118 ★ **Carbonate Carbon (41)—Official Final Action** ★

Proceed as in 1.010–1.011, using 2 g sample. Report % CO<sub>2</sub> by wt.

**Water-Soluble Chlorine (42)  
Official Final Action**

## 2.119

**Reagents**

(a) *Silver nitrate std soln.*—Dissolve ca 5 g recrystd AgNO<sub>3</sub> in H<sub>2</sub>O and dil. to 1 L. Stdze against pure, dry NaCl and adjust so that 1 mL soln = 0.001 g Cl.

(b) *Potassium chromate indicator.*—See 50.028(b).

## 2.120

**Determination**

Place 2.5 g sample on 11 cm filter paper and wash with successive portions boiling H<sub>2</sub>O until washings total nearly 250 mL, collecting filtrate in 250 mL vol. flask. Cool, dil. to vol. with H<sub>2</sub>O, and mix well. Pipet 50 mL into 150 mL beaker, add 1 mL K<sub>2</sub>CrO<sub>4</sub> indicator, and titr. with std AgNO<sub>3</sub> soln to permanent red of Ag<sub>2</sub>CrO<sub>4</sub>.

**Acid-Soluble Calcium (43)—Official Final Action**2.121 **Method I**

Weigh 2.5 g sample into 250 mL vol. flask, add 30 mL HNO<sub>3</sub> and 10 mL HCl, and boil 30 min. Cool, dil. to vol., mix, and filter if necessary. Transfer 25 mL aliquot to beaker and dil. to 100 mL. Add 2 drops bromophenol blue, 6.019(f). Add NH<sub>4</sub>OH (1+4) until indicator changes from yellow to green (not blue). If overrun, bring back with HCl (1+4). (This gives pH of 3.5–4.0.) Dil. to 150 mL, bring to bp, and add 30 mL satd hot (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln slowly, stirring constantly. If color changes from green to blue or yellow again, adjust to green with HCl (1+4). If yellow, adjust with NH<sub>4</sub>OH to green. Digest on steam bath 1 hr, or let stand overnight, and cool to room temp. Filter supernate thru quant. paper, gooch, or fritted glass filter, and wash ppt thoroly with NH<sub>4</sub>OH (1+50). Place paper or crucible with ppt in original beaker and add mixt. of 125 mL H<sub>2</sub>O and 5 mL H<sub>2</sub>SO<sub>4</sub>. Heat to ≥70° and titr. with 0.1N KMnO<sub>4</sub> until first slight pink appears. Correct for blank and calc. to Ca.

2.122 **Method II (Atomic Absorption Method)**

See 2.109–2.113.

2.123 ★ **Method III** ★

Place CaC<sub>2</sub>O<sub>4</sub> and filter paper from 2.136 in beaker in which pptn was made and dissolve and titr. as in 2.121.

**Cobalt (44)—Official Final Action**

(Caution: See 51.026, 51.028, and Acids, Chap. 51.)

## 2.124

**Reagents**

(Use H<sub>2</sub>O free of interfering elements. Check by shaking 2 drops 0.01% dithizone in CCl<sub>4</sub> with 10 mL H<sub>2</sub>O. CCl<sub>4</sub> phase should remain green.)

(a) *Ternary acid mixture.*—See 2.049(b).

★ Surplus method—see inside front cover.

(b) *Ammonium hydroxide*.—Use fresh stock. (Reagent becomes contaminated with heavy metals on prolonged storage in glass.)

(c) *Isoamyl acetate*.—Distd.

(d) *2-Nitroso-1-naphthol soln*.—0.05%. Dissolve 0.05 g 2-nitroso-1-naphthol in 8 drops 1*N* NaOH and 1 mL H<sub>2</sub>O. Add 50–60 mL H<sub>2</sub>O and 6.5–7 mL NH<sub>4</sub>OH, and dil. to 100 mL with H<sub>2</sub>O. Divide into 2 ca equal parts and wash each part twice in 100 mL centr. tube with 20 mL isoamyl acetate. Shake 30 sec and centr. after each addn. (It may be necessary to remove part of aq. phase to ensure complete removal of foreign matter at interface.)

(e) *Cobalt std solns*.—(1) *Stock soln*.—200 µg Co/mL. Dissolve 0.0808 g CoCl<sub>2</sub>·6H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL. (2) *Working soln*.—2 µg Co/mL. Dil. 1 mL stock soln to 100 mL with H<sub>2</sub>O.

## 2.125

### Determination

Slowly add 20 mL ternary acid mixt. to 2.00 g pulverized, mixed fertilizer in 150 mL beaker. Cover with watch glass and digest on steam bath overnight. Transfer to hot plate and heat covered until dense white fumes appear. (At this point HNO<sub>3</sub> will have been expelled. Take care not to lose significant amts of HClO<sub>4</sub>.) Dil. sample contg undissolved residue with H<sub>2</sub>O, transfer to 50 mL vol. flask, and dil. to vol. Transfer to 100 mL centr. tube and centr. 5 min at 2000 rpm. Transfer aliquot, contg 2–5 µg Co, to 50 mL g-s centr. tube. Add 10 mL 20% *diammonium citrate soln* and 2 drops phthln. Adjust pH carefully to distinct pink with NH<sub>4</sub>OH (1+1) and add successively 1 mL 10% Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, 2 mL 2-nitroso-1-naphthol soln, and 5 mL isoamyl acetate. (Only isoamyl acetate addn requires high degree of precision.) Shake mixt. 5 min and let sep. Centr., if necessary. Draw off and discard aq. phase thru glass capillary tube attached to vac. Wash isoamyl acetate phase with two 5 mL portions 1*N* NaOH and one 5 mL portion 1*N* HCl. Shake 5 min after each addn, let layers sep., and draw off and discard aq. phase. Centr. 2 min at 1500 rpm and measure *A* or %*T* at 530 nm against isoamyl acetate. Det. Co from calibration curve relating *A* or log %*T* to Co content of std solns contg 0, 2, 4, and 5 µg Co.

### Iron (45)—Official Final Action

(Note: Diphenylamine may be harmful.)

Caution: See 51.079 and 51.084.)

## 2.126

### Reagents

- (a) *Diphenylamine soln*.—Dissolve 1 g in 100 mL H<sub>2</sub>SO<sub>4</sub>.
- (b) *Diphenylamine sulfonate soln*.—Dissolve 0.5 g in H<sub>2</sub>O in 100 mL vol. flask and dil. to vol.
- (c) *Potassium dichromate std solns*.—0.1*N* and 0.01*N*. Prep. 0.1*N* K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> as in 50.024. Prep. 0.01*N* soln by dilg 100 mL 0.1*N* soln to 1 L.
- (d) *Mercuric chloride saturated soln*.—Shake HgCl<sub>2</sub> with H<sub>2</sub>O and let settle.
- (e) *Stannous chloride soln*.—Dissolve 20 g SnCl<sub>2</sub>·2H<sub>2</sub>O in 20 mL HCl, warming gently. Add 20 mL H<sub>2</sub>O and dil. to 100 mL with HCl (1+1). Keep warm until clear; then add few granules Sn. Dispense from dropping bottle.

## 2.127

### Preparation of Sample Solution

- (a) *Suitable for all fertilizers*.—Treat 1 g as in 2.020(e), using 15 mL HClO<sub>4</sub>. Hold ≥1 hr at ca 170° to remove HNO<sub>3</sub> completely. Dil. to 200 mL.
- (b) *Suitable for soluble salts and oxides*.—Dissolve 1 g in 10 mL HCl, warming gently. Dil. to 200 mL.

## 2.128

### Reduction

Heat aliquot of sample soln (100 mL and 50 mL, resp., for

samples contg <0.5 and 0.5–4.0% Fe) to bp. Add few drops diphenylamine sulfonate soln; then SnCl<sub>2</sub> soln dropwise until violet color is discharged and 2 drops excess. (Usually 1–6 drops are required. Larger amt may be used with samples contg large amt of Fe.) If reduction does not occur, discard and proceed as follows with second aliquot:

Add few granules Zn, boil few min, and either filter off excess Zn, washing with hot H<sub>2</sub>O, or let Zn dissolve. Heat to bp and finish reduction with SnCl<sub>2</sub> and diphenylamine sulfonate indicator as before. Add 10 mL HCl (1+1). Adjust vol. to 75–110 mL with H<sub>2</sub>O. Cool rapidly in cold H<sub>2</sub>O. Add 10 mL satd HgCl<sub>2</sub> soln, swirl gently, add 5 mL H<sub>3</sub>PO<sub>4</sub>, and titr. immediately. (Small amt of HgCl must ppt to ensure complete reduction.)

## 2.129

### Titration

Add 1 drop diphenylamine indicator by pipet (no more; excess will interfere with end point if amt of Fe is small). Titr. with 0.01*N* K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> soln. Since end point may be difficult to see with very small amt Fe, approach end point slowly, allowing few sec for color to develop. Titr. to permanent blue (sometimes green with very small amt Fe). For samples contg >4% Fe, use 0.1*N* K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> for titrn. 1 mL 0.1*N* K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> = 0.00558 g Fe; 1 mL 0.01*N* = 0.000558 g Fe.

## 2.130 Atomic Absorption Method

See 2.109–2.113.

### Acid-Soluble Magnesium—Official Final Action

## 2.131 Atomic Absorption Method

See 2.109–2.113.

### EDTA Titration Method (46)

(Applicable to samples contg ≤0.25% Mn or Zn)

## 2.132

### Reagents

- Use reagents 1.022(a), (b), (c), (d), (f) (1 mL = 1 mg Ca, equiv. to 0.6064 mg Mg), (g), (h) (stdzd as in 2.133), and in addn:
  - (a) *Triethanolamine soln*.—(1+1).
  - (b) *Potassium ferrocyanide soln*.—Dissolve 4 g K<sub>4</sub>Fe(CN)<sub>6</sub>·3H<sub>2</sub>O in 100 mL H<sub>2</sub>O.
  - (c) *Ferric ammonium sulfate soln*.—Dissolve 136 g FeNH<sub>4</sub>(SO<sub>4</sub>)<sub>2</sub>·12H<sub>2</sub>O in H<sub>2</sub>O contg 5 mL H<sub>2</sub>SO<sub>4</sub>, and dil. to 1 L. Filter if not clear.

## 2.133

### Standardization

Pipet 10 mL Ca std soln into 300 mL erlenmeyer. Add 100 mL H<sub>2</sub>O, 10 mL KOH-KCN soln, 2 drops triethanolamine soln, 5 drops K<sub>4</sub>Fe(CN)<sub>6</sub> soln, and 15±1 mg calcein indicator. Immediately place flask on mag. or other mech. stirrer in front of daylight fluorescent light and white background. While stirring, titr. with EDTA soln to disappearance of all fluorescent green and until soln remains pink. Titr. ≥3 aliquots. From av., calc. Ca titer in mg/mL EDTA soln. Ca titer × 0.6064 = Mg titer in mg/mL.

## 2.134

### Preparation of Solution

(Caution: See 51.019 and 51.028.)

- (a) *Organic materials*.—Weigh 1 g sample into 250 mL boiling flask or erlenmeyer. Add 5 mL HCl and 10 mL HNO<sub>3</sub>, and boil on hot plate or over low flame until easily oxidized org. matter is destroyed (ca 15 min). Cool, add 5 mL 70–72% HClO<sub>4</sub>, and heat to appearance of copious fumes and momentary cessation of boiling, but not to dryness. Cool, and transfer to 250 mL

beaker with ca 100 mL H<sub>2</sub>O. Continue with pH adjustment, as in 2.135.

(b) *Inorganic materials and mixed fertilizers.*—Weigh 1 g sample into 250 mL beaker. Add 5 mL HCl and 10 mL HNO<sub>3</sub>. Cover with watch glass and heat on asbestos mat on hot plate nearly to dryness (ca 30 min). If soln remains colored from org. residues, cool, add 5 mL HClO<sub>4</sub> (70–72%), and continue heating to copious fumes and momentary cessation of boiling, but not to dryness.

## 2.135

### Determination

Cool prepd soln to room temp. Wash watch glass and inside of beaker to ca 100 mL with H<sub>2</sub>O. Using pH meter with glass electrode and mech. stirring, adjust to ca pH 3 with 30% KOH soln and finally to pH 4.0 with 10% KOH soln. Add FeNH<sub>4</sub>(SO<sub>4</sub>)<sub>2</sub> soln, 5 mL for sample <7% P<sub>2</sub>O<sub>5</sub>, 10 mL for sample 7–15% P<sub>2</sub>O<sub>5</sub>, 15 mL for sample 16–30% P<sub>2</sub>O<sub>5</sub>, and proportionate amts for samples >30% P<sub>2</sub>O<sub>5</sub>. Adjust to pH 5.0 with KOH solns as above, or with HCl (1+4) if pH is >5.0. Cool to room temp. and transfer to 250 mL vol. flask with H<sub>2</sub>O. Dil. to vol. with H<sub>2</sub>O and mix. Let stand until ppt settles. Disturbing ppt as little as possible, filter enough soln for aliquots required for titrn thru dry 11 cm fluted paper, Whatman No. 1, or equiv.

Pipet two equal aliquots contg <15 mg Ca + Mg (usually 25 mL) into two 300 mL erlenmeyers and dil. each to 100 mL with H<sub>2</sub>O. To one (titrn 1 for Ca + Mg) add 5 mL pH 10 buffer soln, 2 mL KCN soln, 2 drops triethanolamine soln, 5 drops K<sub>4</sub>Fe(CN)<sub>6</sub> soln, and 8 drops eriochrome black T indicator. Tit. immediately with EDTA soln, stirring and lighting as in stdzn. Color changes are wine red, purple, dark blue, to clear pure blue end point, becoming green if overtitr.

To second aliquot (titrn 2 for Ca) add 10 mL KOH-KCN soln, 2 drops triethanolamine soln, 5 drops K<sub>4</sub>Fe(CN)<sub>6</sub> soln, and 15±1 mg calcein indicator. Tit. immediately with EDTA soln as in stdzn.

(Titrn 1 – Titrn 2) × Mg titer EDTA × 100/mg sample in aliquot = % Mg.

Titrn 2 × Ca titer EDTA × 10/mg sample in aliquot = % Ca.

## 2.136 ★ Gravimetric Method (47) ★ Official Final Action

Removal of Ca as oxalate, pptn as MgNH<sub>4</sub>PO<sub>4</sub>, and ignition to Mg<sub>2</sub>P<sub>2</sub>O<sub>7</sub>. See 2.123, 11th ed.

## 2.137 ★ Volumetric Method—Official ★ Final Action

Titrn of pptd MgNH<sub>4</sub>PO<sub>4</sub> with acid. See 2.124, 11th ed.

## 2.138 Water-Soluble Magnesium (47) Official Final Action

(a) *In potassium-magnesium sulfate, magnesium sulfate, and kieserite.*—Weigh 1 g sample into 250 mL vol. flask, add 200 mL H<sub>2</sub>O, and boil 30 min. Cool, dil. to vol. with H<sub>2</sub>O, and mix. If detn is to be conducted gravimetrically, 2.136★, or volumetrically, 2.137★, see 2.125, 11th ed.

(b) *In other materials, including mixed fertilizers.*—Weigh 1 g sample into 500 mL vol. flask, add 350 mL H<sub>2</sub>O, and boil 1 hr. Cool, dil. to vol., mix, and filter if necessary. If detn is to be conducted gravimetrically, 2.136★, or volumetrically, 2.137★, see 2.125, 11th ed.

(c) *By EDTA method.*—Transfer aliquot soln prepd as in (a) or (b) to beaker and det. Mg as in 2.135, using HCl or KOH to adjust pH.

★ Surplus method—see inside front cover.

## Acid-Soluble Manganese—Official Final Action

### Atomic Absorption Spectrophotometric Method (48)

#### 2.139

#### Preparation of Sample

(a) *Applicable to Mn<sup>+2</sup> only.*—Prep. sample soln as in 2.140, omitting the 50 mL H<sub>3</sub>PO<sub>4</sub> (1+9). Proceed as in 2.112, using std solns prepd as in 2.110(f) and (h), substituting 0.5N H<sub>2</sub>SO<sub>4</sub> for 0.5N HCl in 2.110(h).

(b) *Applicable to total Mn<sup>+2</sup> and Mn<sup>+4</sup>.*—Prep. sample soln as in 2.111. Proceed as in 2.112, using std solns prepd as in 2.110(f) and (h).

#### 2.140 Colorimetric Method (49)

(Applicable to samples contg Mn<sup>+2</sup> only and with ≤5% Mn)

Place 1 g sample in 200 mL wide-neck vol. flask or 250 mL beaker. Add 10 mL H<sub>2</sub>SO<sub>4</sub> and 30 mL HNO<sub>3</sub>. Heat gently until brown fumes diminish; then boil 30 min. If org. matter is not destroyed, cool, add 5 mL HNO<sub>3</sub>, and boil. Repeat process until no org. matter remains, and boil until white fumes appear. Cool slightly, and add 50 mL H<sub>3</sub>PO<sub>4</sub> (1+9). Boil few min. Cool, dil. to 200 mL in vol. flask, mix, and let stand to allow pptn of CaSO<sub>4</sub>.

Pipet 50 mL clear soln into beaker. Heat nearly to bp. With stirring or swirling, add 0.3 g KIO<sub>4</sub> for each 15 mg Mn present, and hold 30–60 min at 90–100°, or until color development is complete. Cool, and dil. to measured vol. that will provide satisfactory concn for colorimetric measurement by instrument chosen (usually <20 ppm Mn). Compare in colorimeter against std KMnO<sub>4</sub> soln, 7.116, or in spectrophtr at 530 nm. Calc. to Mn.

#### 2.141 ★ Bismuthate Method (50) ★

(Applicable to Mn<sup>+2</sup> only)

See 2.127–2.128, 11th ed.

## Water-Soluble Manganese

### 2.142 Atomic Absorption Spectrophotometric Method (48)—Official Final Action

(Applicable to Mn<sup>+2</sup> only)

Place 1 g sample in 50 mL beaker, wet with alcohol, add 20 mL H<sub>2</sub>O, and let stand 15 min, stirring occasionally. Transfer to 9 cm Whatman No. 5 paper, and wash with small portions H<sub>2</sub>O until filtrate measures ca 230 mL. Let each portion pass thru paper before adding more. Add 3–4 mL H<sub>2</sub>SO<sub>4</sub> to filtrate. Proceed as in 2.112, using std solns prepd as in 2.110(f) and (h), substituting 0.5N H<sub>2</sub>SO<sub>4</sub> for 0.5N HCl in 2.110(h).

## Copper—Official Final Action

### 2.143 ★ Long Volumetric Method (51) ★

See 2.129–2.130, 11th ed.

### Short Volumetric Method (52)

#### 2.144

#### Reagents

(a) *Sodium thiosulfate std soln.*—0.03N. Prep. daily by dilg 0.1N soln, 50.037–50.038. 1 mL 0.03N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 1.906 mg Cu.

(b) *Starch soln.*—Mix ca 1 g sol. starch with enough cold H<sub>2</sub>O to make thin paste, add 100 mL boiling H<sub>2</sub>O, and boil ca 1 min while stirring.

(c) *Bromocresol green indicator.*—Dissolve 0.1 g tetrabromo-m-cresolsulfonphthalein in 1.5 mL 0.1N NaOH, and dil. to 100 mL with H<sub>2</sub>O.

## 2.145

**Determination**

Place 2 g sample in 300 mL erlenmeyer and add 10 mL  $\text{HNO}_3$  and 5 mL  $\text{H}_2\text{SO}_4$ . Digest on hot plate to white fumes. If soln darkens, owing to org. matter, cool slightly, add little more  $\text{HNO}_3$ , and digest again to white fumes, repeating operation if necessary until org. matter appears to be destroyed. Cool, add 50 mL  $\text{H}_2\text{O}$ , boil ca 1 min, and cool to room temp.

Add bromocresol green, then  $\text{NH}_4\text{OH}$  until indicator changes to light green (pH 4). Cool again to room temp., and if indicator changes back to more acid color, add  $\text{NH}_4\text{OH}$  dropwise until indicator becomes light green again, avoiding excess. Add 2 g  $\text{NH}_4\text{HF}_2$  (Toxic. *Caution:* See 51.084), mix well, and let stand ca 5 min. Add 8–10 g KI, mix well, and titr. with std  $\text{Na}_2\text{S}_2\text{O}_3$  soln to light yellow. Add ca 1 mL starch soln and continue titrg slowly until color is nearly same as just before addn of the KI and becomes no darker on standing 20 sec. Report as % Cu.

2.146 **Atomic Absorption Method**

See 2.109–2.113.

**Sodium—Official First Action****Flame Photometric Method (53)—Official First Action**

## 2.147

**Reagents**

See 2.091(a)–(c), and in addn:  
*Sodium chloride.*—Dry 2 hr at 105°.

## 2.148

**Preparation of Solution**

Prep. soln as in 2.093(a), using 2.5 g sample (<4% Na) or 1.25 g (4–20% Na).

## 2.149

**Preparation of Standard Curve**

(a) *Samples containing 1% or more sodium.*—Proceed as in 2.094, using 1.2716 g NaCl, range of diln 0–40 ppm Na, intervals  $\leq 5$  ppm, and full scale for 40 ppm Na.

(b) *Samples containing less than 1% sodium.*—Proceed as in 2.094, using 1.2716 g NaCl, range of diln 0–10 ppm Na, intervals 2 ppm, and full scale for 10 ppm Na.

## 2.150

**Determination**

(*Caution:* See 51.007.)

Transfer 25 mL (<4% Na) or 10 mL (4–20% Na) sample soln to 250 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix (if internal std instrument is used, add required amt  $\text{LiNO}_3$  before dilg to vol.). Atomize portions of sample several times to obtain reliable av. readings for each soln. Det. ppm Na from std curve (a) or (b). Calc. % Na as follows:

$$0\text{--}4\%: \text{ppm Na}/10 = \% \text{ Na}$$

$$4\text{--}20\%: \text{ppm Na}/2 = \% \text{ Na}$$

**Zinc—Official Final Action**2.151 ★ **Gravimetric Method (54) ★**

(For samples contg  $\geq 0.1\%$  Zn)

Digestion with  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ , sepn of interfering sulfides from acid soln with  $\text{H}_2\text{S}$ , pptn of ZnS at pH 3 with  $\text{H}_2\text{S}$ , and ignition to ZnO. See 2.138, 12th ed.

2.152 ★ **Colorimetric Method (55) ★**

(For samples contg <4% Zn)

Digestion with  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ , and detn with dithizone. See 2.139, 12th ed.

**Zincon Ion Exchange Method (56)**

(Clean all glassware with hot chromic acid or  $\text{HNO}_3$  (1+1). Rinse thoroly with  $\text{H}_2\text{O}$ . *Caution:* See 51.023, 51.026, and 51.030.)

## 2.153

**Reagents**

(a) *Anion exchange resin.*—100–200 mesh, strong base, polystyrene alkyl quaternary amine, 7% cross linkage, CGA-540 (J. T. Baker Chemical Co., No. 4602, or equiv.).

(b) *Zincon indicator.*—Dissolve 0.12 g zincon (*o*-[[ $\alpha$ -[(2-hydroxy-5-sulfophenyl)azo]benzylidene]hydrazino]benzoic acid, Na salt) (J. T. Baker Chemical Co., No. X690) in 5 mL 0.3N NaOH and dil. to 100 mL with  $\text{H}_2\text{O}$ . Prep. fresh weekly.

(c) *Hydrochloric acid solns.*—(1) 0.5N.—Dil. 20 mL HCl to 500 mL with  $\text{H}_2\text{O}$ . (2) 0.25N.—Dil. 2 mL HCl to 100 mL with  $\text{H}_2\text{O}$ . (3) 0.005N.—Dil. 2.5 mL HCl to 6 L with  $\text{H}_2\text{O}$ .

(d) *Borate buffer soln.*—pH 9.8. Dissolve 4 g  $\text{H}_3\text{BO}_3$  in 140 mL  $\text{H}_2\text{O}$ . Add 5 mL  $\text{NH}_4\text{OH}$  by pipet and then dropwise to pH 9.8. Check daily.

(e) *Ammonium thiocyanate.*—1M. Dissolve 0.76 g  $\text{NH}_4\text{CNS}$  in 10 mL  $\text{H}_2\text{O}$ .

(f) *Zinc std solns.*—(1) *Stock soln.*—1000 ppm. Dissolve 1.000 g pure Zn metal in small amt HCl- $\text{HNO}_3$  (1+1). Evap. to small vol., add 3 mL HCl, and heat. Dil. to 1 L with  $\text{H}_2\text{O}$ . (2) *Working soln.*—10 ppm. Dil. 10 mL stock soln to 1 L with  $\text{H}_2\text{O}$ .

(g) *Sodium hydroxide soln.*—0.3N. Dissolve ca 1.25 g NaOH in 100 mL  $\text{H}_2\text{O}$ .

## 2.154

**Preparation of Resin Column**

Wash 12 g new resin in 250 mL beaker with  $\text{H}_2\text{O}$  until washings are neut. Introduce resin as slurry into 25 × 2.2 cm chromatgc tube with fritted glass disk and stopcock at bottom. Mark vol. levels on column at 10, 40, and 50 mL above packed resin and on 250 mL separator at 90 mL. (Keep resin wet and store under liq. when not in use.) Connect separator to top of column thru stopper. Attach inverted U-shaped glass dispensing tube to 250 mL vol. flask thru vented stopper or cork and connect with Zn-free plastic tubing to stopcock of column with stopcock grease. See Fig. 2.08.

Mount reservoir (aspirator bottle or carboy) contg  $\geq 1$  L 0.005N HCl high enough to effect backwashing. Attach Zn-free tubing and pinch clamp.

## 2.155

**Flow Calibration**

Use sweep sec hand of watch or stopwatch to establish flow rates. Det. number drops/mL leaving dispensing tube. Remove separator and vol. flask; drain and then backwash resin (see 2.157). Remove reservoir tubing, open stopcock, elute 40 drops from dispensing tube, and measure vol. Use this factor to convert 0.5 mL/min (required in Zn elution, 2.157) to drops/sec.

## 2.156

**Preparation of Sample**

Remove separator and elution tubing from column. Activate resin by draining column and adding 50 mL 0.5N HCl. Drain column to 40 mL mark.

(a) *Samples containing 0.14% or more zinc.*—Dissolve 1.000 g well-ground sample in 10 mL HCl and 5 mL  $\text{HNO}_3$  in 250 mL beaker. Evap. to near dryness on hot plate. (*Caution:* Do not bake.) Redissolve residue in ca 40 mL 0.5N HCl, boiling gently if necessary. Filter thru Whatman No. 41 paper into 100 mL vol. flask. Thoroly wash residue and dil. filtrate to vol. with 0.5N HCl. Drain column to 10 mL mark. Tap column to pack resin. Pipet aliquot contg 0.7–0.8 mg Zn onto column. Elute sample soln at ca 5 sec/drop.

★ Surplus method—see inside front cover.

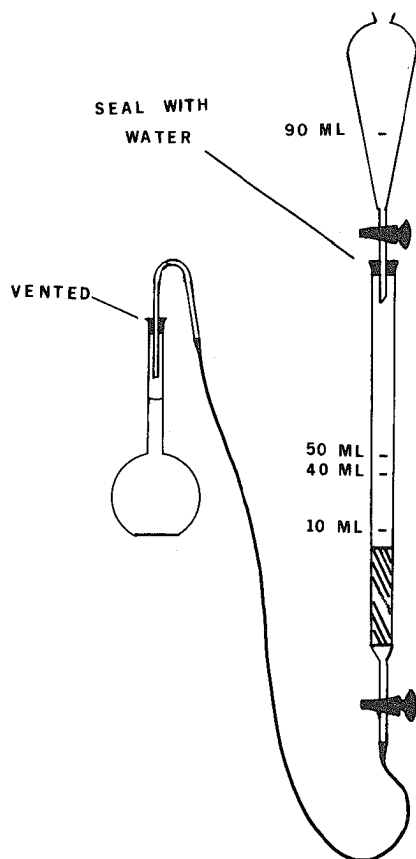

FIG. 2:08—Apparatus for elution of resin column.

(b) *Samples containing less than 0.14% zinc.*—Weigh, to nearest mg, sample contg 0.7–0.8 mg Zn into 250 mL beaker. Digest and filter sample and prep. column as in (a). Tightly attach open separator to column. Close stopcock. Transfer entire sample soln to separator, rinsing with two 10 mL portions 0.5*N* HCl. Open stopcock. Elute sample soln at ca 5 sec/drop. Remove empty separator, rinse twice with 20 mL 0.5*N* HCl, and add rinses to remaining soln in column.

## 2.157

### Elution of Zinc

After sample soln passes thru resin, immediately rinse column with 0.5*N* HCl at ca 1.5 sec/drop until 1 mL eluate gives clear, colorless soln with 1*M*  $\text{NH}_4\text{SCN}$ . If  $\text{Fe}^{+3}$  is present, soln will turn brown. Drain resin and backwash with 0.005*N* HCl from reservoir thru elution tubing, forcing out air bubbles from tubing and column. Simultaneously, tap resin into suspension as it is forced up. Close column stopcock when liq. reaches 50 mL mark on column. Attach dispensing tube to vol. flask. Reopen stopcock, and raise flask until flow just stops. Continue ht adjustment until a drop remains in equilibrium at tip of dispensing tube and neither rises nor falls. Secure flask. Attach open separator with  $\text{H}_2\text{O}$  seal to column and close stopcock. Add 240 mL 0.005*N* HCl to separator and reopen stopcock. Open column stopcock until rate of ca 0.5 mL/min is sustained 10 min. If rate decreases, increase rate slightly until nearly const. Let elution continue overnight. Then, if >90 mL remains in separator, readjust rate as above and continue elution to 90 mL mark. Finally, lower flask, fill to 250 mL mark at convenient rate from dispensing tip, and mix. Detach hose and separator from column, and drain all 3. Reactivate resin, and stopper column as in 2.156.

## 2.158

### Determination

Pipet 20 mL eluate into 50 mL vol. flask contg small piece litmus paper. Make alk. with 0.3*N* NaOH, then just acidic with 0.25*N* HCl. Pipet in 2 mL more acid, 5 mL buffer, and 3 mL zincon soln. Dil. to vol. with  $\text{H}_2\text{O}$ . Similarly prep. 0, 1, 2, and 3 ppm std solns, using 0, 5, 10, and 15 mL std Zn working soln, resp. Using 0 ppm std soln as blank, det. *A* at 620 nm 15–45 min after zincon addn. Plot std curve of ppm against *A*.

$$\% \text{ Zn} = (C \times F)/W,$$

where *C* = ppm from std curve; *W* = g sample; and *F* = 0.0625 for samples contg <0.14% Zn or 6.25/mL aliquot pipetted onto resin for samples contg  $\geq 0.14\%$  Zn.

## 2.159 Atomic Absorption Method

See 2.109–2.113.

### Total Sulfur (57)—Official Final Action

## 2.160

### Reagents

(a) *Barium chloride soln.*—10%. Dissolve 100 g  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$  in 900 mL  $\text{H}_2\text{O}$  and filter thru Whatman No. 42 paper, or equiv. 1 mL = 14 mg S.

(b) *Bromine in carbon tetrachloride.*—10%. Add 10 g Br to 90 g reagent grade  $\text{CCl}_4$ . Stir until homogeneous. Store in g-s bottle. (Caution: See 51.047 and 51.049.)

## 2.161

### Determination

Weigh sample contg 50–150 mg S into 250 mL beaker, and add 20 mL 10% Br in  $\text{CCl}_4$ , (b). Mix by swirling beaker at 5 min intervals during 30 min. Add 15 mL  $\text{HNO}_3$  and mix as before. Evap. to 1–2 mL on warm hot plate. Add 15 mL HCl and 10 mL  $\text{H}_2\text{O}$ . Evap. just to dryness on warm hot plate or steam bath. Add 10 mL HCl and 50 mL  $\text{H}_2\text{O}$ , heat to boiling, boil 5 min, and filter thru Whatman No. 42 paper, or equiv. Wash paper with ten 20 mL portions hot  $\text{H}_2\text{O}$ .

Heat filtrate to boiling. Add 5–6 drops 10%  $\text{BaCl}_2$  soln, (a). After 1 min, add dropwise amt  $\text{BaCl}_2$  soln equiv. to expected S content plus 5 mL excess. Digest at gentle boil 1 hr. Remove from hot plate and let ppt settle 15–20 min. Filter immediately thru previously ignited and weighed gooch. Wash with hot  $\text{H}_2\text{O}$  until 10 mL wash  $\text{H}_2\text{O}$  shows no ppt with 3 mL 1%  $\text{AgNO}_3$ . Dry and ignite at 800° to const wt. Cool in desiccator over  $\text{MgClO}_4$  and weigh.

$$\% \text{ S} = g \text{ BaSO}_4 \times 0.1374 \times 100/g \text{ sample.}$$

## 2.162 Free Sulfur (58)—Official Final Action

(Caution: See 51.011, 51.047, 51.048, and 51.049.)

Ext 1 g sample with  $\text{CS}_2$  in Soxhlet app., letting extn thimble drain  $\geq 12$  times. Transfer ext to 250 mL beaker. Evap.  $\text{CS}_2$  in draft at room temp. Heat in oven 20 min at 60–70°; then cool to room temp. Add 10 mL *satd soln* of Br in  $\text{CCl}_4$ , cover, and let stand ca 30 min, stirring several times. Add 15 mL  $\text{HNO}_3$ , cover, and let stand ca 30 min, stirring several times. Evap. on hot plate to ca 5 mL. Add 20 mL HCl and evap. to ca 5 mL. Add ca 50 mL  $\text{H}_2\text{O}$ , filter, and wash with HCl (1+49). Add 2 drops bromophenol blue, 6.019(f), and then  $\text{NH}_4\text{OH}$  to first color change. Add HCl dropwise until distinctly acid, then 5 drops excess; dil. to 150 mL, heat to bp, and add 10%  $\text{BaCl}_2$  soln, 2.160(a), dropwise until ca 50% excess is present. Cover beaker and digest on steam bath  $\geq 1$  hr. Cool to room temp. and filter thru asbestos on gooch previously ignited at 800° and weighed. Wash 10 times with hot  $\text{H}_2\text{O}$ . Ignite in furnace at 800°  $\geq 20$  min. Cool in desiccator and weigh as  $\text{BaSO}_4$ . Calc. as S as in 2.161.

### 2.163 ★ Acid-Forming or Nonacid-Forming ★ Quality (59)—Official Final Action

Fusion with std amt  $\text{Na}_2\text{CO}_3$  followed by neutzn of melt with excess acid and back-titrn with std NaOH. See 2.141–2.142, 11th ed.

#### PEAT

(Moss, humus, and reed-sedge types)

### 2.164 Sampling (60)—Procedure

Use slotted single or double tube or slotted tube and rod, all with pointed ends and min. 1" diam. for loose materials. Use cutting type core sampler, with plunger, for compressed materials. Pennsylvania State Forage Sampler (NASCO, 901 Janesville Ave, Fort Atkinson, WI 53538) is satisfactory core sampler. Take representative sample from lot or shipment as follows:

(a) *Packaged or baled peats*.—Lay bag or bale horizontally and remove core diagonally from end to end. From lots of 1–10 bags, sample all bags; from lots of  $\geq 11$ , sample 10 bags. Take 1 core from each bag sampled; except for lots of 1–4 bags, take diagonal cores from each bag and addnl cores to total  $\geq 5$  cores.

(b) *Bulk samples*.—Draw  $\geq 10$  cores from different regions.

(c) *Small containers (10 lb or less)*.—Take entire package. Working rapidly to prevent moisture losses, reduce composite sample to  $\leq 500$  g (by wt) or 2 L (by vol.) by mixing on clean plastic or paper and quartering. Place sample in air-tight container.

Sampling by random "grab" procedure is necessary if particle size range is to be detd or if representative sample cannot be taken with core sampler as above.

### 2.165 Preparation of Sample (61)—Official Final Action

Place representative field sample on square rubber sheet, paper, or plastic. Reduce sample to amt required by quartering and place in moisture-proof container. *Work rapidly to prevent moisture losses.*

#### Moisture (61)—Official Final Action

### 2.166 Method I

Mix sample thoroly and place 10–12 g in ignited and weighed (with fitted heavy-duty Al foil cover) Vycor or porcelain evapg dish,  $\geq 75$  mL capacity. Crush soft lumps with spoon or spatula. Cover immediately with Al foil cover and weigh to nearest mg. Dry, uncovered, 16 hr at  $105^\circ$ . Remove from oven, cover tightly, cool, and weigh.

% Moisture (report to nearest 0.1%) = (g as-received sample – g oven-dried sample)  $\times$  100/g as-received sample.

### 2.167 Method II

(Use when pH, N, fiber, etc., are to be detd.)

Mix thoroly and weigh 100–300 g representative sample, 2.165, and spread evenly on large flat pan. Crush soft lumps with spoon or spatula and let come to moisture equilibrium with room air  $\geq 24$  hr. Stir occasionally to maintain max. air exposure of entire sample. When wt is const, calc. loss in wt as % moisture removed by air drying. Grind representative portion air-dried sample 1–2 min in high-speed blender; use for moisture, ash, and N detns.

Mix air-dried, ground sample and weigh, to nearest mg, equiv. of 10 g sample on as-received basis (g air-dried sample equiv.

to 10.0 g as-received sample =  $10.0 - [(10.0 \times \% \text{ moisture removed})/100]$ ). Place weighed sample in ignited and weighed (with fitted heavy duty Al foil cover) Vycor or porcelain evapg dish and proceed as in 2.166.

% Moisture (report to nearest 0.1%) = (10.0 – g oven-dried sample)  $\times$  10.0.

#### Mechanical Analysis for Determination of Particle Size Range (60)—Procedure

### 2.168

#### Apparatus

*Mechanical sieve shaker*.—With 8" diam., Nos. 8 and 20 sieves equipped with cover and bottom pan.

### 2.169

#### Preparation of Sample

Air-dry as in 2.167.

### 2.170

#### Determination

Mix thoroly and place 20.0 g air-dried sample on No. 8 sieve nested on No. 20 sieve. Secure sieves and shake at suitable speed 10 min. Remove and weigh foreign matter, such as sticks, stones, and glass, from No. 8 fraction. Weigh fractions of peat retained on Nos. 8 and 20 sieves and portion collected in bottom pan. Convert fraction and sample wts to as-received basis and calc. in terms of %. (If foreign matter is absent, conversion to as-received basis is not necessary.)

% Foreign matter = fraction removed from No. 8 sieve  $\times$  100;

% Coarse fiber = fraction retained on No. 8 sieve  $\times$  100;

% Medium fiber = fraction retained on No. 20 sieve  $\times$  100;

% Fine = fraction collected in pan  $\times$  100.

If mech. sieve shaker is not available, use hand sieving. Conduct sieving by appropriate lateral and vertical motions accompanied by jarring action. Continue until no appreciable change is noted in sieve fraction.

#### pH (60)—Procedure

### 2.171

#### Apparatus and Reagents

(a) *pH meter*.—Battery-operated or on elec. line with voltage regulator.

(b) *Carbon dioxide-free water*.—See 50.007.

(c) *Acid potassium phthalate buffer soln.*—0.05M. See 50.007(c).

(d) *Phosphate buffer soln.*—0.025M. See 50.007(d).

(e) *Calcium chloride solns (Method II only)*.—(1) *Stock soln.*—1.0M. Dissolve 147 g  $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  in 1 L vol. flask, cool, dil. to vol., and mix. Dil. 15 mL of this soln to 200 mL with  $\text{H}_2\text{O}$  in vol. flask and stdze by titrg 25 mL aliquot dild soln. with std 0.1N  $\text{AgNO}_3$ , 50.029, using 1 mL 5%  $\text{K}_2\text{CrO}_4$  as indicator. (2) *Working soln.*—0.01M (pH 5.0–6.5). Dil. 20 mL stock soln. to 2 L with  $\text{H}_2\text{O}$ .

### 2.172

#### Determination

(a) *Method I (in distilled water)*.—Weigh ca 3.0 g air-dried peat or equiv. amt moist material into 100 mL beaker. Add 50 mL  $\text{H}_2\text{O}$ . (Addnl  $\text{H}_2\text{O}$  may be needed for very fibrous materials such as sphagnum moss peat.) Let soak 30 min, with occasional stirring. Read on pH meter.

(b) *Method II (in 0.01M calcium chloride soln.)*.—Weigh ca 3.0 g air-dried peat or equiv. amt moist material into 100 mL beaker. Add 50 mL 0.01M  $\text{CaCl}_2$ . Let soak 30 min, with occasional stirring. Read on pH meter. Report results as pH in 0.01M  $\text{CaCl}_2$  soln. (pH values in  $\text{CaCl}_2$  soln. are usually ca 0.5–0.8 units lower

★ Surplus method—see inside front cover.

than those in  $H_2O$ . Observed pH in  $CaCl_2$  soln is virtually independent of initial amt salt present in soil, whereas pH readings in  $H_2O$  can be modified by salts such as fertilizer material.)

### 2.173 Ash (61)—Official Final Action

Place uncovered (retain cover for weighing) Vycor or porcelain dish contg dried sample from moisture detn in furnace. Gradually bring to  $550^\circ$  and hold until completely ashed. Cover with retained Al foil cover, cool, and weigh.

% Ash (report to nearest 0.1%) =  $g \text{ ash} \times 100/g \text{ as-received sample taken for moisture detn}$ . (If moisture Method II was used,  $g \text{ as-received sample} = 10.0$ .)

### Sand (60)—Procedure

#### 2.174 Preparation of Sample

Air-dry as in 2.167.

#### 2.175 Determination

(Caution: See 51.056.)

Place 25 g air-dried, ground sample into 125 mL tall-form beaker, or equiv. Nearly fill beaker with  $CHCl_3$ , stir briefly, and let settle ca 1 min. With spoon, discard most floating org. material, decant remaining org. material and  $CHCl_3$ , taking care not to disturb settled portion (sand), and air-dry to remove residual  $CHCl_3$ . (Stirring aids drying.)

When dry, weigh settled portion and calc. as % sand (includes other minerals present such as limestone, etc.).

% Sand =  $(g \text{ air-dried settled residue} \times 100)/g \text{ air-dried sample}$

### 2.176 Organic Matter (61)—Official Final Action

% Org. matter =  $100.0 - (\% \text{ moisture} + \% \text{ ash})$ .

### 2.177 Total Nitrogen (60)—Procedure

Det. N as in 2.057, using well mixed, air-dried, ground sample equiv. to 10.0 g sample on as-received basis.

Det. g air-dried sample equiv. to 10.0 g as-received sample as in 2.167.

### Water Capacity and Volumes (62) Official Final Action

#### 2.178 Apparatus

**Dispensing apparatus.**—2 dispensing burets, 250 mL in 1 mL subdivisions,  $\pm 2$  mL tolerance, pinchcock type; 1-hole No. 6 rubber stopper; straight polyethylene drying tube with serrated rubber tubing fittings, 15 cm long,  $\frac{3}{4}$ " od,  $\frac{5}{8}$ " id (Cenco Instrument Corp. No. 14782-2); and stainless steel screen circle, ca 16 mesh and 28.7 mm diam.

Assemble dispensing app. as follows: Discard serrated rubber tubing fittings from polyethylene drying tube and use tube only. Center stainless steel screen on one end of tube and seal. (Soldering iron is useful.) Adjust length of tube to match convenient graduation of buret; then scallop end without screen to allow for  $H_2O$  drainage, and insert into dispensing buret with screen side up.

#### 2.179 Preparation of Sample

See 2.165.

#### 2.180 Determination

Det. moisture content on sep. sample by 2.166 or 2.167.

Weigh buret fitted with plastic tube and screen. Working rapidly to prevent moisture losses, mix sample thoroly, place on top of No. 4 screen, and shake until sieving is complete. Use only portion that has passed thru sieve for detn. Firmly pack buret with 25 cm (10") of 4 mesh sample as follows: Attach rubber stopper to delivery end of buret. Add ca 20 mL portions, *firmly* tapping 3 times vertically from ht of 15 cm (6") on rubber stopper, for final ht of 25 cm. (This will ensure that ht of final wet vol. is 19–25 cm.) Remove stopper; weigh buret to nearest g. Position buret to use sink as drain. Place  $H_2O$  source (19 L (5 gal.) bottle) equipped with siphon device above level of buret. Connect clamped rubber tubing of siphon device to buret with glass tubing (ca 13 cm (5") long, constricted at one end) inserted into one-hole rubber stopper *fitting tightly* into top of buret. Attach rubber tubing with pinch clamp to delivery end of buret. Open both clamps and pass  $H_2O$  thru sample  $\geq 24$  hr, maintaining water reservoir over sample at all times. (Moss-type samples may float but gradually settle as sample becomes wet.) After initial soaking, regulate  $H_2O$  flow thru column by adjusting screw clamp at delivery end of buret. (In-flow of  $H_2O$  should be ca equal to out-flow; flow of ca 1 drop/sec is suitable.) When sample is *supersatd*, close both clamps and let sample settle in  $H_2O$  ca 5 min. Top surface of sample should be as level as possible.

Raise buret and replace rubber tubing on delivery end of buret with 250 mL dispensing buret filled with  $H_2O$ , using rubber stopper for connection. Connect two burets tightly, *with no air leaks*. Remove siphon device and open outlet clamps of both burets to empty. (Suction created is equiv. to ca 38 cm (15")  $H_2O$ . Check for air leaks to ensure that std suction is exerted on sample. It is important to remove excess  $H_2O$  as described.) Measure ht of wet peat. Ht should be 19–25 cm. Record vol. in mL and weigh buret, plastic tube with screen, and wet peat to nearest g.

Wet sample again as above  $\geq 1$  hr, drain by suction, record vol., and weigh. Repeat until consistent results are obtained.

#### 2.181 Calculations

##### (a) Saturated Volume Weights, g/mL

As-recd =  $g \text{ as-recd sample/mL wet vol.}$

Oven-dried =  $g \text{ dried sample/mL wet vol.}$ , where  $g \text{ dried sample} = g \text{ as-recd sample} \times [(100 - \% \text{ moisture})/100]$ .

Wet =  $g \text{ wet sample/mL wet vol.}$

##### (b) Water-Holding Capacity, %

###### (1) Weight basis:

As-recd =  $[(g \text{ wet sample} - g \text{ as-recd sample}) \times 100]/g \text{ as-recd sample}$

Oven-dried =  $[(g \text{ wet sample} - g \text{ dried sample}) \times 100]/g \text{ dried sample}$

###### (2) Volume basis:

Water vol. =  $[(g \text{ wet sample} - g \text{ dried sample}) \times 100]/(mL \text{ wet vol.} \times 1.0)$

##### (c) Dry Peat Volume, %

Dry peat vol. =  $(g \text{ dried sample} \times 100)/(mL \text{ wet vol.} \times 1.5)$

##### (d) Air Volume, %

Air vol. =  $100 - (\% \text{ water vol.} + \% \text{ dry peat vol.})$

### Alternative Methods (60)

#### Volume—Procedure

#### 2.182 Principle

Method consists of dividing particles of peat from original container by passing them thru 12.7 mm (0.5") sieve and allowing them to fall into vol.-measuring container.

**2.183****Apparatus**

- (a) *Sieve*.—No.  $\frac{1}{2}$ " (12.7 mm).  
 (b) *Measuring box*.—Steel or wood, bound with metal having one of the following sets of inner dimensions: (1)  $\frac{1}{2}$  cu. ft. =  $12 \times 12 \times 12$ " with line scribed 6" from bottom; (2)  $\frac{3}{4}$  cu. ft. =  $12 \times 12 \times 12$ " with line scribed 9" from bottom; (3) 1 cu. ft. =  $12 \times 12 \times 12$ " box, 2 cu. ft. =  $16 \times 16$  base  $\times$  13.5" ht, 5 cu. ft. =  $16 \times 16$  base  $\times$  33.75" ht.

**2.184****Determination**

- (a) *Loose peat*.—Remove material from bag or container, pass it thru  $\frac{1}{2}$ " sieve, and place directly into measuring box. Pour contents from ca 60 cm (2') into measuring box. Det. contents of bag or container only once. Fill corners of measuring box by shaking with rotary motion, 1 rotation/sec for 5 sec, without lifting box from floor or surface. When filled, level off by straightedge. Use ht of box to calc. vol. in cu. ft.  
 (b) *Baled peat*.—Vol. baled material = ht  $\times$  area of base. Correct measurements for outside wrappers. Det. amt loose peat in bale by passing thru  $\frac{1}{2}$ " sieve and measuring amt loose peat, using  $12 \times 12 \times 12$ " box as in (a). Report vol. of peat in cu. ft. Report total vol. of sieved peat from original container.

**Volume Weight, Water-Holding Capacity,  
and Air Capacity of Water-Saturated  
Peat Materials—Procedure**

**2.185****Apparatus**

- (a) *Hollow spray nozzle*.—Monarch F-97-W, nozzle No. 4.6160 (Monarch Mfg. Works Inc., 2501 E Ontario St, Philadelphia, PA 19134), or equiv.  
 (b) *Pipe connection*.—For installation of nozzle on H<sub>2</sub>O faucet in sink.  
 (c) *Containers*.—Approx. 2 L (2 lb coffee cans are suitable) fitted with plastic covers. Replace metal bottom of one with No. 20 Cu screen (test container).  
 (d) *Aluminum pie pans*.—20 cm (8") diam. Drill holes in side walls of pan so that H<sub>2</sub>O depth in pan remains ca 1.3 cm (0.5").

**2.186****Preparation of Sample**

See 2.165.

**2.187****Determination**

Det. moisture content on sep. sample by 2.166 or 2.167.  
 Weigh test container fitted with plastic cover, screen, and circle of filter paper (12.5 cm Whatman No. 4, or equiv.) which is placed on screen. Thoroughly mix equal wts of H<sub>2</sub>O and peat and place in container without pressure to ht of 10 cm (4"); record wt in g. (If peat is dried out, mix 1 part peat with 2 parts H<sub>2</sub>O. If wet, mix 2 parts peat with 1 part H<sub>2</sub>O.)  
 Place test container in Al pan filled with H<sub>2</sub>O in sink  $\geq$  30 cm (12") directly under spray nozzle. Water ca 24 hr as mist to prevent compression of peat. Place cover on container, seal (tape is suitable) to prevent evapn, and let stand in Al pan, maintaining 1.3 cm H<sub>2</sub>O head 2 days. Remove from pan and drain 2 hr with container at 45° angle. Remove seal on cover, and record wt and vol. Vol. can be detd by using container identical to test container not fitted with screen, filling H<sub>2</sub>O to same ht as sample in test container, and transferring to graduate with mL markings.

**2.188****Calculations**

- (a) *Saturated Volume Weights, g/mL*

(1) *As-recd* = g as-recd sample/mL wet vol., where g as-recd

sample = g total sample/2; or g total sample/3 if 2 parts H<sub>2</sub>O used; or (g total sample  $\times$  2)/3 if 2 parts peat used.

(2) *Oven-dried*.—See 2.181.

(3) *Wet*.—See 2.181.

(b) *Water-Holding Capacity, %*

See 2.181.

(c) *Dry Peat Volume, %*

See 2.181.

(d) *Air Volume, %*

See 2.181.

**Cation Exchange Capacity (63)  
Official Final Action**

**AOAC-ASTM Method****2.189****Principle**

Cation exchange capacity is measure of total amt exchangeable cations that can be held by peat, expressed as mequiv./100 g air-dried peat. Peat sample is shaken with 0.5N HCl to remove bases and to sat. sorption complex with H<sup>+</sup>. Excess acid is removed; absorbed H<sup>+</sup> is replaced with Ba<sup>2+</sup>, titrd with 0.1N NaOH, using phthln indicator, and calcd to mequiv./100 g air-dried peat.

**2.190****Reagents**

- (a) *Dilute hydrochloric acid*.—0.5N. Dil. 42 mL HCl to 1 L with H<sub>2</sub>O.  
 (b) *Barium acetate soln*.—0.5N. Dissolve 64 g Ba(OAc)<sub>2</sub> in H<sub>2</sub>O and dil. to 1 L.  
 (c) *Silver nitrate soln*.—1%. Dissolve 1 g AgNO<sub>3</sub> in 100 mL H<sub>2</sub>O.  
 (d) *Sodium hydroxide std soln*.—0.1N. Prep. and stdze as in 50.032–50.035.

**2.191****Preparation of Sample**

See 2.165.

**2.192****Determination**

Thoroughly mix air-dried ground peat sample and place 2.00 g in 300 mL erlenmeyer. Add ca 100 mL 0.5N HCl; stopper flask and shake vigorously periodically during 2 hr (or shake mech. 30 min). Filter thru rapid paper (24 cm fluted, or equiv.) in large powder funnel. Wash with 100 mL portions H<sub>2</sub>O until 10 mL wash shows no ppt with ca 3 mL 1% AgNO<sub>3</sub>. Discard filtrate. Immediately transfer moist peat to 300 mL erlenmeyer, by puncturing apex of paper and forcing moist peat thru funnel stem into erlenmeyer, using spray from wash bottle contg ca 100 mL 0.5N Ba(OAc)<sub>2</sub>. Stopper flask and shake vigorously periodically during 1 hr (or shake mech. 15 min). Filter, and wash with three 100 mL portions H<sub>2</sub>O. Discard peat, and titr. washings with 0.1N NaOH, using 5 drops phthln, to first pink.  
 Calc. mequiv./100 g air-dried peat = (mL  $\times$  normality NaOH  $\times$  100)/g sample.

## 3. Plants

### 3.001 Sampling (1)—Official Final Action

When more than one plant is sampled, include enough plants in sample to ensure that it adequately represents av. composition of entire lot of plants sampled. (This number depends upon variability in composition of the plants.) Det. details of sampling by purpose for which sample is taken.

### 3.002 Preparation of Sample (1)—Official Final Action

(a) *For mineral constituents.*—Thoroughly remove all foreign matter from material, especially adhering soil or sand, but to prevent leaching, avoid excessive washing. Air- or oven-dry as rapidly as possible to prevent decomposition or wt loss by respiration, grind, and store in tightly stoppered bottles. If results are to be expressed on fresh wt basis, record sample wts before and after drying. When Cu, Mn, Zn, Fe, Al, etc. are to be detd, avoid contaminating sample by dust during drying and from grinding and sieving machinery.

(b) *For carbohydrates.*—Thoroughly remove all foreign matter and rapidly grind or chop material into fine pieces. Add weighed sample to hot redistd alcohol to which enough pptd  $\text{CaCO}_3$  has been added to neutze acidity, using enough alcohol so that final concn, allowing for  $\text{H}_2\text{O}$  content of sample, is ca 80%. Heat nearly to bp on steam or  $\text{H}_2\text{O}$  bath 30 min, stirring frequently. (Samples may be stored until needed for analysis.)

### 3.003 Moisture—Official Final Action

See 7.003, 7.006★, or 7.007.

### 3.004 Ash—Official Final Action

See 31.012, 31.013, or 7.009.

### 3.005 Sand and Silica—Official Final Action

Ignite 10–50 g sample in flat-bottom Pt dish in furnace, at 500–550°, until residue is white or nearly so. (Use Pt dishes with caution in ashing plant materials high in Fe; for such materials, use well-glazed porcelain crucibles and include blank detn.) Moisten with 5–10 mL HCl, boil ca 2 min, evap. to dryness, and heat on steam bath 3 hr to render  $\text{SiO}_2$  insol. Moisten residue with 5 mL HCl, boil 2 min, add ca 50 mL  $\text{H}_2\text{O}$ , heat on  $\text{H}_2\text{O}$  bath few min, filter thru hardened paper, and wash thoroly. To this filtrate add filtrate and washings from alkali-sol.  $\text{SiO}_2$  detn (b) and dil. to 200 mL. Designate as *Soln I*.

(a) *Sand.*—Wash residue from filter into Pt dish and boil ca 5 min with ca 20 mL satd  $\text{Na}_2\text{CO}_3$  soln; add few drops 10% NaOH soln, let settle, and decant thru ignited and weighed gooch. Boil residue in dish with another 20 mL portion  $\text{Na}_2\text{CO}_3$  soln and decant as before. Repeat process. Transfer residue to gooch and wash thoroly, first with hot  $\text{H}_2\text{O}$ , then with little HCl (1+4), and finally with hot  $\text{H}_2\text{O}$  until Cl-free. Dry filter and contents, ignite at 500–550°, and weigh as sand. Confirm by microscopic examination.

(b) *Alkali-soluble  $\text{SiO}_2$ .*—Combine alk. filtrate and washings from (a), acidify with HCl, evap. to dryness, add 5 mL HCl, again evap., and dehydrate by heating 2 hr at 110–120°. Moisten residue with 5–10 mL HCl, boil ca 2 min, add ca 50 mL  $\text{H}_2\text{O}$ , and heat on  $\text{H}_2\text{O}$  bath 10–15 min. Filter thru ashless filter or ignited and weighed gooch, wash with hot  $\text{H}_2\text{O}$ , ignite at 500–550°, and weigh as  $\text{SiO}_2$ . Add filtrate to *Soln I*.

## METALS

Calcium, Copper, Iron, Magnesium,  
Manganese, Potassium, and Zinc

### Atomic Absorption Method (2)—Official First Action

#### 3.006

#### Apparatus and Reagents

Deionized  $\text{H}_2\text{O}$  may be used. See 2.109–2.110, and following:

(a) *Potassium stock soln.*—1000  $\mu\text{g}$  K/mL. Dissolve 1.9068 g dried (2 hr at 105°) KCl in  $\text{H}_2\text{O}$  and dil. to 1 L. Use following parameters for Table 2:04: 7665 Å, air- $\text{C}_2\text{H}_2$  flame, and 0.04–2  $\mu\text{g}$ /mL range.

#### 3.007

#### Preparation of Sample

(a) *Dry ashing.*—Accurately weigh 1 g sample, dried and ground as in 3.002(a), into glazed, high-form porcelain crucible. Ash 2 hr at 500°, and let cool. Wet ash with 10 drops  $\text{H}_2\text{O}$ , and carefully add 3–4 mL  $\text{HNO}_3$  (1+1). Evap. excess  $\text{HNO}_3$  on hot plate set at 100–120°. Return crucible to furnace and ash addnl 1 hr at 500°. Cool crucible, dissolve ash in 10 mL HCl (1+1), and transfer quant. to 50 mL vol. flask.

(b) *Wet ashing.*—Accurately weigh 1 g sample, dried and ground as in 3.002(a), into 150 mL Pyrex beaker. Add 10 mL  $\text{HNO}_3$  and let soak thoroly. Add 3 mL 60%  $\text{HClO}_4$  and heat on hot plate, slowly at first, until frothing ceases. (Caution: See 51.019.) Heat until  $\text{HNO}_3$  is almost evapd. If charring occurs, cool, add 10 mL  $\text{HNO}_3$ , and continue heating. Heat to white fumes of  $\text{HClO}_4$ . Cool, add 10 mL HCl (1+1), and transfer quant. to 50 mL vol. flask.

#### 3.008

#### Determination

To soln in 50 mL vol. flask, add 10 mL 5% La soln, and dil. to vol. Let silica settle, decant supernate, and proceed as in 2.112.

#### 3.009

#### Calculations

$$\text{ppm Element} = (\mu\text{g/mL}) \times F/\text{g sample},$$

$$\% \text{ Element} = \text{ppm} \times 10^{-4}.$$

where  $F = (\text{mL original diln} \times \text{mL final diln})/\text{mL aliquot if original 50 mL is dild.}$

### 3.010 Iron and Aluminum (3)—Official Final Action

(Caution: See 51.030.)

Take aliquot of *Soln I*, 3.005, contg enough Fe and Al to form ca 40 mg Fe- and  $\text{AlPO}_4$ . Add few drops  $\text{HNO}_3$ ,  $\text{Br-H}_2\text{O}$ , or  $\text{H}_2\text{O}_2$  to oxidize Fe. If soln does not already contain excess phosphate, add 0.5 g  $(\text{NH}_4)_2\text{HPO}_4$ , stir until dissolved, and dil. to 50 mL with  $\text{H}_2\text{O}$ . Add few drops thymol blue soln, 22.040(e), and then add  $\text{NH}_4\text{OH}$  until soln just turns yellow. Add 0.5 mL HCl and 25 mL 25%  $\text{NH}_4\text{OAc}$  soln, and stir. Let stand at room temp. until ppt settles (ca 1 hr). Filter, and wash 10 times with hot 5%  $\text{NH}_4\text{NO}_3$  soln. Ignite at 500–550° and weigh as  $\text{FePO}_4$  and  $\text{AlPO}_4$ .

Fuse ignited residue in Pt crucible with ca 4 g  $\text{Na}_2\text{CO}_3\text{-K}_2\text{CO}_3$  (1+1) mixt. When fusion is complete, let crucible cool, add 5 mL  $\text{H}_2\text{SO}_4$ , and heat until copious fumes of  $\text{SO}_3$  are evolved. Cool, transfer to flask, add  $\text{H}_2\text{O}$ , and digest until soln is clear. Reduce Fe with Zn, cool, and titr. with 0.1N  $\text{KMnO}_4$ . Correct for blank and calc. as % Fe or %  $\text{Fe}_2\text{O}_3$ . Calc. to  $\text{FePO}_4$  and subtract from total Fe- and  $\text{AlPO}_4$  to obtain  $\text{AlPO}_4$ . Correct for blank and report as  $\text{Al}_2\text{O}_3$ .

### Methods for Iron Only

#### Colorimetric Method (4)—Official Final Action

##### 3.011

##### Reagents

- (a) *Acetic acid*.—2*M*. Dil. 120 g HOAc to 1 L with H<sub>2</sub>O.
- (b) *Ammonium citrate soln*.—1%. Dissolve 1 g NH<sub>4</sub> citrate in H<sub>2</sub>O and dil. to 100 mL.
- (c) *Bromophenol blue indicator*.—0.04%. Grind 0.1 g bromophenol blue in mortar with 3 mL 0.05*N* NaOH, transfer to vol. flask, and dil. to 250 mL with H<sub>2</sub>O.
- (d) *Buffer solns*.—(1) pH 3.5.—Mix 6.4 mL 2*M* NaOAc with 93.6 mL 2*M* HOAc and dil. to 1 L. (2) pH 4.5.—Mix 43 mL 2*M* NaOAc with 57 mL 2*M* HOAc and dil. to 1 L.
- (e) *Hydroquinone soln*.—Dissolve 1 g hydroquinone in 100 mL pH 4.5 buffer, (d)(2). Keep in refrigerator, and discard when any color develops.
- (f) *o-Phenanthroline soln*.—Dissolve 1 g *o*-phenanthroline H<sub>2</sub>O in H<sub>2</sub>O, warming if necessary, and dil. to 400 mL.
- (g) *Sodium acetate soln*.—2*M*. Dissolve 272 g NaOAc·3H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L.
- (h) *Iron std soln*.—1 mg/mL. Dissolve 1 g electrolytic Fe in 50 mL H<sub>2</sub>SO<sub>4</sub> (1+9), warming if necessary to hasten reaction. Cool, and dil. to 1 L with H<sub>2</sub>O.

##### 3.012

##### Preparation of Sample

(Caution: See 51.011, 51.025, and 51.030.)

Use *Soln I*, 3.005, or if *Soln I* is not available, weigh samples of finely ground plant material (1–5 g, depending on Fe content) into porcelain crucibles with smooth inner surfaces, and ash overnight at 500–550° in furnace. Cool, add 5 mL HCl (1+1), and heat on steam bath 15 min to dissolve Fe and to hydrolyze pyrophosphate. Filter into 100 mL vol. flask. Transfer insol. residue to filter and wash 5 times with 3 mL portions hot HCl (1+100), then with hot H<sub>2</sub>O until washings are Cl-free. Ignite paper and any remaining C in Fe-free Pt crucible. Cool, add 2 drops H<sub>2</sub>SO<sub>4</sub> and 1 mL HF, and carefully evap. to SO<sub>3</sub> fumes. Cool, add few drops HCl (1+1), and warm. Filter and wash as before into same vol. flask, dil. to vol., and mix.

##### 3.013

##### Determination

Pipet identical aliquots of *Soln I*, 3.005, or sample soln, 3.012, into 25 mL vol. flask and into test tube or small erlenmeyer. Add 5 drops bromophenol blue indicator to aliquot in test tube, and titr. with 2*M* NaOAc soln until color matches that of equal vol. of pH 3.5 buffer contg same amt of indicator. Add 1 mL hydroquinone soln and 2 mL *o*-phenanthroline soln to aliquot in vol. flask, and adjust pH to 3.5 by adding same vol. NaOAc soln found necessary for aliquot in test tube. If turbidity develops upon adjusting pH of aliquot in test tube, add 1 mL NH<sub>4</sub> citrate soln to vol. flask before adding the NaOAc soln. Dil. to vol., mix, and let stand 1 hr for complete color development, and measure *A* at max., ca 510 nm.

Prep. curve relating *A* to mg Fe in 25 mL by treating series of solns contg amts of Fe that cover usable range of instrument exactly as described for unknowns, detg their respective readings at max. *A*, ca 510 nm, and plotting these against corresponding concns of Fe. H<sub>2</sub>O may be used as ref., and blanks detd to correct for amt Fe in reagents used, or blank soln itself may be made basis of comparison.

#### 3.014 Titrimetric Method (5)—Official Final Action

Take appropriate aliquot of *Soln I* or of soln prepd as in 3.012, and oxidize Fe by adding soln of KMnO<sub>4</sub> (1+1000) dropwise until very faint permanganate color persists. Add 5 mL 10% NH<sub>4</sub>SCN

and titr. with dil. TiCl<sub>3</sub> soln until red color disappears. (To prep. appropriate TiCl<sub>3</sub> soln, boil 5–10 mL 20% TiCl<sub>3</sub> with 50 mL HCl few min, cool, and dil. to 1 L. Stdze against std Fe soln, keep in dark in well-filled container, and restdze each time it is used, or every few hr when many detns are being made. Discard when decomposition is indicated by loss of color and increased titer against std.)

### Calcium—Official Final Action

#### 3.015 Macro Method (6)

Transfer aliquot of *Soln I*, 3.005, to 200 mL beaker, add H<sub>2</sub>O if necessary to vol. of 50 mL, heat to bp, and add 10 mL satd (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln and drop Me red, 2.055(i). Almost neutze with NH<sub>4</sub>OH and boil until ppt is coarsely granular. Cool, add NH<sub>4</sub>OH (1+4) until color is faint pink (pH 5.0), and let stand ≥4 hr. Filter, and wash with H<sub>2</sub>O at room temp. until filtrate is oxalate-free. (Reserve filtrate and washings for Mg detn, 3.017.)

Break point of filter with Pt wire, and wash ppt into beaker in which Ca was pptd, using stream of hot H<sub>2</sub>O. Add ca 10 mL H<sub>2</sub>SO<sub>4</sub> (1+4), heat to ca 90°, add ca 50 mL hot H<sub>2</sub>O, and titr. with 0.05*N* KMnO<sub>4</sub>. Finally add filter paper to soln and complete titrn.

#### 3.016 Micro Method (7)

Weigh 2 g sample into small crucible and ignite in furnace at 500–550°. Dissolve ash in HCl (1+4) and transfer to 100 mL beaker. Add 5 mL HCl and evap. to dryness on steam bath to dehydrate SiO<sub>2</sub>. Moisten residue with 5 mL HCl, add ca 50 mL H<sub>2</sub>O, heat few min on steam bath, transfer to 100 mL vol. flask, cool quickly to room temp., dil. to vol., shake, and filter, discarding first portion of filtrate.

Pipet 15 mL aliquot into conical-tip centr. tube contg 2 mL satd (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln and 2 drops Me red, 2.055(i). Add 2 mL HOAc (1+4), rotating tube to mix contents thoroly. Add NH<sub>4</sub>OH (1+4), while intermittently rotating tube, until soln is faintly alk.; then add few drops of the HOAc until color is faint pink (pH 5.0). (It is important at this point to rotate tube so that last bit of liq. in conical tip has required color.) Let stand ≥4 hr; then centr. 15 min. (Ppt should be in firm lump in tip of tube.) Remove supernate, using suction device, Fig. 3:01, taking care not to disturb ppt. Wash ppt by adding 2 mL NH<sub>4</sub>OH (1+49), rotating tube to break up ppt. (It may be necessary to jar tube sharply.) Centr. 10 min, again remove supernate, and wash with reagent as before. Repeat washing of ppt 3 times.

After removing last supernate, add 2 mL H<sub>2</sub>SO<sub>4</sub> (1+4) to tube, break up ppt as before, heat on steam bath to 80–90°, and titr.

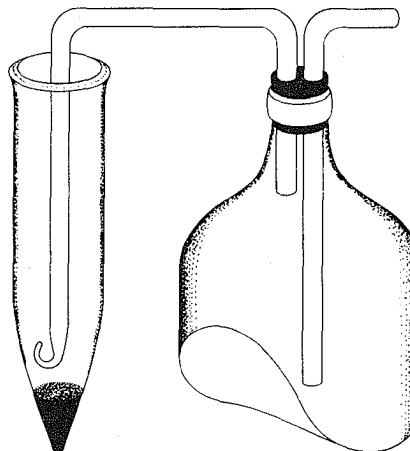

FIG. 3:01—Suction device used in micro method for determining calcium

in tube with 0.02N  $\text{KMnO}_4$ , rotating liq. during titrn to attain proper end point. If tube cools to  $<60^\circ$  during titrn, as indicated by slow reduction of  $\text{KMnO}_4$ , reheat in steam bath few min and complete titrn. Perform blank on identical vol.  $\text{H}_2\text{SO}_4$  in similar tube heated to same temp. to det. vol.  $\text{KMnO}_4$  soln necessary to give end point color. Subtract this value from buret reading. 1 mL 0.02N  $\text{KMnO}_4 = 0.000400$  g Ca. Report as % Ca.

### 3.017 Magnesium (8)—Official Final Action

(Caution: See 51.026.)

To combined filtrate and washings from Ca detn, 3.015, add 30 mL  $\text{HNO}_3$  and evap. to dryness to decompose  $\text{NH}_4$  salts. Take up with 5 mL  $\text{HCl}$  and dil. to ca 100 mL with  $\text{H}_2\text{O}$ . Add 5 mL 10% Na citrate soln and 10 mL 10%  $(\text{NH}_4)_2\text{HPO}_4$  soln, or enough to ppt all the Mg. Add  $\text{NH}_4\text{OH}$  (1+4) with const stirring (using policeman) until soln is faintly alk. and ppt forms; then add 25 mL  $\text{NH}_4\text{OH}$ , stir vigorously until ppt is granular, and keep in cool place overnight. Filter, and wash  $\text{Cl}$ -free with cold  $\text{NH}_4\text{OH}$  (1+10). Incinerate in furnace at  $500\text{--}550^\circ$  until all C is oxidized, then at  $900\text{--}950^\circ$  ca 4 hr to form  $\text{Mg}_2\text{P}_2\text{O}_7$ . Cool, and weigh as  $\text{Mg}_2\text{P}_2\text{O}_7$ . (If sample is excessively high in Mn, dissolve residue in  $\text{HNO}_3$ , det. Mn as in 3.018, and correct  $\text{Mg}_2\text{P}_2\text{O}_7$  for  $\text{Mn}_2\text{P}_2\text{O}_7$ .) Report as % Mg.

### 3.018 Manganese (9)—Official Final Action

To aliquot of Soln I, 3.005, contg 0.2–0.5 g ash, add 15 mL  $\text{H}_2\text{SO}_4$  and evap. to ca 30 mL. Add 5–10 mL  $\text{HNO}_3$  and continue evap. (Do not evap. until dense fumes appear, because  $\text{Fe}_2(\text{SO}_4)_3$  then dissolves with difficulty.  $\text{HNO}_3$  may be present, but not  $\text{HCl}$ .) Add  $\text{H}_2\text{O}$ , little at time, heat until Fe salts dissolve, and dil. to ca 150 mL. Add 0.3 g  $\text{KIO}_4$ , or its equiv. in  $\text{HIO}_4$ , in small portions, boil few min or until color of  $\text{KMnO}_4$  shows no further increase in intensity, and let cool.

Prep. std as follows: To vol.  $\text{H}_2\text{O}$  equal to sample add 15 mL  $\text{H}_2\text{SO}_4$  and enough pure  $\text{Fe}(\text{NO}_3)_3$ , free from Mn, to equal approx. amt of Fe in sample. Add measured vol. 0.1N  $\text{KMnO}_4$  until color is slightly darker than sample, then add 0.3 g  $\text{KIO}_4$ , and boil few min. When cool, transfer sample and std to 250 mL vol. flasks and dil. to vol. with  $\text{H}_2\text{O}$ . (If color is weak, it may be necessary to dil. to  $<250$  mL.) Measure  $A$  with photometer or spectrophtr set at max., ca 530 nm. Report as % Mn.

### 3.019 ★ Potassium and Sodium ★ Official Final Action

Ignition, removal of Fe, Al, and P with  $\text{NH}_4\text{OH}$ , sulfate as  $\text{BaSO}_4$ , Ca as oxalate,  $\text{NH}_3$  by ignition, and final weighing as  $\text{NaCl} + \text{KCl}$ . See 3.015, 11th ed.

#### Potassium and/or Sodium Flame Photometric Method (10) Official Final Action

#### 3.020

#### Reagents

(a) Potassium stock soln.—1000 ppm K. Dissolve 1.907 g dry  $\text{KCl}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(b) Sodium stock soln.—1000 ppm Na. Dissolve 2.542 g dry  $\text{NaCl}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(c) Lithium stock soln.—1000 ppm Li. Dissolve 6.108 g  $\text{LiCl}$  in  $\text{H}_2\text{O}$  and dil. to 1 L. (Needed only if internal std method of evaluation is to be used.)

(d) Ammonium oxalate stock soln.—0.24N. Dissolve 17.0 g  $(\text{NH}_4)_2\text{C}_2\text{O}_4 \cdot \text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

★ Surplus method—see inside front cover.

(e) Extracting solns.—(1) For potassium.—For internal std method, dil. required vol.  $\text{LiCl}$  stock soln to 1 L; otherwise use  $\text{H}_2\text{O}$ . (2) For sodium.—To 250 mL  $\text{NH}_4$  oxalate stock soln add required vol.  $\text{LiCl}$  stock soln (if internal std method is used) and dil. to 1 L. If internal std requirements are same for both Na and K detns, this reagent may be used as common extg soln.

#### 3.021

#### Preparation of Standard Solutions

Dil. appropriate aliquots of stock solns to prep. series of stds contg K and/or Na in stepped amts (including 0) to cover instrument range, and Li and  $\text{NH}_4$  oxalate (if required) in same concns as in corresponding extg solns. (If common extg soln is used, 1 set of stds contg both K and Na suffices.)

#### 3.022

#### Sample Extraction

Transfer weighed portion of finely ground and well mixed sample to erlenmeyer of at least twice capacity of vol. of extg soln to be used. Add measured vol. extg soln, stopper flask, and shake vigorously at frequent intervals during  $\geq 15$  min. Filter thru dry, fast paper. If paper clogs, pour contents onto addnl fresh paper and combine filtrates. Use filtrate for detn.

Note: Do not make exts more concd than required for instrument because there is tendency toward incomplete extn as ratio of sample wt to vol. extg soln increases. Prep. sep. exts for K and Na when their concns in sample differ greatly. For K, use wt sample  $\leq 0.1$  g/50 mL extg soln; for low Na concns use  $\geq 1.0$  g/50 mL extg soln; and for higher concns, prep. weaker exts by reducing ratio of sample to extg soln rather than by dilg stronger exts.

#### 3.023

#### Determination

(Caution: See 51.007.)

Rinse all glassware used in Na detn with dil.  $\text{HNO}_3$ , followed by several portions  $\text{H}_2\text{O}$ . Protect solns from air-borne Na contamination.

Operate instrument according to manufacturer's instructions. Permit instrument to reach operating equilibrium before use. Aspirate portions of std solns toward end of warm-up period until reproducible readings for series are obtained.

Run stds, covering concn range of samples involved, at frequent intervals within series of sample soln detns. Repeat this operation with both std and sample solns enough times to result in reliable av. reading for each soln. Plot curves from readings of stds, and calc. % K and/or Na in samples.

#### ★ Potassium—Official Final Action ★

#### 3.024 Platinic Chloride Method

See 3.020, 11th ed.

#### 3.025 Perchloric Acid Method (11)

See 3.021, 11th ed.

#### 3.026 Rapid Method for Potassium Only

See 3.022, 11th ed.

#### Sodium Only

#### Uranyl Acetate Method (12)—Official Final Action

#### 3.027

#### Reagent

Magnesium uranyl acetate soln:

(a) Uranyl acetate soln.—To 85 g  $\text{UO}_2(\text{OAc})_2 \cdot 2\text{H}_2\text{O}$  in 1 L vol. flask add 60 g  $\text{HOAc}$  and  $\text{H}_2\text{O}$  to ca 900 mL. Heat to dissolve, cool, and dil. to vol. with  $\text{H}_2\text{O}$ . (Caution: See 51.083.)

(b) *Magnesium acetate soln.*—To 500 g  $\text{Mg}(\text{OAc})_2 \cdot 4\text{H}_2\text{O}$  in 1 L vol. flask add 60 g HOAc and  $\text{H}_2\text{O}$  to ca 900 mL. Heat to dissolve, cool, and dil. to vol. with  $\text{H}_2\text{O}$ .

Reheat (a) and (b) sep. to ca 70° until all salts dissolve. Mix the solns at this temp. and let cool to ca 30°. Place vessel contg mixed reagent in  $\text{H}_2\text{O}$  bath at 20°, and hold 1–2 hr at 20°, or until slight excess of salts has crystd out. Filter thru dry filter into dry bottle.

### 3.028

#### Determination

Moisten 1–10 g sample with  $\text{H}_2\text{SO}_4$  (1+10), dry in oven, and ignite in furnace at 500–550° to destroy org. matter. Heat residue on steam bath with 2–5 mL HCl, add ca 40 mL  $\text{H}_2\text{O}$ , and heat to bp. Add enough 5%  $\text{CaCl}_2$  soln to ensure pptn of all phosphates. Ppt phosphates by making slightly alk. with  $\text{NH}_4\text{OH}$ . Filter, and evap. to  $\leq 5$  mL if no salts sep. Cool, add 100 mL Mg uranyl acetate soln, place mixt. in  $\text{H}_2\text{O}$  bath at 20°, and either stir vigorously 45 min or let stand 24 hr at this temp. Filter with suction, and wash with *alcohol satd with Na-Mg-uranyl acetate*. Dry 30 min at 105–110°, cool, and weigh.  $\text{Wt Na-Mg-uranyl acetate} \times 0.0153 = \text{wt Na}$ .

#### Cobalt—Official Final Action

(Caution: See 51.011, 51.040, 51.049, and 51.068.)

#### Nitrosocresol Method (13)

### 3.029

#### Reagents

(Make all distns in Pyrex stills with  $\text{F}$  joints.  
Store reagents in g-s Pyrex bottles.)

(a) *Redistilled water.*—Distil twice, or pass thru column of ion exchange resin (IR-100A, H-form, or equiv.) to remove heavy metals.

(b) *Hydrofluoric acid.*—48%. Procurement in vinyl plastic bottles is advantageous.

(c) *Perchloric acid.*—60%. No further purification necessary.

(d) *Hydrochloric acid.*—(1+1). Add equal vol. HCl to distd  $\text{H}_2\text{O}$  and distil.

(e) *Ammonium hydroxide.*—(1+1). Distil concd  $\text{NH}_4\text{OH}$  into equal vol. redistd  $\text{H}_2\text{O}$ .

(f) *Ammonium hydroxide.*—0.02N. Add 7 mL of the  $\text{NH}_4\text{OH}$  (1+1) to 2.5 L redistd  $\text{H}_2\text{O}$ .

(g) *Carbon tetrachloride.*—Distil over CaO, passing distillate thru dry, acid-washed filter paper. Used  $\text{CCl}_4$  may be recovered as in 3.044(a).

(h) *Dithizone.*—Dissolve 0.5 g dithizone in 600–700 mL  $\text{CCl}_4$  (tech. grade is satisfactory). Filter into 5 L separator contg 2.5–3.0 L 0.02N  $\text{NH}_4\text{OH}$ , shake well, and discard  $\text{CCl}_4$  layer. Shake with 50 mL portions redistd  $\text{CCl}_4$  until  $\text{CCl}_4$  phase as it seps is pure green. Add 1 L redistd  $\text{CCl}_4$  and acidify slightly with the HCl (1+1). Shake the dithizone into  $\text{CCl}_4$  layer and discard aq. layer. Store in cool, dark place, preferably in refrigerator.

(i) *Ammonium citrate soln.*—40%. Dissolve 800 g citric acid in 600 mL distd  $\text{H}_2\text{O}$ , and, while stirring, slowly add 900 mL  $\text{NH}_4\text{OH}$ . Reaction is exothermic; take care to prevent spattering. Adjust pH to 8.5, if necessary. Dil. to 2 L and ext with 25 mL portions dithizone soln until aq. phase stays orange and  $\text{CCl}_4$  remains predominantly green. Then ext soln with  $\text{CCl}_4$  until all orange is removed.

(j) *Hydrochloric acid.*—0.1N. Dil. 16.6 mL of the HCl (1+1) to 1 L with redistd  $\text{H}_2\text{O}$ .

(k) *Hydrochloric acid.*—0.01N. Dil. 100 mL of the 0.1N HCl to 1 L with redistd  $\text{H}_2\text{O}$ .

(l) *Sodium hydroxide soln.*—1N. Dissolve 40 g NaOH in 1 L redistd  $\text{H}_2\text{O}$ .

(m) *Borate buffer.*—pH 7.8. Dissolve 20 g  $\text{H}_3\text{BO}_3$  in 1 L redistd  $\text{H}_2\text{O}$ . Add 50 mL 1N NaOH and adjust pH, if necessary. Equal vols borate buffer and 0.01N HCl should give soln of pH 7.9.

(n) *Borate buffer.*—pH 9.1. To 1 L borate buffer, pH 7.8, add 120 mL 1N NaOH and adjust pH, if necessary.

(o) *Skellysolve B.*—Essentially *n*-hexane. Purify by adding 20–30 g silica gel/L, let stand several days, and distil. Available from Getty Refining and Marketing Co., PO Box 1650, Tulsa, OK 74102.

(p) *Cupric acetate soln.*—Dissolve 10 g  $\text{Cu}(\text{OAc})_2 \cdot \text{H}_2\text{O}$  in 1 L redistd  $\text{H}_2\text{O}$ .

(q) *o-Nitrosocresol soln.*—Dissolve 8.4 g anhyd.  $\text{CuCl}_2$  and 8.4 g  $\text{NH}_2\text{OH} \cdot \text{HCl}$  in 900 mL  $\text{H}_2\text{O}$ . Add 8 mL *m*-cresol (Eastman Kodak Co., practical grade) and stir vigorously while slowly adding 24 mL 30%  $\text{H}_2\text{O}_2$ . Stir mech. 2 hr at room temp. (Standing for longer periods results in excessive decomposition.) Add 25 mL HCl and ext *o*-nitrosocresol with four 150 mL portions Skellysolve B, (o), in large separator. Then add addnl 25 mL HCl and again ext with four 150 mL portions Skellysolve B. Wash combined Skellysolve B exts twice with 50–100 mL portions 0.1N HCl and twice with 50–100 mL portions redistd  $\text{H}_2\text{O}$ . Shake *o*-nitrosocresol soln with successive 50–100 mL portions 1%  $\text{Cu}(\text{OAc})_2$  soln until aq. phase is no longer deep blood-red. When light purple is evident, extn is complete. Discard Skellysolve B phase, acidify aq. soln of Cu salt with 25 mL HCl, and ext reagent with two 500 mL portions Skellysolve B; wash twice with 150–200 mL portions 0.1N HCl and several times with 150–200 mL portions redistd  $\text{H}_2\text{O}$ . Store *o*-nitrosocresol soln in refrigerator at ca 4°. Reagent is stable  $\geq 6$  months.

(r) *Sodium o-nitrosocresol soln.*—Ext 100 mL *o*-nitrosocresol by shaking with two 50 mL portions borate buffer, pH 9.1, in separator. (If this is carried out as 2 extns, resulting reagent is more concd. It is important that total vol. *o*-nitrosocresol soln equal total vol. buffer.)

(s) *Cobalt std solns.*—(1) *Stock soln.*—Heat  $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$  in oven at 250–300° to const wt (6–8 hr). Weigh exactly 0.263 g of the  $\text{CoSO}_4$  and dissolve in 50 mL redistd  $\text{H}_2\text{O}$  and 1 mL  $\text{H}_2\text{SO}_4$ . Dil. to 1 L. (2) *Working soln.*—0.5  $\mu\text{g}/\text{mL}$ . Transfer 5 mL stock soln to 1 L vol. flask and dil. to vol. with redistd  $\text{H}_2\text{O}$ .

(t) *Hydroxylamine acetate buffer.*—pH 5.1 $\pm$ 0.1. Dissolve 10 g  $\text{NH}_2\text{OH} \cdot \text{HCl}$  and 9.5 g anhyd. NaOAc in 500 mL redistd  $\text{H}_2\text{O}$ .

### 3.030

#### Apparatus

(a) *Platinum dishes.*—Approx. 70 mL; for ashing.

(b) *Automatic dispensing burets.*—100 mL; type that can be fitted to ordinary 5 lb reagent bottle and filled by means of aspirator bulb is most convenient.

(c) *Wooden separator rack.*—Twelve-unit 125 mL separator size is convenient for dithizone extns. Rack is fitted across top with removable bar padded with sponge rubber so all 12 separators can be shaken as unit.

(d) *Racks.*—Consisting of 5  $\times$  5  $\times$  65 cm (2  $\times$  2  $\times$  25") wooden bars with holes drilled at close intervals to take 50 mL centrf. tubes fitted with No. 13  $\text{F}$  glass stoppers. To make these tubes, ream out necks of heavy-wall Pyrex centrf. tubes (Rockefeller Institute type) with  $\text{F}$  C rod and grind to take  $\text{F}$  stopper. Place tubes upright in one section, and place other section (fitted with sponge rubber disks 13 mm thick in bottom of holes) across their tops. Fasten 2 sections at ends with removable rubber connectors made from ordinary tubing of convenient size, so that any number of tubes can be shaken as unit. Use these tubes for reaction of Co with nitrosocresol, extn of complex into Skellysolve B, and washing of Skellysolve B soln.

(e) *Shaking machine.*—Mech. shaker giving longitudinal stroke of 5 cm at ca 180 strokes/min; use to make dithizone extns and to ext Co complex, or shake by hand.

**3.031****Cleaning of Glassware**

Clean 120 mL Pyrex separators for dithizone extns by initially soaking 30 min in hot  $\text{HNO}_3$  and rinsing several times with  $\text{H}_2\text{O}$ . As added precaution, shake with several portions dithizone in  $\text{CCl}_4$ . After use, clean by rinsing with  $\text{H}_2\text{O}$ , drain, and stopper to avoid contamination. It is not necessary to clean every time with acid. Repeat  $\text{HNO}_3$  cleaning if blanks are unusually high.

Clean 50 mL g-s Pyrex centr. tubes by soaking 30 min in  $\text{HNO}_3$  followed by several rinsings in  $\text{H}_2\text{O}$ .

Completely submerge pipets in cylinder of chromic acid cleaning soln overnight, rinse several times with  $\text{H}_2\text{O}$ , and suspend upright in rack to dry.

Wash all other glassware thoroly in detergent and rinse well with tap  $\text{H}_2\text{O}$  followed by dip in chromic acid cleaning soln. Rinse off cleaning soln with tap  $\text{H}_2\text{O}$  followed by several distd  $\text{H}_2\text{O}$  rinses.

Clean Pt by scrubbing with sea sand followed by boiling in  $\text{HCl}$  (1+2) 30 min, and rinse several times with  $\text{H}_2\text{O}$ .

**3.032****Preparation of Sample**

See **3.002(a)**. Oven-dry all plant material 48 hr and prep. for ashing by either of following methods:

(a) Grind material in Wiley mill equipped with stainless steel sieve, mix thoroly by rolling, and sample by quartering.

(b) Using stainless steel shears, cut material by hand fine enough for convenient sampling.

**3.033****Ashing of Samples**

(Caution: See **51.011**, **51.025**, and **51.028**.)

Weigh 6 g dry plant tissue into clean Pt dish. Cover with Pyrex watch glass and place in cool furnace; heat slowly to  $500^\circ$  and hold at this temp. overnight. Remove sample and cool. Wet down ash carefully with fine stream redistd  $\text{H}_2\text{O}$ . From dispensing buret, slowly add 2–5 mL  $\text{HClO}_4$ , dropwise at first to prevent spattering. Add ca 5 mL  $\text{HF}$ , evap. on steam bath, transfer to sand bath, and keep at medium heat until fuming ceases.

Cover with Pyrex watch glass, return to partially cooled furnace, heat gradually to  $600^\circ$ , and keep at this temp. 1 hr. Remove sample and cool. Add 5 mL  $\text{HCl}$  (1+1) and ca 10 mL redistd  $\text{H}_2\text{O}$ . Replace cover glass and warm on steam bath to dissolve. (Usually clear soln essentially free of insol. material is obtained.) Transfer sample to 50 mL vol. flask, washing dish several times with redistd  $\text{H}_2\text{O}$ , dil. to vol., and mix thoroly. (Pt dishes can ordinarily be used several times between sand and acid cleanings.)

**3.034****Dithizone Extraction**

(Caution: See **51.011(b)**, **51.028(a)** and (d), and **51.049**.)

Transfer suitable aliquot (2–3 g dry material) to 120 mL separator (use petroleum jelly as stopcock lubricant). Add 5 mL  $\text{NH}_4$  citrate soln and 1 drop phthln; adjust to pH 8.5 with  $\text{NH}_4\text{OH}$  (1+1). If ppt forms, add addnl  $\text{NH}_4$  citrate. Add 10 mL dithizone in  $\text{CCl}_4$  and shake 5 min. Drain  $\text{CCl}_4$  phase into 100 mL beaker. Repeat as many times as necessary, using 5 mL dithizone soln and shaking 5 min each time. Extn is complete when aq. phase remains orange and  $\text{CCl}_4$  phase remains predominantly green. Then add 10 mL  $\text{CCl}_4$ , shake 5 min, and combine with  $\text{CCl}_4$  ext. Final 10 mL  $\text{CCl}_4$  should be pure green. If not, extn was incomplete and must be repeated.

Add 2 mL  $\text{HClO}_4$  to combined  $\text{CCl}_4$  exts, cover beaker with Pyrex watch glass, and digest on hot plate until colorless. Remove cover glass and evap. slowly to dryness. (If sample is heated any length of time at high temp. when dry, losses of Co

may occur. Heat only enough to evap. completely to dryness. If free acid remains, it interferes with next step where pH control is important.)

Add 5 mL 0.01N  $\text{HCl}$  to residue. Heat slightly to assure soln. If Cu is to be detd, transfer with redistd  $\text{H}_2\text{O}$  to 25 mL vol. flask, and dil. to vol. Transfer 20 mL aliquot to 50 mL g-s centr. tube or 60 mL separator and reserve remainder for Cu detn, **3.043**. If Cu is not to be detd, transfer entire acid soln with redistd  $\text{H}_2\text{O}$  to centr. tube or separator.

**3.035****Determination**

Add 5 mL borate buffer, pH 7.8, and 2 mL freshly prepd Na *o*-nitrosocresol soln to sample soln. Add exactly 5 mL Skellysolve B and shake 10 min. Remove aq. phase by moderate suction thru finely-drawn glass tube. To Skellysolve B layer add 5 mL  $\text{Cu}(\text{OAc})_2$  soln and shake 1 min to remove excess reagent. Again remove and discard aq. phase. Wash Skellysolve B by shaking 1 min with 5 mL redistd  $\text{H}_2\text{O}$ , removing aq. layer as before; finally shake Skellysolve B 1 min with 5 mL  $\text{NH}_2\text{OH}\cdot\text{NaOAc}$  buffer to reduce Fe. Transfer Skellysolve B soln of the Co complex to 5 cm cell and read in spectrophtr as close as possible to point of max. A, 360 nm.

**3.036****Blanks and Standards**

With each set of detns include ashing blank and Co stds of 0.0, 0.5, and 1.0  $\mu\text{g}$ . Beer's law holds for this range. A of 0.0  $\mu\text{g}$  point should be  $<0.05$ . If above, repurify *o*-nitrosocresol by transferring alternately to aq. phase as Cu salt and to Skellysolve B phase as free compd after acidifying aq. phase.

It is also advisable to include std sample with each set of samples to detect contamination or unusual losses of Co in method. Com. buckwheat flour contg 0.05 ppm Co has proved satisfactory for this purpose.

**3.037****Calculations**

Express results in terms of ppm Co, based upon dry wt of sample.

$$\text{ppm Co} = (\mu\text{g Co/mL dithizone aliquot}) \times (\text{mL total soln/g dry sample})$$

Value for  $\mu\text{g Co}$  is obtained from curve minus ashing blank.

**Nitroso-R-Salt Method (14)****3.038****Reagents**

Those listed in **3.029** and following:

(a) *Nitroso-R-salt soln.*—0.2%. Dissolve 2 g powd nitroso-R-salt (Eastman Kodak Co., No. 1124) in redistd  $\text{H}_2\text{O}$ , **3.029(a)**, and dil. to 1 L.

(b) *Dilute nitric acid.*—(1+1). Dil.  $\text{HNO}_3$  with equal vol.  $\text{H}_2\text{O}$  and redistil in Pyrex app. Store in Pyrex bottles.

(c) *Bromine water.*—Satd soln of Br in redistd  $\text{H}_2\text{O}$ , **3.029(a)**.

(d) *Citric acid soln.*—0.2N. Use special reagent grade Pb-free citric acid.

**3.039****Preparation and Ashing of Samples**

Proceed as in nitrosocresol method, **3.032–3.033**, thru "(Usually clear soln essentially free of insol. material is obtained.)" except use 10 g instead of 6 g dry plant tissue.

**3.040****Dithizone Extraction**

Transfer entire soln to 120 mL separator, and proceed as in **3.034**, thru "If free acid remains . . . pH control is important." Dissolve in 1 mL citric acid soln, (d), transfer to 25 mL vol. flask, and dil. to vol. with redistd  $\text{H}_2\text{O}$ , **3.029(a)**.

## 3.041

**Determination**

Transfer suitable aliquot (ca 8 g dry material) of citric acid soln, **3.040**, to 50 mL beaker. Evap. to 1–2 mL. Add 3 mL borate buffer, **3.029(n)**, and adjust pH to 8.0–8.5 with NaOH (check externally with *phenol red*). (Vol.  $\leq 5$  mL.) Add 1 mL nitroso-R-salt soln *slowly with mixing*. Boil 1–2 min and add 2 mL dil.  $\text{HNO}_3$ . Boil 1–2 min, add 0.5–1.0 mL  $\text{Br-H}_2\text{O}$ , cover with watch glass, and let stand warm 5 min. Boil 2–3 min to remove excess Br (use effective fume removal device). Cool, and dil. to 10 or 25 mL (depending on length of light path in absorption cell). Transfer to cell and read at 500 nm within 1 hr. Prep. stds contg 0.5, 1, 2, 3, and 4  $\mu\text{g}$  Co and add 1 mL citric acid soln, **3.038(d)**, to each. Proceed as for unknowns, beginning "Evap. to 1–2 mL."

**Copper (14)—Official Final Action**

## 3.042

**Reagents**

Those listed in **3.029** and following:

(a) *Sodium diethyldithiocarbamate soln.*—0.1%. Freshly prepd in redistd  $\text{H}_2\text{O}$ , **3.029(a)**.

(b) *Copper std soln.*—1  $\mu\text{g}/\text{mL}$ . Dissolve 0.3929 g  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  in redistd  $\text{H}_2\text{O}$ , **3.029(a)**, add 5 mL  $\text{H}_2\text{SO}_4$ , dil. to 1 L, and mix. Take 10 mL aliquot, add 5 mL  $\text{H}_2\text{SO}_4$ , dil. to 1 L, and mix.

## 3.043

**Determination**

Transfer aliquot (0.5–1 g dry material) from soln obtained from **3.034** or **3.040** to 125 mL separator. Add 2 mL  $\text{NH}_4$  citrate soln, 1 drop phthln, 5 mL Na diethyldithiocarbamate soln, and  $\text{NH}_4\text{OH}$  (1+1), **3.029(e)**, until pink. Add 10 mL  $\text{CCl}_4$  and shake 5 min. Drain  $\text{CCl}_4$ , centr. 5 min, transfer to absorption cell, and read at max.  $A$ , ca 430 nm.

Prep. std curve with 0, 1, 5, 10, 15, and 20  $\mu\text{g}$  Cu treated as above.

**Zinc—Official Final Action****Mixed Color Method (15)**

## 3.044

**Reagents**

(Redistil all  $\text{H}_2\text{O}$  from Pyrex. Treat all glassware with  $\text{HNO}_3$  (1+1) or fresh chromic acid cleaning soln. Rinse repeatedly with ordinary distd  $\text{H}_2\text{O}$  and finally with Zn-free  $\text{H}_2\text{O}$ .)

(a) *Carbon tetrachloride.*—Use ACS grade without purification. If tech. grade is used, dry with anhyd.  $\text{CaCl}_2$  and redistil in presence of small amt  $\text{CaO}$ . (Used  $\text{CCl}_4$  may be reclaimed by distn in presence of NaOH (1+100) contg small amts of  $\text{Na}_2\text{S}_2\text{O}_3$ , followed by drying with anhyd.  $\text{CaCl}_2$  and fractional distn in presence of small amts of  $\text{CaO}$ .) (Caution: See **51.011(b)** and **51.049**.)

(b) *Zinc std solns.*—(1) *Stock soln.*—1 mg/mL. Place 0.25 g pure Zn in 250 mL vol. flask. Add ca 50 mL  $\text{H}_2\text{O}$  and 1 mL  $\text{H}_2\text{SO}_4$ ; heat on steam bath until all Zn dissolves. Dil. to vol. and store in Pyrex vessel. (2) *Working soln.*—10  $\mu\text{g}/\text{mL}$ . Dil. 10 mL stock soln to 1 L. Store in Pyrex vessel.

(c) *Ammonium hydroxide soln.*—1*N*. With all-Pyrex app. distil  $\text{NH}_4\text{OH}$  into  $\text{H}_2\text{O}$ , stopping distn when half has distd. Dil. distillate to proper concn. Store in g-s Pyrex vessel.

(d) *Hydrochloric acid.*—1*N*. Displace HCl gas from HCl in glass flask by slowly adding equal vol.  $\text{H}_2\text{SO}_4$  from dropping funnel that extends below surface of the HCl. Conduct displaced HCl gas thru delivery tube to surface of  $\text{H}_2\text{O}$  in receiving flask (no heat is necessary). Dil. to proper concn. Use of 150 mL each of HCl and  $\text{H}_2\text{SO}_4$  will yield 1 L purified HCl soln of concn  $>1\text{N}$ .

(e) *Diphenylthiocarbazone (dithizone) soln.*—Dissolve 0.20 g dithizone in 500 mL  $\text{CCl}_4$ , and filter to remove insol. matter. Place soln in g-s bottle or large separator, add 2 L 0.02*N*  $\text{NH}_4\text{OH}$  (40

mL 1*N*  $\text{NH}_4\text{OH}$  dild to 2 L), and shake to ext dithizone into aq. phase. Sep. phases, discard  $\text{CCl}_4$ , and ext ammoniacal soln of dithizone with 100 mL portions  $\text{CCl}_4$  until  $\text{CCl}_4$  ext is pure green. Discard  $\text{CCl}_4$  after each extn. Add 500 mL  $\text{CCl}_4$  and 45 mL 1*N* HCl, and shake to ext dithizone into  $\text{CCl}_4$ . Sep. phases and discard aq. phase. Dil.  $\text{CCl}_4$  soln of dithizone to 2 L with  $\text{CCl}_4$ . Store in brown bottle in dark, cool place.

(f) *Ammonium citrate soln.*—0.5*M*. Dissolve 226 g  $(\text{NH}_4)_2\text{HC}_6\text{H}_5\text{O}_7$  in 2 L  $\text{H}_2\text{O}$ . Add  $\text{NH}_4\text{OH}$  (80–85 mL) to pH of 8.5–8.7. Add excess dithizone soln (aq. phase is orange-yellow after phases have been shaken and sepd), and ext with 100 mL portions  $\text{CCl}_4$  until ext is full green. Add more dithizone if necessary. Sep. aq. phase from  $\text{CCl}_4$  and store in Pyrex vessel.

(g) *Carbamate soln.*—Dissolve 0.25 g Na diethyldithiocarbamate in  $\text{H}_2\text{O}$  and dil. to 100 mL with  $\text{H}_2\text{O}$ . Store in refrigerator in Pyrex bottle. Prep. fresh after 2 weeks.

(h) *Dilute hydrochloric acid.*—0.02*N*. Dil. 100 mL 1*N* HCl to 5 L.

## 3.045

**Preparation of Solutions**

To reduce measuring out reagents and minimize errors due to variations in composition, prep. 3 solns in appropriate amts from reagents and store in Pyrex vessels, taking care to avoid loss of  $\text{NH}_3$  from *Solns 1* and 2. Discard solns after 6–8 weeks because Zn increases slowly with storage. Det. std curve for each new set of reagents. Following amts of *Solns 1* and 2 and 2 L dithizone soln are enough for 100 detns:

(1) *Soln 1.*—Dil. 1 L 0.5*M*  $\text{NH}_4$  citrate and 140 mL 1*N*  $\text{NH}_4\text{OH}$  to 4 L.

(2) *Soln 2.*—Dil. 1 L 0.5*M*  $\text{NH}_4$  citrate and 300 mL 1*N*  $\text{NH}_4\text{OH}$  to 4.5 L. Just before using, add 1 vol. carbamate soln to 9 vols  $\text{NH}_3\text{-NH}_4$  citrate soln to obtain vol. of *Soln 2* immediately required.

*Note:* If Zn-free reagents have been prepd, they can be used to test chemicals for Zn. Certain lots of  $\text{NH}_4\text{OH}$  and HCl are sufficiently free of Zn to be used without purification.

## 3.046

**Ashing**

Ash 5 g finely ground, air-dried plant material in Pt dish in furnace at 500–550°. Include blank detn. Moisten ash with little  $\text{H}_2\text{O}$ ; then add 10 mL 1*N* HCl (more if necessary) and heat on steam bath until all substances sol. in HCl are dissolved. Add 5–10 mL hot  $\text{H}_2\text{O}$ . Filter off insol. matter on 7 cm paper (Whatman No. 42, or equiv., previously washed with two 5 mL portions hot 1*N* HCl, then washed with hot  $\text{H}_2\text{O}$  until HCl-free), and collect filtrate in 100 mL vol. flask. Wash filter with hot  $\text{H}_2\text{O}$  until washings are not acid to Me red. Add 1 drop Me red, **2.055(i)**, to filtrate in 100 mL flask; neutze with 1*N*  $\text{NH}_4\text{OH}$  and add 4 mL 1*N* HCl. Cool, and dil. to vol. with  $\text{H}_2\text{O}$ .

## 3.047

**First Extraction**

(Sepn of dithizone complex-forming metals from ash soln)

Pipet aliquot of ash soln contg  $\leq 30 \mu\text{g}$  Zn into 125 mL Squibb separator. Add 1 mL 0.2*N* HCl for each 5 mL ash soln  $<10$  mL taken, or 1 mL 0.2*N*  $\text{NH}_4\text{OH}$  for each 5 mL  $>10$  mL taken. (10 mL aliquot is usually satisfactory in analysis of plant materials.) Add 40 mL *Soln 1* and 10 mL dithizone reagent. Shake vigorously 30 sec to ext from aq. phase the Zn and other dithizone complex-forming metals that may be present; then let layers sep. At this point excess dithizone (indicated by orange or yellow-orange aq. phase) must be present. If excess dithizone is not present, add more reagent until, after shaking, excess is indicated. Shake down the drop of  $\text{CCl}_4$  ext from surface, and drain  $\text{CCl}_4$  ext into second separator as completely as possible without letting any aq. layer enter stopcock bore. Rinse down  $\text{CCl}_4$  ext from surface

of aq. layer with 1–2 mL clear  $\text{CCl}_4$ ; then drain this  $\text{CCl}_4$  into second separator without letting aq. phase enter stopcock bore. Repeat rinsing process as often as necessary to flush ext completely into second separator. Add 5 mL clear  $\text{CCl}_4$  to first separator, shake 30 sec, and let layers sep. ( $\text{CCl}_4$  layer at this point will appear clear green if metals that form dithizone complexes have been completely extd from aq. phase by previous extn.) Drain  $\text{CCl}_4$  layer into second separator and flush ext down from surface of aq. phase, and as completely previously. If last ext does not possess distinct clear color, repeat extn with 5 mL clear  $\text{CCl}_4$  and flushing-out process until complete extn of dithizone complex-forming metals is assured; then discard aq. phase.

**3.048****Second Extraction**

(Sepn of Cu by extn of Zn into 0.02N HCl)

Pipet 50 mL 0.02N HCl into separator contg  $\text{CCl}_4$  soln of metal dithizonates. Shake vigorously 1.5 min, and let layers sep. Shake down drop from surface of aq. phase, and as completely as possible drain  $\text{CCl}_4$  phase contg all Cu as dithizonate, without letting any aq. phase, which contains all the Zn, enter stopcock bore. Rinse down  $\text{CCl}_4$  ext from surface of aq. phase, and rinse out stopcock bore with 1–2 mL portions clear  $\text{CCl}_4$  (same as in first extn) until all traces of green dithizone have been washed out of separator. Shake down drop of  $\text{CCl}_4$  from surface of aq. phase, and drain  $\text{CCl}_4$  as completely as possible without letting any aq. phase enter stopcock bore. Remove stopper from separator and lay it across neck until small amt of  $\text{CCl}_4$  on surface of aq. phase evaps.

**3.049****Final Extraction**

(Extn of Zn in presence of carbamate reagent)

Pipet 50 mL *Soln 2* and 10 mL dithizone soln into 50 mL 0.02N HCl soln contg the Zn. Shake 1 min and let phases sep. Flush out stopcock and stem of separator with ca 1 mL  $\text{CCl}_4$  ext; then collect remainder in test tube. Pipet 5 mL ext into 25 mL vol. flask, dil. to vol. with clear  $\text{CCl}_4$ , and measure *A* with spectrophtr set at absorption max., ca 525 nm. (*Caution:* Protect final ext from sunlight as much as possible and read within 2 hr.)

Det. Zn present in aliquot from curve relating *A* and concn, correct for Zn in blank, and calc. % Zn in sample.

**3.050****Standard Curve**

Place 0, 5, 10, 15, 20, 25, 30, and 35 mL Zn working std soln in 100 mL vol. flasks. To each flask add 1 drop Me red and neutze with 1N  $\text{NH}_4\text{OH}$ ; then add 4 mL 1N HCl and dil. to vol. Proceed exactly as for ash solns, beginning with first extn, and using 10 mL aliquots of each of the Zn solns (0, 5, 10, 15, 20, 25, 30, and 35  $\mu\text{g}$  Zn, resp.). Construct std curve by plotting  $\mu\text{g}$  Zn against *A*.

**Single Color Method (16)****3.051****Reagents**

See 3.044–3.045 plus following:

(a) *Dilute dithizone soln.*—Dil. 1 vol. dithizone soln, 3.044(e), with 4 vols  $\text{CCl}_4$ .

(b) *Carbamate soln.*—Dissolve 1.25 g Na diethyldithiocarbamate in  $\text{H}_2\text{O}$  and dil. to 1 L. Store in refrigerator and prep. fresh after long periods of storage.

(c) *Dilute ammonium hydroxide.*—Dil. 20 mL 1N  $\text{NH}_4\text{OH}$ , 3.044(c), to 2 L.

**3.052****Ashing**

Weigh 2 g sample finely ground plant material into well-glazed porcelain, Vycor, or Pt crucible, include crucible for blank detn, and heat in furnace at 500–550° until ashing is complete. Cool, moisten ash with little  $\text{H}_2\text{O}$ , add 10 mL 1N HCl (more if necessary to ensure excess of acid), and heat on steam bath until all sol. material dissolves. Add few mL hot  $\text{H}_2\text{O}$  and filter thru quant. paper into 200 mL vol. flask. Wash paper with hot  $\text{H}_2\text{O}$  until washings are not acid to Me red. Add 2 drops Me red soln to filtrate, neutze with 1N  $\text{NH}_4\text{OH}$ , add exactly 3.2 mL 1N HCl, dil. to vol. with  $\text{H}_2\text{O}$ , and mix.

**3.053****Formation of Zinc Dithizonate**

(Removal of interferences and  
sepn of excess dithizone)

Pipet aliquot of ash soln contg  $\leq 15 \mu\text{g}$  Zn into 125 mL amber glass separator. (25 mL aliquot is usually satisfactory.) If necessary to use different vol., add 0.4 mL 0.2N HCl for each 5 mL less, or 0.4 mL 0.2N  $\text{NH}_4\text{OH}$  for each 5 mL more, than 25 mL taken. If  $< 25$  mL of the soln is taken, add  $\text{H}_2\text{O}$  to 25 mL.

Add 10 mL dithizone reagent, 3.044(e), to aliquot in separator and shake vigorously 1 min. Let layers sep. and discard  $\text{CCl}_4$  layer. Add 2 mL  $\text{CCl}_4$  to aq. soln, let layers sep., and discard  $\text{CCl}_4$ . Repeat this rinsing once. Then add 5 mL  $\text{CCl}_4$ , shake vigorously 15 sec, let layers sep., and discard  $\text{CCl}_4$ . Rinse once more with 2 mL  $\text{CCl}_4$  as above. Discard  $\text{CCl}_4$  layer and let  $\text{CCl}_4$  remaining on surface of soln in funnel evap. before proceeding.

Add 40 mL  $\text{NH}_4$  citrate *Soln 1*, 3.045(1), 5 mL carbamate soln, 3.051(b), and 25 mL dil. dithizone reagent, 3.051(a). Accurately add carbamate and dithizone reagents from pipet or buret. Shake vigorously 1 min. Let layers sep. and draw off aq. layer thru fine tip glass tube connected to aspirator with rubber tubing. To remove excess dithizone from  $\text{CCl}_4$  layer, add 50 mL 0.01N  $\text{NH}_4\text{OH}$  and shake vigorously 30 sec.

**3.054****Determination**

Dry funnel stem with pipestem cleaner and flush out with ca 2 mL of the Zn dithizonate soln. Collect adequate portion of remaining soln in 25 mL erlenmeyer, or other suitable container, and stopper tightly. (Amber glass containers are convenient, but colorless glassware will suffice if solns are kept in dark until *A* readings are made.)

Measure *A* of each soln against  $\text{CCl}_4$  with spectrophtr set at absorption max., ca 535 nm. Correct for Zn in blank detns. Calc. amt Zn present in soln from curve relating concn and *A*.

**3.055****Standard Curve**

Into 200 mL vol. flasks place 0, 2, 4, 6, 8, 10, 12, and 14 mL, resp., Zn working std soln. To each flask add 2 drops Me red soln, neutze with 1N  $\text{NH}_4\text{OH}$ , add 3.2 mL 1N HCl, and dil. to vol. with  $\text{H}_2\text{O}$ . Pipet 25 mL aliquots of each of these solns, contg 0, 2.5, 5, 7.5, 10, 12.5, 15, and 17.5  $\mu\text{g}$  Zn, resp., into amber glass separators, and proceed as for ash solns, 3.053, beginning with second par. Det. *A* of each soln and plot values against corresponding amts Zn.

**Molybdenum (17)—Official Final Action****3.056****Apparatus**

*Photoelectric colorimeter or spectrophotometer.*—Capable of isolating band at ca 465 nm. (Photometer equipped with filter with max. *T* at 440–460 nm and 1 cm cells of 10 mL capacity is suitable.)

## 3.057

**Reagents**

(a) *Isoamyl alcohol*.—Reagent grade 3-methyl-1-butanol, bp 128–132°.

(b) *Dilute hydrochloric acid*.—(1) 20% soln.—Dil. concd HCl to ca 20% HCl (1+1.85). (2) 6*N* soln.—Stdze to second decimal place.

(c) *Iron std soln*.—100 µg/mL. Dissolve 0.7022 g  $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 1 mL  $\text{H}_2\text{SO}_4$ , and dil. to 1 L.

(d) *Molybdenum std solns*.—(1) *Stock soln*.—100 µg/mL. Dissolve 0.0920 g  $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 500 mL. (2) *Working soln*.—5 µg/mL. Dil. 25 mL stock soln to 500 mL.

(e) *Potassium thiocyanate soln*.—20%. Dissolve 50 g KSCN in  $\text{H}_2\text{O}$  and dil. to 250 mL.

(f) *Sodium fluoride saturated soln*.—Add 200 mL  $\text{H}_2\text{O}$  to ca 10 g NaF. Stir until satd and filter.

(g) *Stannous chloride solns*.—(1) 20% soln.—Weigh 10 g  $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$  into beaker, add 10 mL 20% HCl, (b)(1), and heat until completely dissolved. Cool, add granule of metallic Sn, dil. to 50 mL with  $\text{H}_2\text{O}$ , and store in g-s bottle. (2) 0.8% wash soln.—Dil. 4 mL 20% soln to 100 mL with  $\text{H}_2\text{O}$ .

## 3.058

**Determination**

(Caution: See 51.019, 51.026, and 51.028.)

Weigh 1–5 g finely ground sample, contg  $\leq 35$  µg Mo, into 200 mL tall-form Pyrex beaker. To 1, 2, or 5 g samples add 10, 15, or 35 mL  $\text{HNO}_3$ , resp. Include 2 beakers for blanks. Cover beaker with cover glass, and let stand ca 15 min; then heat cautiously on steam bath or hot plate at ca 100°, avoiding frothing over top. If froth approaches cover glass, remove beaker from heat until frothing subsides; then continue heating. Digest, usually ca 2 hr, until most of solids disappear.

Cool to room temp. If contents should go to dryness, add few mL  $\text{HNO}_3$ . Add 6 mL 70–72%  $\text{HClO}_4$ , cover beaker, place on hot plate, and gradually raise temp. so that contents boil vigorously but do not bump. Continue heating until digestion is complete as indicated by liq. becoming colorless or pale yellow. If necessary, make repeated addns of  $\text{HNO}_3$  and  $\text{HClO}_4$  and continue to digest until C is completely oxidized.

After digestion is complete, place cover glass slightly to one side of top of beaker, or replace it with elevated watch glass, and evap. just to dryness or until residue appears only slightly moist. Remove beaker from hot plate, and cool. Wash down sides of beaker and underside of cover glass with few mL  $\text{H}_2\text{O}$ , return to hot plate, and boil few min. Remove from hot plate, cool, and again rinse sides of beaker and cover glass with small amt  $\text{H}_2\text{O}$ .

Add 2 drops Me orange and neutze with  $\text{NH}_4\text{OH}$ . Add 6*N* HCl, dropwise with stirring, until soln is just acid; then add 8.2 mL excess to give final concn of ca 3% HCl. Add 2 mL satd NaF soln, and 1 mL Fe soln, if sample contains  $< 100$  µg Fe.

Transfer soln to 125 mL separator and dil. to 50 mL with  $\text{H}_2\text{O}$ . Add 4 mL 20% KSCN soln, mix thoroly, and add 1.5 mL 20%  $\text{SnCl}_2$  soln. Mix again, and from buret or pipet, add exactly 15 mL isoamyl alcohol. Stopper separator and shake vigorously 1 min, let phases sep., and drain and discard aq. layer. Ext into alcohol without delay, since colored complex is somewhat unstable in aq. soln.

Add 25 mL freshly prepd 0.8%  $\text{SnCl}_2$  wash soln, and shake gently 15 sec. Let phases sep., and drain and discard aq. layer. Transfer isoamyl alcohol soln to centr. tube, and centr. 5 min at ca 2000 rpm to remove  $\text{H}_2\text{O}$  droplets. If alcohol layer is not clear, recentrf. Stopper tubes to prevent evapn, if A readings cannot be made immediately.

Compare unknown solns with isoamyl alcohol at ca 465 nm

in spectrophtr, and make appropriate corrections in A readings for Mo in blanks. Obtain Mo concn from calibration curve relating A readings to concns of series of solns of known Mo content.

Prep. calibration curve for instrument used, as follows: Place aliquots of working std soln contg 0, 5, 10, 15, 20, 25, 30, and 35 µg Mo, resp., into 200 mL tall-form beakers and carry them thru entire detn, beginning with digestion with  $\text{HNO}_3$  and  $\text{HClO}_4$ . Plot A against corresponding Mo concns.

**NONMETALS****Arsenic—Official Final Action**

## 3.059

**Preparation of Solution**

See 25.008.

## 3.060

**Determination**

Proceed as in 25.009, or take aliquot and det. as in 6.013, beginning "... add 3 mL  $\text{H}_2\text{SO}_4$ , ..."

**Sulfur—Official Final Action****Sodium Peroxide Method (18)**

(Caution: See 51.035.)

## 3.061

**Preparation of Solution**

Place 1.5–2.5 g sample in ca 100 mL Ni crucible and add 5 g anhyd.  $\text{Na}_2\text{CO}_3$ . Mix thoroly, using Ni or Pt rod, and moisten with ca 2 mL  $\text{H}_2\text{O}$ . Add  $\text{Na}_2\text{O}_2$ , ca 0.5 g at time, mixing thoroly after each addn, and continue until mixt. becomes nearly dry and quite granular (ca 5 g  $\text{Na}_2\text{O}_2$ ). Place crucible over S-free flame or elec. hot plate and heat carefully, stirring occasionally, until contents are fused. (If material ignites, detn is worthless.)

After fusion, remove crucible, let cool somewhat, and cover hardened mass with more  $\text{Na}_2\text{O}_2$  to depth of ca 5 mm. Heat gradually and finally with full flame until fusion again takes place, rotating crucible occasionally to bring any particles adhering to sides into contact with oxidizing material. Continue heating 10 min after fusion is complete. Cool somewhat, place warm crucible and contents in 600 mL beaker, and carefully add ca 100 mL  $\text{H}_2\text{O}$ . After initial violent action ceases, wash material out of crucible, make slightly acid with HCl (adding small portions at time), transfer to 500 mL vol. flask, cool, dil. to vol., and filter.

## 3.062

**Determination**

Dil. aliquot of prepd soln to ca 200 mL with  $\text{H}_2\text{O}$  and add HCl until ca 0.5 mL free acid is present. Heat to bp and add 10 mL 10%  $\text{BaCl}_2$  soln dropwise with constant stirring. Continue boiling ca 5 min, and let stand  $\geq 5$  hr in warm place. Decant thru ashless paper or ignited and weighed gooch. Add 15–20 mL boiling  $\text{H}_2\text{O}$  to ppt, transfer to filter, and wash with boiling  $\text{H}_2\text{O}$  until filtrate is Cl-free. Dry ppt and filter, ignite, and weigh as  $\text{BaSO}_4$ . Wt ppt  $\times 0.1374 = \text{S}$ .

**Magnesium Nitrate Method (19)**

## 3.063

**Preparation of Solution**

Weigh 1 g sample into large porcelain crucible. Add 7.5 mL  $\text{Mg}(\text{NO}_3)_2$  soln, 2.019, so that all material comes in contact with soln. (It is important that enough  $\text{Mg}(\text{NO}_3)_2$  soln be added to ensure complete oxidn and fixation of the S present. For larger samples and for samples with high S content, proportionally larger vol. of this soln must be used.) Heat on elec. hot plate

(180°) until no further action occurs. Transfer crucible while hot to furnace ( $\leq 500^\circ$ ) and let it remain until sample is thoroly oxidized. (No black particles should remain. If necessary, break up sample and return to furnace.) Remove crucible and let cool. Add  $\text{H}_2\text{O}$ ; then  $\text{HCl}$  in excess. Bring soln to boil, filter, and wash thoroly. If preferred, transfer soln to 250 mL vol. flask before filtering and dil. to vol. with  $\text{H}_2\text{O}$ .

**3.064****Determination**

Dil. entire filtered soln, **3.063**, to 200 mL, or take 100 mL aliquot of the measured vol., dil. to 200 mL, and proceed as in **3.062**.

**Phosphorus (20)—Official Final Action****3.065 ★ Macro Method ★**

(a) *For samples exceedingly high in P and low in Ca and Mg (certain seeds, grains, etc.)*—Prep. soln as in **3.063**, or evap. filtrate and washings from S detn, **3.062**, to 50 mL, and proceed as in **8.033**.

(b) *For other samples.*—Take 50 mL aliquot of Soln I, **3.005**, and proceed as in **8.033**.

**Micro Method (21)****3.066****Reagents**

(a) *Phosphorus std soln.*—0.025 mg P/mL. Dissolve 0.4394 g pure dry  $\text{KH}_2\text{PO}_4$  in  $\text{H}_2\text{O}$  and dil. to 1 L. Dil. 50 mL of this soln to 200 mL.

(b) *Ammonium molybdate soln.*—Dissolve 25 g  $\text{NH}_4$  molybdate in 300 mL  $\text{H}_2\text{O}$ . Dil. 75 mL  $\text{H}_2\text{SO}_4$  to 200 mL and add to  $\text{NH}_4$  molybdate soln.

(c) *Hydroquinone soln.*—Dissolve 0.5 g hydroquinone in 100 mL  $\text{H}_2\text{O}$ , and add 1 drop  $\text{H}_2\text{SO}_4$  to retard oxidn.

(d) *Sodium sulfite soln.*—Dissolve 200 g  $\text{Na}_2\text{SO}_3$  in  $\text{H}_2\text{O}$ , dil. to 1 L, and filter. Either keep this soln well stoppered or prep. fresh each time.

**3.067****Preparation of Solution**

To 1 or 2 g sample in small porcelain crucible add 1 mL  $\text{Mg}(\text{NO}_3)_2$  soln, **2.019**, and place on steam bath. After few min, cautiously add few drops  $\text{HCl}$ , taking care that gas evolution does not push portions of sample over edge of crucible. Make 2 or 3 further addns of few drops  $\text{HCl}$  while sample is on bath so that as it approaches dryness it tends to char. If contents become too viscous for further drying on bath, complete drying on hot plate. Cover crucible, transfer to cold furnace, and ignite 6 hr at  $500^\circ$ , or until even gray ash is obtained. (If necessary, cool crucible, dissolve ash in little  $\text{H}_2\text{O}$  or alc.-glycerol, evap. to dryness, and return uncovered to furnace 4–5 hr longer.) Cool, take up with  $\text{HCl}$  (1+4), and transfer to 100 mL beaker. Add 5 mL  $\text{HCl}$  and evap. to dryness on steam bath to dehydrate  $\text{SiO}_2$ . Moisten residue with 2 mL  $\text{HCl}$ , add ca 50 mL  $\text{H}_2\text{O}$ , and heat few min on bath. Transfer to 100 mL vol. flask, cool immediately, dil. to vol., mix, and filter, discarding first portion of filtrate.

**3.068****Determination**

To 5 mL aliquot filtrate in 10 mL vol. flask add 1 mL  $\text{NH}_4$  molybdate soln, rotate flask to mix, and let stand few sec. Add 1 mL hydroquinone soln, again rotate flask, and add 1 mL  $\text{Na}_2\text{SO}_3$  soln. (Last 3 addns may be made with Mohr pipet.) Dil. to vol. with  $\text{H}_2\text{O}$ , stopper flask with thumb or forefinger, and shake to mix thoroly. Let stand 30 min, and measure  $A$  with spectrophot set at 650 nm. Report as % P.

**Gravimetric Quinolinium Molybdophosphate Method (22)—Official Final Action****3.069****Preparation of Solution**

Accurately weigh ca 2 g plant sample in porcelain dish, and add 7.5 mL  $\text{Mg}(\text{NO}_3)_2$  soln, **2.019**. Dry in oven 2 hr at  $110$ – $115^\circ$  (or until dry). Ignite carefully over Fisher burner, or equiv., until bubbling and smoking cease. Complete ashing in furnace 4 hr at  $550$ – $600^\circ$ . Dissolve ash in few mL  $\text{HCl}$  (2+1) and evap. to dryness on steam bath. Take up residue in 10–15 mL  $\text{HCl}$  (1+9) and filter thru coarse paper into 200 mL vol. flask. Wash paper thoroly with  $\text{H}_2\text{O}$  and let filtrate cool to room temp. Dil. to vol. with  $\text{H}_2\text{O}$ .

**3.070****Determination**

Pipet 40 mL aliquot into 300 or 500 mL erlenmeyer and proceed as in **2.028**.

**Chlorine (23)—Official Final Action**

(If bromides or iodides are present in significant amts, correct results accordingly.)

**3.071****Preparation of Solution**

Verify complete retention of Cl in each kind of material by trial, since losses can occur, especially with samples high in carbohydrates, if insufficient  $\text{Na}_2\text{CO}_3$  is present during ignition, or in any case if excessive temp. is used.

Moisten 5 g sample in Pt dish with 20 mL 5%  $\text{Na}_2\text{CO}_3$  soln, evap. to dryness, and ignite as thoroly as possible at  $\leq 500^\circ$ . Ext with hot  $\text{H}_2\text{O}$ , filter, and wash. Return residue to Pt dish and ignite to ash; dissolve in  $\text{HNO}_3$  (1+4), filter, wash thoroly, and add this soln to  $\text{H}_2\text{O}$  ext.

**3.072****Gravimetric Method**

To prepd soln, add 10%  $\text{AgNO}_3$ , avoiding more than slight excess. Heat to bp, protect from light, and let stand until ppt coagulates. Filter on weighed gooch, previously heated to  $140$ – $150^\circ$ , and wash with hot  $\text{H}_2\text{O}$ , testing filtrate to prove excess of  $\text{AgNO}_3$ . Dry  $\text{AgCl}$  at  $140$ – $150^\circ$ , cool, and weigh. Report as % Cl.

**Volumetric Method I (24)**

(Since precision of this titrn is considered to be  $\pm 0.2$  mg Cl, accuracy of 1.0% requires samples contg  $\geq 20$  mg.)

**3.073****Reagents**

(a) *Silver nitrate std soln.*—1 mL = 0.00355 g Cl. Prep. soln slightly stronger than 0.1N, stdze as in **50.031**, and adjust to exactly 0.1N.

(b) *Ammonium or potassium thiocyanate std soln.*—0.1N. Prep. soln slightly stronger than 0.1N, stdze as in **50.030(b)**, and adjust to exactly 0.1N.

(c) *Ferric indicator.*—Satd soln of  $\text{FeNH}_4(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ .

(d) *Nitric acid.*—Free from lower oxides of N by dilg  $\text{HNO}_3$  with ca  $\frac{1}{4}$  vol.  $\text{H}_2\text{O}$ , and boiling until perfectly colorless.

**3.074****Determination**

To prepd soln, **3.071**, add known vol. std  $\text{AgNO}_3$  soln in slight excess. Stir well, filter, and wash  $\text{AgCl}$  ppt thoroly. To combined filtrate and washings add 5 mL ferric indicator and few mL  $\text{HNO}_3$ , and titr. excess Ag with thiocyanate std soln to permanent light brown. From mL  $\text{AgNO}_3$  used, calc. % Cl.

**Volumetric Method II (25)****3.075****Reagents**

(a) *Potassium iodide std soln.*—1 mL = 1 mg Cl. Weigh 4.6824 g pure (ACS) KI, dried to const wt at 105–150°, dissolve in H<sub>2</sub>O, and dil. to 1 L.

(b) *Silver nitrate stock soln.*—Approx. 0.3*N*. 1 mL = ca 10 mg Cl. Dissolve 48 g AgNO<sub>3</sub> in H<sub>2</sub>O, filter, and dil. to 1 L.

(c) *Silver nitrate std soln.*—Dil. 100 mL reagent (b) to ca 900 mL and adjust by stdzg against reagent (a) so that 1 mL = 1 mg Cl.

(d) *Chloride-free starch indicator.*—For each 100 mL final soln take 2.5 g sol. starch and make to paste with cold H<sub>2</sub>O. Stir out lumps, add 25–50 mL more cold H<sub>2</sub>O, and stir or shake 5 min. Centrf., decant, and discard liq. Repeat extn 3 times and finally transfer residue to flask contg proper amt of boiling H<sub>2</sub>O. Stir again, heat to bp, cover with small beaker, and cool under tap, shaking occasionally.

(e) *Dilute sulfuric acid.*—Add 35 mL H<sub>2</sub>SO<sub>4</sub> to each 1 L H<sub>2</sub>O, boil 5–10 min, and cool to room temp.

(f) *Iodine indicator.*—To ca 20 g I in 500 mL g-s bottle add 400 mL dil. H<sub>2</sub>SO<sub>4</sub>, (e), and shake 10 min. Decant and discard first soln, since it may contain iodides. Repeat process and store soln in small g-s bottles.

(g) *Potassium permanganate soln.*—Dissolve 60 g KMnO<sub>4</sub> in 400 mL warm H<sub>2</sub>O (ca 50°) and dil. to 1 L.

(h) *Potassium sulfate-copper sulfate mixture.*—Thoro mix 16 parts K<sub>2</sub>SO<sub>4</sub> and 1 part CuSO<sub>4</sub>·5H<sub>2</sub>O.

(i) *Wash soln.*—Mix 980 mL H<sub>2</sub>O and 20 mL HNO<sub>3</sub>.

**3.076****Determination**

(Caution: See 51.019, 51.026, and 51.080.)

Weigh sample contg 10–40 mg Cl into beaker. (If >4 g is taken, use proportionately more HNO<sub>3</sub> and KMnO<sub>4</sub> soln.) Add 10 mL 0.3*N* AgNO<sub>3</sub> and stir until sample is thoro soaked, adding little H<sub>2</sub>O or warming if necessary. Add 25 mL HNO<sub>3</sub>, stir, add 5 mL KMnO<sub>4</sub> soln, and stir until frothing stops. Place mixt. in H<sub>2</sub>O bath or on hot plate and keep just below bp. Stir, and wash down sides of beaker at intervals with min. H<sub>2</sub>O. After 20 min, or when reaction stops, add addnl KMnO<sub>4</sub> soln, little at time, until color begins to fade slowly. Dil. to ca 125 mL with boiling H<sub>2</sub>O and heat 10 min longer. (Beaker may stand in bath or on hot plate until ready to filter.)

Filter while hot thru Whatman No. 5, or equiv. paper, with suction as follows: Place disk of 30-mesh stainless steel wire gauze or No. 40 filter cloth in bottom of 3" (7.6 cm) Hirsch funnel. Fold 9 cm paper over bottom of No. 11 rubber stopper, shaping it to funnel by making 9–10 folds up side of stopper. Place paper in funnel and apply strong suction. Wet paper and keep wet while fitting into funnel so as to avoid double thicknesses of paper. Wash paper thoro, first with H<sub>2</sub>O and then with wash soln. Discard washings and rinse out flask. Decant thru filter and transfer ppt and sample residue to filter. If filtrate is not turbid, or if it is only slightly opalescent, wash ppt thoro, applying wash soln very gently, but keeping strong suction on filter. If combined filtrate and washings are clear, test for Ag. If turbid, reheat and pass thru filter, repeating until clear, and finally wash as above. If filtrate does not give definite test for Ag, repeat detn on smaller sample.

Place paper and contents in Kjeldahl flask and add such amts of K<sub>2</sub>SO<sub>4</sub>-CuSO<sub>4</sub> mixt. and H<sub>2</sub>SO<sub>4</sub> as would be appropriate for protein detn on same kind and amt of sample, and digest similarly. (For 2 g grass, 8 g sulfate mixt. and 20 mL acid are enough.) When digest is cool, add 175 mL H<sub>2</sub>O, boil 5–10 min, and cool to room temp. Titr. the Ag<sub>2</sub>SO<sub>4</sub> in Kjeldahl flask with KI

std soln, using 5 mL starch indicator and 30 mL I indicator. (Add latter just before titrn.) Rinse neck of flask after each addn of KI when near end point and titr. until soln stays blue after shaking. If <30 mg Cl is present, add starch and I solns at beginning. If larger but unknown amt is present, add 2 mL starch and 10 mL I indicator at beginning and titr. until end point approaches. Shake vigorously to coagulate ppt, add rest of starch and I solns, and proceed to end point. If known large amt is present, titr. to within 2 mL of end point, shake as above, add indicator reagents, and continue titrn. If end point is overrun, add 5 mL std AgNO<sub>3</sub> soln and titr. again.

Blank detns are not necessary after testing reagents. If blank made by using pure sugar as sample is >0.05 mg, examine filter paper, distd H<sub>2</sub>O, and various reagents for Cl.

**Fluoride****Potentiometric Method (26)—Official First Action**

(Rinse all plastic and glass containers with HCl (1+3) and H<sub>2</sub>O before use. Perform analyses in laboratory free from F; prep. samples in another laboratory.)

**3.077****Principle**

F is extd from dry, pulverized foliage with HNO<sub>3</sub> followed by aq. KOH. Slurry is adjusted to pH 5.5, and complexing agent and background F are added. Potential is measured with ion selective electrode and compared against calibration curve. Method is applicable to 10–2000 µg F/g dry wt leaf tissue not exposed to unusual amts of Al or other F-binding agents; it is not applicable to insol. inorg. F or F in org. combinations. Between-laboratory precision of individual analyses is ±20% at 30 ppm F; ±10%, ≥100 ppm F. Accuracy is 90–100%.

**3.078****Apparatus**

*Electrometer.*—Range ±200 mv with readability of 0.1 mv (Model 701 or 701A digital pH/mv meter, Orion Research Inc., or equiv.) or expanded scale pH meter with mv mode of operation, with F ion selective electrode (No. 94–09 single electrode, Orion Research Inc., or equiv.) and reference electrode (No. 90–01 single junction, Orion Research Inc., or equiv.). Check system at intervals to assure adherence to following performance criteria: Using technic of 3.080, system should reach equilibrium (ΔE < 0.2 mv/min) within 5 min with each F working std soln, checked in following sequence: 0.1, 0.2, 0.5, 2.0, and 10.0 ppm F. Replicate std solns should differ by ≤1 mv. Calibration curve should be linear between 0.2 and 10.0 ppm and slope should be 57±2 mv per 10-fold change in F concn. If any parameter is not obtained, check electrodes, reagents, and electrometer. Maintain temp. control to ±1°.

**3.079****Reagents**

(Store all solns in tightly closed, plastic bottles.)

(a) *Nitric acid.*—(1) 10*N*.—Add 63 mL HNO<sub>3</sub> to H<sub>2</sub>O, cool, and dil. to 100 mL. (2) 0.2*N*.—Dil. 5.0 mL 10*N* to 250 mL. (3) 0.05*N*.—Dil. 5.0 mL 10*N* to 1 L.

(b) *Potassium nitrate soln.*—0.4*M*. Dissolve 4.0 g KNO<sub>3</sub> in H<sub>2</sub>O and dil. to 100 mL.

(c) *Sodium citrate soln.*—0.8*M*. Dissolve 58.8 g Na citrate·2H<sub>2</sub>O in 200 mL H<sub>2</sub>O, adjust to pH 5.5 by dropwise addn of 10*N* HNO<sub>3</sub>, using pH meter, and dil. to 250 mL with H<sub>2</sub>O.

(d) *Sodium citrate with fluoride soln.*—0.4*M* citrate with 1 ppm F. Dil. 125 mL 0.8*M* Na citrate soln and 25.0 mL 10 ppm F std soln to 250 mL with H<sub>2</sub>O.

(e) *Fluoride std solns.*—(1) *Stock soln.*—100 ppm F. Dry ca 1 g NaF 2 hr at 110°. Accurately weigh 0.221 g NaF, dissolve in

**Table 3:01 Preparation of Working Standard Solutions**

Concn, ppm	mL soln to be dild to 100 mL			
	0.4M KNO <sub>3</sub>	0.8M Na citrate	100 ppm F soln	10 ppm F soln
10	10.0	5.0	10.0	0.0
2	10.0	5.0	2.0	0.0
0.5	10.0	5.0	0.0	5.0
0.2	10.0	5.0	0.0	2.0
0.1	10.0	10.0 mL Na citrate soln contg 1 ppm F		

H<sub>2</sub>O, and dil. to 1 L. (2) *Intermediate soln.*—10 ppm F. Dil. 10.0 mL stock soln to 100 mL with H<sub>2</sub>O. (3) *Working solns.*—Prep. as in Table 3:01 in 100 mL vol. flasks. Prep. 0.2 and 0.1 ppm solns fresh as needed.

**3.080****Preparation of Calibration Curve**

Place 25.0 mL 0.1 ppm F working std soln into plastic container contg stirring bar. Insert electrodes ca 12 mm into soln and stir mag. Record mv readings at 1 min intervals until change is <0.2 mv/min. Remove electrodes, blot lightly with absorbent paper, and repeat reading with 0.2, 0.5, 2.0, and 10.0 ppm std solns. Place electrodes in 0.2 ppm std soln until samples are analyzed. (10 ppm std soln may be omitted if samples are known to contain <400 ppm F.)

Plot potential (mv) on vertical arithmetic axis and F concn (μg/mL; ppm) on horizontal (logarithmic) axis of 2-cycle semilog graph paper.

**3.081****Preparation of Sample**

Dry foliage 48 hr at 80°. Grind to pass No. 40 sieve and store in clean, dry, tightly closed plastic bottle. Rotate bottle to mix sample thoroly before removing aliquots.

**3.082****Determination**

Accurately weigh ca 0.25 g powd sample, and place in 75–100 mL wide-mouth plastic container. Add 20 mL 0.05N HNO<sub>3</sub> and place on rotating shaker or stir mag. 20 min. Add 20 mL 0.1N KOH (5.6 g/L) and agitate addnl 20 min. Add 5.0 mL Na citrate soln contg 1 ppm F, adjusted to pH 5.5, and 5.0 mL 0.2N HNO<sub>3</sub>.

(Samples may be stored covered ≤4 hr at this point.) Det. mv readings as in 3.080 and prep. calibration curve before and after each series of samples.

If sample series contains mixt. of high and low samples, make preliminary estn of F content after 2 min. Then det. F concn in samples contg <40 ppm first and in higher ones last.

$$\text{ppm F } (\mu\text{g/g}) = (C - 0.10) \times 50/w,$$

where *C* = ppm F from curve; 0.10 = ppm background F in final soln; 50 = mL final soln; and *w* = g sample.

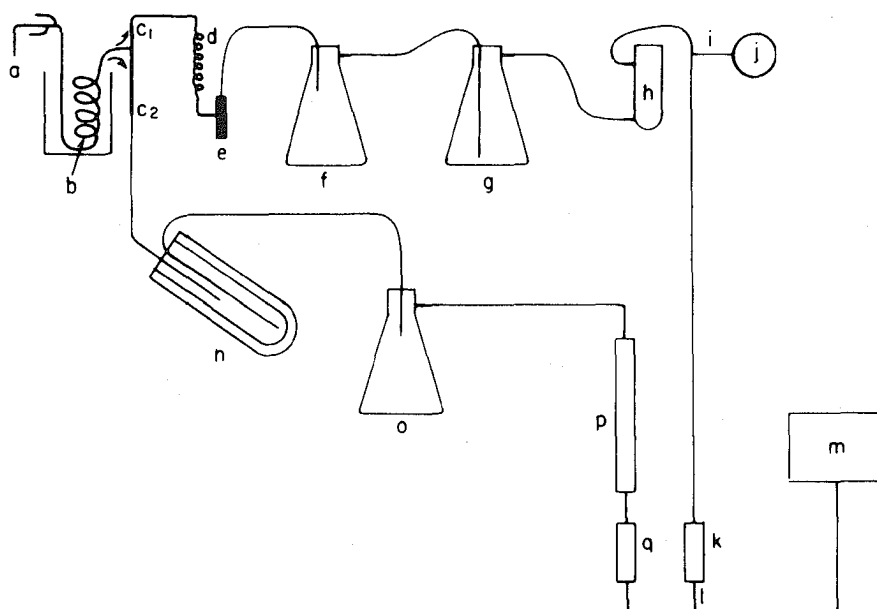

**ASTM-Intersociety Committee-AOAC  
Semiautomated Method (27)**

**Official First Action****3.083****Principle**

Dried and ground plant material is ashed, fused with alkali, and dild to vol. In case of leaf samples, F on external surfaces may be washed off sep. Digest and H<sub>2</sub>SO<sub>4</sub> are pumped into microdistn app. maintained at 170°. Stream of air carries acidified sample to fractionation column where F and H<sub>2</sub>O are distd into condenser, and condensate passes into small collector. Distillate is mixed continuously with alizarin F blue-lanthanum reagent, colored stream passes thru tubular flowcell of colorimeter, and *A* is measured at 624 nm.

Interfering metal cations and inorg. phosphate are not distd, and org. substances are destroyed by ashing. Interference from remaining volatile inorg. anions is reduced with high concn acetate buffer with some reduction in sensitivity. Very large amts solid matter, particularly silicates, retard distn. Therefore, smallest sample consistent with obtaining suitable amt F should be used. Conditions must be carefully controlled, since accurate results depend upon obtaining same degree of efficiency of distn from samples as from std F solns used for calibration.

Acid concn during distn is maintained at const value by using specific amts CaO and NaOH for ashing and fusion and HClO<sub>4</sub> for transfer of fused samples. Any marked change in vac. (>0.2" Hg or 5 torr) over short time indicates either leak or block in system. Distil at same vac. each day and maintain proper ratio between air flow on line drawing liq. and solid wastes from distn coil and on line drawing HF and H<sub>2</sub>O vapor from distn unit

**FIG. 3:02—Schematic drawing of air flow system used in semiautomated analysis for fluoride**

(Fig. 3:02). Adjust flowmeters to keep this ratio const and to maintain higher vac. on HF line,  $C_1$ , so that min. is diverted to waste line.

Method can detect  $0.1 \mu\text{g F/mL}$ . Normal range is  $0.1\text{--}4.0 \mu\text{g F/mL}$ . Dil. higher concns with  $\text{NaOH-HClO}_4$  soln, (k). If digested samples routinely exceed  $4.0 \mu\text{g/mL}$ , modify anal. portion of pump manifold to reduce sensitivity, or use smaller sample aliquot (preferred). Most accurate results are obtained in middle or upper part of calibration curve. For example, to decrease sensitivity, pump sample thru  $0.081''$  tube ( $2.5 \text{ mL/min}$ ) and dil. with  $\text{H}_2\text{O}$  pumped thru  $0.065''$  tube ( $1.6 \text{ mL/min}$ ) before sample enters distn app. Total vol. sample and diluent should approx. original vol. used ( $4.1 \text{ mL/min}$ ).

If air-borne contaminants are present in laboratory, attach small drying bulb contg  $\text{CaCO}_3$  granules to air inlet tube of microdistn unit. Teflon distn coil of microdistn unit must be cleaned periodically to avoid accumulation of solids which reduce sensitivity.

Coefficient of variation of  $20\text{--}100 \text{ ppm F}$  is generally  $\leq 10\%$ . Samples with large amt of Si (orchard grass) or Al may present special difficulties. There should be no significant deviation from linearity with different amts sample and with different amts added F.

### 3.084

### Apparatus

(Cat. Nos refer to current Technicon equipment, except where indicated. Corresponding equipment under previous Cat. Nos is satisfactory.)

(a) *Automatic analyzer*.—(Fig. 3:03) AutoAnalyzer, Technicon Instruments Corp., or equiv. (1) *Sampler*.—Sampler IV with rotary stirrer and  $8.5 \text{ mL}$  plastic sample cups. Use 10 or 20/hr cam with 1:3 sample-to-wash ratio (No. 171-A015-07). (2) *Colorimeter*.—With  $15 \text{ mm}$  tubular flowcell and  $624 \text{ nm}$  interference filter (199-A001-05). (3) *Recorder*.—Ratio type with  $2\text{--}100 \text{ mv}$  full scale range (011-A115-01). (4) *Multichannel proportioning pump and manifold cartridge*.—With assorted pump tubes,

nipple connectors, and glass connectors (pump III 113-A014-08; cartridge 116-8340-01).

(b) *Pulse suppressors*.—For sample and color reagent streams. Coil  $10'$  length of  $0.035''$  id Teflon std tubing around  $2.5''$  diam. tube. Force outlet end into short length of  $0.045''$  id Tygon tubing which is then sleeved with piece of  $0.081''$  Tygon tubing. Slip sleeved end over "h" fitting which joins sample and reagent streams. (Pulse suppressor included with manifold cartridge.)

(c) *Voltage stabilizer*.—161-A007-01 (also part of 199-A001-05).

(d) *Rotary vacuum and pressure pump*.—With continuous oiler (Gast No. 0211-V45F-G8CX pump, available from SGA Scientific, Inc.).

(e) *Microdistillation apparatus*.—(Fig. 3:04) Major components are (Cat. Nos. are those of SGA Scientific, Inc., except as noted): (1) Bottom only of jacketed  $1 \text{ L}$  resin reaction flask with conical flange (JR-5130), modified by evacuating space between inner and outer walls and sealing off port (a); (2) resin reaction flask top with conical flange (JR-7935) modified to have one  $\frac{1}{8}$  29/42 center joint and four  $\frac{1}{8}$  24/40 side joints; (3) resin reaction flask clamp (JR-9210); (4) variable high-speed stirrer (S-6362) (d); (5) stainless steel, heavy duty stirrer stuffing box with  $\frac{1}{8}$  29/42 and shredded Teflon packing (JS-1160 and JS-3050); (6)  $10 \text{ mm}$  diam. stainless steel stirrer rod with propeller to fit stuffing box; (7) thermometer-thermoregulator, range  $0\text{--}200^\circ$  (T-5715) (c); (8) electronic relay control box (T-5905); (9) low drift immersion heater,  $750 \text{ watts}$  (H-1265) (b); (10)  $30'$  length coil of flexible Teflon TFE tubing,  $\frac{1}{8}''$  id,  $3/16''$  od,  $0.030''$  wall, on rigid support of such diam. that completed coil will fit into resin reaction flask (avoid kinking of tubing) (e); (11) 2 flowmeters with ranges  $0\text{--}1$  and  $0\text{--}5 \text{ L/min}$ , both with needle valve controls (Dwyer Instrument, Inc., PO Box 373, Michigan City, IN 46360); (12) vac. gage with range  $0\text{--}10'' \text{ Hg}$  or  $0\text{--}254 \text{ torr}$  (mm Hg); (13) fractionation column of borosilicate glass (g; see also Fig. 3:05; 116-0635); (14) distillate collector (B2 fitting; 116-011-01); (15)  $\text{H}_2\text{O}$ -jacketed condenser (116-0156-01) (h); (16) Dow-Corning 200 fluid ( $100 \text{ centistokes}$  at  $25^\circ$ ) (f); and (17) condenser (116-0181-01) (j).

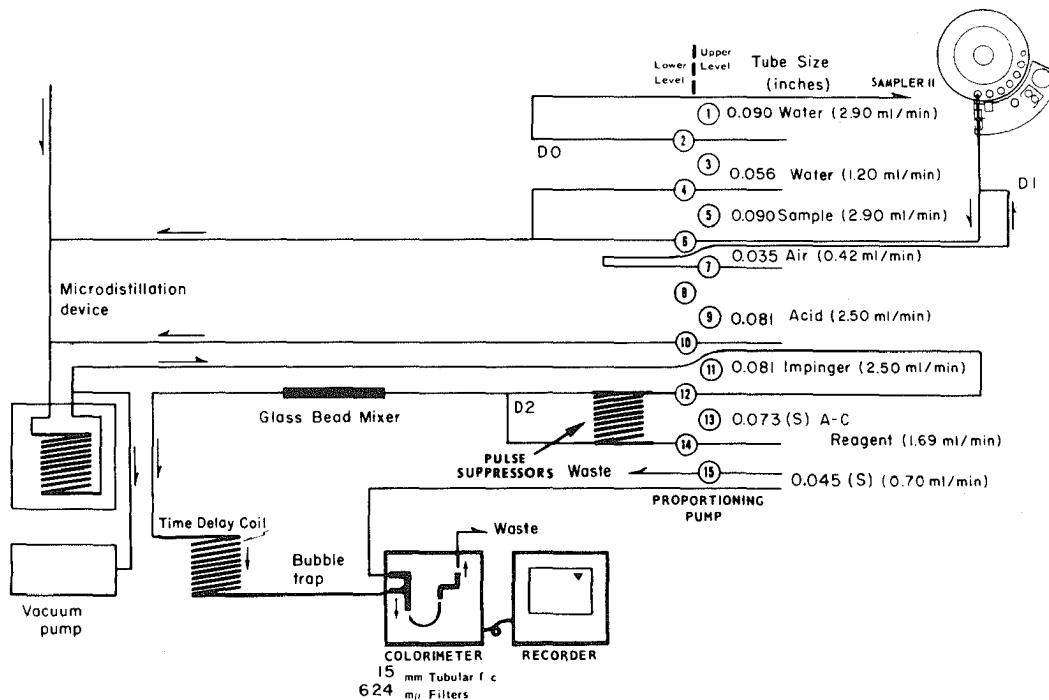

FIG. 3:03—Flow diagram for semiautomated analysis for fluoride

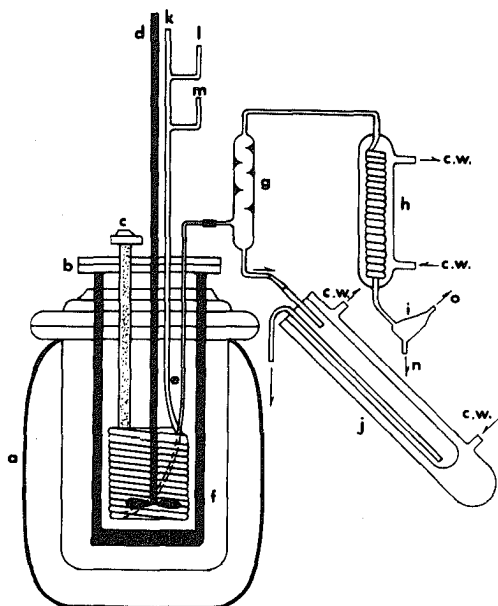

FIG. 3:04—Schematic drawing of microdistillation apparatus

(f) *Crucibles*.—Inconel, Ni, or Pt, 40–50 mL.

(g) *Air flow system*.—(Fig. 3:02) Draw air thru air inlet tube, (a), before Teflon microdistn coil, (b). Air sweeps thru (b) to fractionation column, and is diverted into 2 channels. In channel  $c_1$ , air passes thru  $H_2O$ -jacketed condenser, (d), sample trap, (e), to waste bottle, (f). Air then passes thru  $\frac{1}{8}$ " id glass tube directed against surface of  $H_2SO_4$  in waste bottle, (g). Partially dehydrated air passes thru gas drying tower, (h), contg 450 g indicating silica gel. Emerging air passes thru T-tube, (i), connected to vac. gage, (j) (0–10" Hg or 0–254 torr), thru flowmeter, (k) (0–5 L/min), thru T-tube, (l), and then to vac. pump, (m).

In channel  $c_2$ , air passes thru  $H_2O$ -jacketed waste trap, (n), to waste bottle, (o). Air leaving waste bottle flows thru drying bulb, (p), filled with indicating silica gel, and the dry air then passes thru flowmeter, (q) (0–1 L/min). Air stream then connects thru T-tube, (l), with air from first channel.

### 3.085

### Reagents

(Caution: See 51.028 and 51.030.)

(Deionized  $H_2O$  may be used. CaO for ashing and NaOH for fusion must be low in F.)

(a) *Sulfuric acid*.—(1+1). Mix 500 mL  $H_2SO_4$  with 500 mL  $H_2O$  and cool before use.

(b) *Acetate buffer*.—2.14M (pH 4.0). Dissolve 60 g  $NaOAc \cdot 3H_2O$  in 500 mL  $H_2O$ , add 100 mL HOAc, and dil. to 1 L with  $H_2O$ . Stable at 25°.

(c) *Alizarin fluorine blue color reagent stock soln*.—0.01M. Suspend 0.9634 g reagent (alizarin complexone, alizarin complexan; 3-amino-ethylalizarin-*N,N*-diacetic acid; Burdick & Jackson Laboratories, Inc.) in ca 100 mL  $H_2O$  in 250 mL vol. flask. Add 2 mL  $NH_4OH$  and shake until completely dissolved. Add 2 mL HOAc and dil. to vol. with  $H_2O$ . Stable indefinitely at 4°.

(d) *Lanthanum nitrate stock soln*.—0.02M. Dissolve 8.6608 g  $La(NO_3)_3 \cdot 6H_2O$  in  $H_2O$  and dil. to 1 L in vol. flask.

(e) *Wetting soln*.—30% soln (w/v) polyoxyethylene lauryl ether in  $H_2O$  (Brij-35, Technicon No. T21-0110). Soln is stable at 25°.

(f) *Working reagent*.—Mix, in order listed, 300 mL acetate

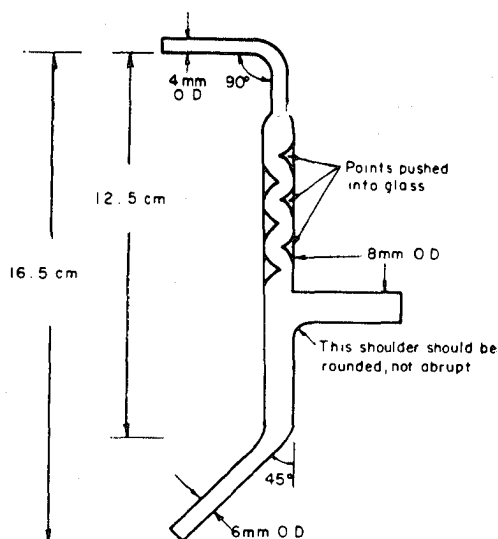

FIG. 3:05—Microdistillation column

buffer, 244 mL  $H_2O$ , 300 mL acetone, 100 mL *tert*-butanol, 36 mL alizarin fluorine blue stock soln, 20 mL  $La(NO_3)_3$  stock soln, and 2 mL wetting soln. Unused reagent is stable 7 days at 4°. Before using reagent, place under vac. 10 min to remove air bubbles from soln.

(g) *Fluoride std solns*.—(1) *Stock soln*.—100  $\mu g$  F/mL. Dissolve 0.2207 g NaF in  $H_2O$  and dil. to 1 L. (2) *Working solns*.—Prep. 7 solns contg 0.2, 0.4, 0.8, 1.6, 2.4, 3.2, and 4.0  $\mu g$  F/mL. Before dilg to vol., add 6 g NaOH and 20 mL 70%  $HClO_4$  for each 100 mL final working soln so that stds have same composition as sample solns. Dil. with  $H_2O$  only for analysis of  $H_2O$  samples or air samples absorbed in  $H_2O$ . Store working solns at 4° in polyethylene bottles; stable in presence of NaOH.

(h) *EDTA solns*.—1%. Dissolve 1 g  $Na_4EDTA$  in 99 mL  $H_2O$ . Prep. 0.05% and 0.01% solns by mixing 5 mL 1% soln with 95 mL  $H_2O$  and 1 mL 1% soln with 99 mL  $H_2O$ , resp.

(i) *Phenolphthalein soln*.—Dissolve 1 g phthln in 50 mL absolute alcohol or isopropanol and add 50 mL  $H_2O$ .

(j) *Detergent*.—Alconox (Alconox, Inc., 215 Park Ave S, New York, NY 10003); available from laboratory supply firms.

(k) *Sodium hydroxide-perchloric acid soln*.—Dissolve 6 g NaOH in  $H_2O$ , add 40 mL 70%  $HClO_4$  (1+1), and dil. to 100 mL with  $H_2O$ . Use to dil. samples when F in unknown sample exceeds std curve.

### 3.086

### Preparation of Sample

(a) *Leaves*.—If it is necessary to remove surface F, wash sample with aq. soln contg 0.05% detergent and 0.05%  $Na_4EDTA$  in polyethylene container 30 sec with gentle agitation. Remove, drain 3–4 sec, and rinse 10 sec in each of 3 beakers of  $H_2O$ . Discard solns after use.

(b) *Fresh plant tissues*.—Dry 24–48 hr in 80° forced-draft oven, and grind as in (c).

(c) *Dry plant tissues*.—Grind in semimicro Wiley mill to pass No. 40 sieve, and store in plastic container.

### 3.087

### Ashing and Fusion

Accurately weigh 0.1–2.0 g well mixed dried plant tissue into crucible. Add  $100 \pm 10$  mg low-F CaO, enough  $H_2O$  to make loose slurry, and 4 drops phthln soln. Mix thoroly with polyethylene policeman. Final mixt. should be purple and remain purple during evapn to dryness.

Place crucible on cold hot plate and under IR lamp. Evap. under lamp to dryness, turn on hot plate, and char 1 hr. Transfer crucible to furnace at 600° and ash 2 hr. (*Caution:* To avoid flaming, place crucibles at front of furnace with door open ca 5 min to further char samples; then reposition in furnace.)

Remove crucibles, add  $3.0 \pm 0.1$  g NaOH pellets, and replace in furnace with door closed to melt NaOH. (*Caution:* Avoid creeping of molten NaOH.) Remove crucibles individually and swirl to suspend particulate matter until melt is partially solidified. Let cool until addn of small amt H<sub>2</sub>O does not cause spattering. Wash down inner walls with 10–15 mL H<sub>2</sub>O. Suspend melt with polyethylene policeman and transfer with H<sub>2</sub>O to plastic tube graduated at 50 mL. Rinse crucible with 20.0 mL 70% HClO<sub>4</sub> (1+1), add rinse to tube, and dil. to 50 mL with H<sub>2</sub>O. Solns can be stored at this point if tightly capped.

Analyze blank contg all reagents with each set of ca 10 samples.

Clean crucibles as soon as possible after each use. Boil Inconel crucibles 1 hr in 10% NaOH soln. Rinse with hot tap H<sub>2</sub>O, detergent, and then distd H<sub>2</sub>O. Immerse crucibles which held samples contg  $>100 \mu\text{g F}$  in 4*N* HCl 45 min before boiling in NaOH soln. Perform blank analyses on these crucibles before addnl use to check for contamination. Scrub Ni and Pt crucibles with detergent and hot H<sub>2</sub>O and rinse thoroly with H<sub>2</sub>O. Briefly rinse crucibles which held samples contg  $>100 \mu\text{g F}$  in 4*N* HCl before rinsing with H<sub>2</sub>O.

### 3.088

#### Analytical System

Place F std solns, ashed and fused samples, or impinged air samples in 8.5 mL plastic cups in sample module. Actuate sampler and pump from cup at net rate of 2.48 mL/min with air segmentation of 0.42 mL/min after sampler crook, and pump into microdistn device thru sample inlet (*l*, Fig. 3:04), using 0.051" id Teflon tubing. Pump H<sub>2</sub>SO<sub>4</sub> at 2.5 mL/min thru acid inlet (*m*, Fig. 3:04). Cool and discard acid and solids. Pump distillate from sample trap at 2.0 mL/min thru 0.051" Teflon tubing, add color reagent at 1.69 mL/min, and mix in 4" length of 1/8" id glass tubing packed with pieces of 20 mesh broken Pyrex glass. Pass colored stream thru time delay coil of 15' of 0.035" Teflon spaghetti tubing, thru debubbler fitting where small portion of stream and bubbles are removed to waste bottle at rate of 0.70 mL/min, and thru 15 mm tubular flowcell of colorimeter. *A* is measured at 624 nm and plotted on recorder. Lag time from sampling to appearance of peak is ca 5 min. Time between samples is 6 min with sampling rate of 10/hr and 3 min at 20/hr.

### 3.089

#### Start-Up

Turn on H<sub>2</sub>O to condenser and cooling jacket. Turn on colorimeter. Engage manifold on proportioning pump and start pump. Turn on stirring motor of microdistn unit, vac. pump adjusted for full vac., and heater of microdistn unit. Connect lines to H<sub>2</sub>SO<sub>4</sub>, color reagent, and H<sub>2</sub>O bottles. Sampling tube of sampler unit should be in H<sub>2</sub>O reservoir. Equilibrate app. until silicone oil in microdistn unit reaches  $170 \pm 2^\circ$ . Check that all connections are secure. Adjust distn flowmeter (*k*, Fig. 3:02) to 2.5–3 L/min; adjust waste flowmeter (*q*) to 0.3 L/min. Distillate should now fill sample trap. Readjust flowmeter (*k*) to give reading on vac. gage of 5–6" Hg (127–150 torr). (Satisfactory setting for app. must be detd by trial and error. Once detd, use each day.) No air bubbles should be in anal. system beyond point where color reagent and distillate streams are joined. Turn on recorder, adjust baseline to desired level, and run several min to assure that all components are operating properly. Baseline should be reasonably smooth and straight.

Transfer F std solns to 8.5 mL plastic cups and place in sampler. Sep. last std soln from sample solns with cup of H<sub>2</sub>O. Program sampler for 10 samples/hr (90 sec sampling period, 270 sec washout period) or 20 samples/hr (45 sec sampling period, 135 sec washout period).

Prep. std curve, 3.092, before and after each day's set of samples. Net *A* of 0.7–0.9 should be obtained with std soln contg  $4 \mu\text{g F/mL}$ . *A* of each std soln should be reproducible within 10% from day to day and std curve should be linear from 0.2 to  $\geq 3.2 \mu\text{g/mL}$ .

### 3.090

#### Shut-Down

Turn off chart recorder. Disconnect H<sub>2</sub>SO<sub>4</sub> line and place in H<sub>2</sub>O. Disconnect color reagent line and place in 0.01% EDTA soln ca 1 min; then transfer line to H<sub>2</sub>O and let H<sub>2</sub>O pass thru system ca 5 min. Clean Teflon distn coil as in 3.091(a). Turn off heater and stirrer of microdistn unit. Turn off vac. pump. Release pump tube manifold. Turn off H<sub>2</sub>O to condenser and cooling trap.

### 3.091

#### Maintenance

(a) *Cleaning of Teflon distillation coil.*—(After use with samples contg particulate matter.) Briefly insert Tygon tube connected to air inlet line of microdistn unit into 0.01% EDTA soln. After all deposited material has been removed, wash with 3–4 five mL portions distd H<sub>2</sub>O.

(b) *Pump tubes.*—Replace after 200 working hr or earlier if hard and inflexible or flattened. Always leave in relaxed position when not in use. Remove dirt and grease from pump plates and rollers after each day of use.

(c) *Indicating silica gel.*—Regenerate when ca 2/3 has lost normal blue color.

(d) *Cleaning tubing.*—Clean tubing contg reagent after each daily run with 0.01% EDTA soln followed by distd H<sub>2</sub>O.

(e) *Monthly checks.*—Oil proportioning pumps monthly. Check gain on recorder monthly and adjust.

### 3.092

#### Calibration and Standards

Before and after each day's set of samples, prep. std curve by transferring aliquots of each working std soln to 8.5 mL sample cups and proceed with analysis. Draw straight line connecting baseline before and after analysis. Record *A* of each peak and subtract *A* of baseline at peak. Plot net *A* against  $\mu\text{g F/mL}$ .

### 3.093

#### Calculations

$$\text{ppm F in sample} = (F \times V \times D) / W,$$

where *F* =  $\mu\text{g F/mL}$  sample from std curve; *V* = mL sample, usually 50; *D* = diln factor used only when *F* of sample exceeds std curve = mL final vol. to which original aliquot was dild with NaOH-HClO<sub>4</sub> soln, (k)/mL original aliquot taken; and *W* = g sample taken for analysis.

### 3.094

#### Check Procedure

(a) *Contamination.*—Perform reagent and equipment blank with crucibles and reagents but without sample to detect contamination from previous samples, contaminated furnace, and reagents. Blank values  $>5 \mu\text{g F}$  are evidence of contamination. Perform 2 blank detns with each set of 20–40 samples. Usual blanks are 1–3  $\mu\text{g}$ .

(b) *Recoveries.*—Occasionally add known amts F std soln from microburet to aliquots of low F tissue. Recovery of added F should be  $100 \pm 10\%$ . Low values indicate loss of F, possibly during pretreatment; high values indicate contamination.

(c) *Linearity*.—Occasionally analyze different amts (0.1–2.0 g) plant sample contg 50–65 ppm F. Linear relationship should exist between F found and amt tissue taken. Nonlinearity may indicate that some component of tissue is retarding distn or interfering with color development.

(d) *Calibration curves*.—Prep. at least twice daily.

### 3.095

#### Trouble Shooting

(a) *Irregular baseline*.—May result from: (1) excessive pulse pressures—check for faulty pump tubes, absence of surge suppressors, or improperly made or placed suppressors; (2) air bubbles in flowcell—check for absence of debubbler bypass, blockage in reagent pump tube, or periodic emptying of sample trap (latter results if air flow to distn trap becomes too great); (3) excessive  $\text{H}_2\text{SO}_4$  carryover—check for too high temp. in oil bath, improper  $\text{H}_2\text{SO}_4$  concn, or too high vac. on system; (4) air flow imbalances—check flowmeter settings, trapped air in tubing, or leak or block in system; (5) high F content in samples (baseline may not return to normal between samples)—dil. or check sampling speed and sample-to-wash ratio.

(b) *Irregular peaks*.—Asymmetrical or double peaks or peaks with shoulders may result from: (1) baseline irregularities; (2) interfering substances from sample or impure reagents; (3) inadequate buffer concn; or (4) excessive amts solids in distn coil. Presence or accumulation of solids may be due to insufficient flow of  $\text{H}_2\text{SO}_4$ , too large sample, excess CaO or NaOH in sample, inadequate suspension of particles in samples, or lack of proper air segmentation in sample tubing.

(c) *Poor reproducibility*.—Check for: improper sample pickup; faulty pump tubes; inadequate washing of distn coil between samples; large deviations in acid concn, temp., or air flow in distn coil; or changes in vac. on waste system.

### Selenium

#### 3.096 ★ Gravimetric Method (28)—Official Final Action ★

(Applicable to materials contg >2 ppm Se)

See 3.073, 11th ed.

#### Fluorometric Method (29)—Official Final Action

(Caution: See 51.008, 51.019, 51.026, and 51.028.)

### 3.097

#### Apparatus

(a) *Micro-Kjeldahl flasks*.—30 mL Pyrex, ca 170 mm total length with  $\frac{5}{8}$  12/18 outer joint at mouth.

(b) *Air condensers*.—10 × 140 mm Pyrex tubes with  $\frac{5}{8}$  12/18 inner joint.

(c) *Micro-Kjeldahl digestion unit with glass fume duct*.—Fit rack to hold flasks and attached air condensers in nearly upright position during early stages of digestion. Use in fume hood.

(d) *Fluorometer*.—Capable of illuminating sample at 369 nm and measuring fluoresced light at 525 nm. Turner Associates, 2524 Pulgas Ave, Palo Alto, CA 94303, Model 110 or 111 filter fluorometer equipped with std lamp No. 110-850, primary filter No. 7-60, and secondary filter No. 58 is satisfactory. Model 430 spectrofluorometer set to above wavelengths is also satisfactory.

### 3.098

#### Reagents

(Use deionized  $\text{H}_2\text{O}$  distd in glass for prepg solns and dilns.)

(a) *Nitric acid*.—Redistd in glass.

(b) *Hydroxylamine-ethylenediaminetetraacetic acid soln*.—Add ca 20 mL  $\text{H}_2\text{O}$  to 1.9 g EDTA (acid form). Slowly add ca 5N  $\text{NH}_4\text{OH}$  with stirring until EDTA just dissolves. Some excess

$\text{NH}_4\text{OH}$  is not harmful. Dissolve 6 g  $\text{NH}_4\text{OH} \cdot \text{HCl}$  in 100 mL  $\text{H}_2\text{O}$ . Combine solns and dil. to 250 mL with  $\text{H}_2\text{O}$ .

(c) *Cresol red indicator*.—Dissolve 0.1 g cresol red in 10 mL  $\text{H}_2\text{O}$  and 1 drop 50% NaOH soln. Dil. to 50 mL with  $\text{H}_2\text{O}$ .

(d) *Selenium std soln*.—0.3  $\mu\text{g}$  Se/mL. Add 10 mL  $\text{HNO}_3$  to 30.0 mg Se (purity  $\geq 99\%$ ) and warm to dissolve. Dil. to 100 mL with  $\text{H}_2\text{O}$ , mix well, and transfer exactly 1 mL to micro-Kjeldahl flask. Add 2 mL 70%  $\text{HClO}_4$  and 1 glass bead. Boil gently to  $\text{HClO}_4$  fumes and cool. Add 1 mL  $\text{H}_2\text{O}$  and 1 mL  $\text{HCl}$  (1+4); heat 30 min in boiling  $\text{H}_2\text{O}$  bath. Transfer to 1 L vol. flask and dil. to vol. with ca 1N  $\text{HCl}$ . Store in all-glass container. Soln is stable several months at room temp.

(e) *Decalin*.—Eastman Kodak No. 1905 decahydronaphthalene, or equiv.

(f) *2,3-Diaminonaphthalene (DAN) soln*.—Prep. soln in semi-darkened room or in room with only yellow light at time of detn. Protect from light and prep. fresh for each set of detns. Add 50 mL ca 0.1N  $\text{HCl}$  to 0.05 g DAN (available from ICN-K&K Laboratories, Inc.). Place in 50°  $\text{H}_2\text{O}$  bath in dark 15 min. Cool to approx. room temp. and ext twice with 10 mL decalin, shaking vigorously each time and discarding decalin. Filter thru paper satd with  $\text{H}_2\text{O}$ . For >8 detns, prep. larger amt.

### 3.099

#### Preparation of Samples

Grind air-dried samples to pass No. 18 or finer sieve. Cut fresh or wet samples finely with scissors or knife, or grind in food chopper to assure representative sample.

Some plants (e.g., *Astragalus bisulcatus*, *A. racemosus*, *Stanleya bipinnata*, and *Oenopsis condensata*) contain Se in volatile form that is lost during drying. Analyze these plants without drying. With usual agricultural crops, this is not a problem if drying is performed at 60–70°.

### 3.100

#### Preparation of Fluorometric Blanks and Standard

(a) *Blank*.—Place 1 mL  $\text{H}_2\text{O}$  in micro-Kjeldahl flask. (For samples contg <0.1 ppm, carry 10 mL  $\text{HNO}_3$  as blank thru entire detn.)

(b) *Std*.—Place 1.0 mL std Se soln in micro-Kjeldahl flask.

Add 2 mL 70%  $\text{HClO}_4$  to each flask and continue as in detn, beginning "Mix contents of flasks . . ."

### 3.101

#### Determination

(a) *Samples containing 4 or more ppm selenium*.—Weigh  $\leq 1$  g sample (air-dried wt basis) contg  $\leq 0.4 \mu\text{g}$  Se into micro-Kjeldahl flask. Add 1 glass bead, previously cleaned with  $\text{HNO}_3$ . Add 10 mL  $\text{HNO}_3$  and let stand at room temp.  $\geq 4$  hr. (Use 5 mL  $\text{HNO}_3$  for samples <0.5 g.) Affix air condenser and place flask in nearly upright position on micro-Kjeldahl digestion unit. Heat ca 15 min with low flame and then increase heat until  $\text{HNO}_3$  condenses in lower part of condenser. Heat 10 min longer, turn off burner, and let cool 5 min. Wash down sides of flask with 2 mL 70%  $\text{HClO}_4$  thru air condenser. Swirl flask and continue refluxing 15 min. Remove condenser and continue heating, drawing off fumes in fume duct, until  $\text{HClO}_4$  fumes appear and then 15 min longer. Cool, add 1 mL  $\text{H}_2\text{O}$ , and again heat to  $\text{HClO}_4$  fumes and 1–2 min longer. Cool, and add 1 mL  $\text{H}_2\text{O}$ .

Mix contents of flasks and add 1 mL  $\text{HCl}$  (1+4) to each. Place in boiling  $\text{H}_2\text{O}$  bath 30 min. Cool to ca room temp.

To each flask add 5 mL  $\text{NH}_4\text{OH}$ -EDTA soln and 2 drops cresol red indicator. Neutze to yellow with ca 5N  $\text{NH}_4\text{OH}$  and add  $\text{HCl}$  (1+4) to orange-pink. From this point, perform all operations in semidarkened room or room with yellow light only. Prep. DAN soln, add 5 mL to each flask, and dil. to neck with ca 0.1N  $\text{HCl}$ . Mix and place in 50°  $\text{H}_2\text{O}$  bath in dark 25 min.

★ Surplus method—see inside front cover.

Remove flasks from H<sub>2</sub>O bath and cool to ca room temp. in pan of H<sub>2</sub>O. Pour solns into 125 mL separators with Teflon stopcocks and contg 10.0 mL decalin. Shake vigorously  $\geq 30$  sec, let stand ca 1 min, and drain and discard lower layer. Wash decalin twice by shaking vigorously  $\geq 15$  sec with 25 mL ca 0.1N HCl. (VirTis, Rt 208, Gardiner, NY 12525, Extractomatic shaker with 100 mL separators may be substituted. When used, shake ext 5 min and wash 1 min periods.) Transfer decalin layer to 12 mL centrf. tubes and centrf. 2 min at moderate speed. Pour decalin soln into fluorometer tubes, zero fluorometer against decalin, and read all tubes at 525 nm within 5 min. Correct std and unknown readings for blank.

ppm Se = 0.3  $\times$  sample reading/std reading  $\times$  g sample.

(b) *Samples containing less than 4 ppm selenium.*—Proceed as in (a) thru second par. Dil. digest to adequate vol. and take aliquot contg ca 0.3  $\mu$ g Se for detn. Alternatively, digest sample in 10 vols HNO<sub>3</sub> 2 hr on steam bath. Dil. to definite vol., and carry appropriate aliquot thru detn. Latter method is especially applicable when proper sampling requires large sample. Do not dil. decalin soln contg piasselenol, as this introduces errors.

### Boron (30)—Official Final Action

#### Quinalizarin Method

#### 3.102

#### Reagents

(a) *Dilute sulfuric acid.*—0.36N. Dil. 10 mL H<sub>2</sub>SO<sub>4</sub> to 1 L.

(b) *Calcium hydroxide saturated soln.*—Filter before use.

(c) *Quinalizarin soln.*—Dissolve 45 mg quinalizarin in 1 L 95–96% H<sub>2</sub>SO<sub>4</sub>.

(d) *Boron std soln.*—0.5 mg B/mL. Dissolve 2.860 g H<sub>3</sub>BO<sub>3</sub> and dil. to 1 L with H<sub>2</sub>O. Prep. working stds by further diln with H<sub>2</sub>O.

#### 3.103

#### Determination

Place 1.00–2.00 g dry, ground plant material in Pt or SiO<sub>2</sub> dish. Add 5 mL satd Ca(OH)<sub>2</sub> soln and dry at 105°. Carefully volatilize over burner, ash in furnace 1 hr at 600°, and cool. Add exactly 10 or 15 mL 0.36N H<sub>2</sub>SO<sub>4</sub>, break up ash with glass rod, stir gently, and filter. Transfer 2 mL filtrate to colorimeter tube, add an exact amt (e.g., 15 mL) quinalizarin reagent, stopper, and mix by swirling gently. Let stand at room temp. 24 hr (or until both unknowns and stds have cooled to same temp.). Shake tube again immediately before reading in photoelec. colorimeter (620 nm filter).

Adjust colorimeter to 100% *T* with blank soln prepd as above but using 2 mL H<sub>2</sub>O in place of sample soln. Prep. std curve with series of stds contg 0.5–10  $\mu$ g B/mL.

### OTHER CONSTITUENTS

#### Sugars (31)—Official Final Action

#### 3.104

#### Preparation of Solution

(a) *General method.*—Prep. fresh sample as in 3.002(b). Pour alc. soln thru filter paper or extn thimble, catching filtrate in vol. flask. Transfer insol. material to beaker, cover with 80% alcohol, warm on steam bath 1 hr, let cool, and again pour alc. soln thru same filter. If second filtrate is highly colored, repeat extn. Transfer residue to filter, let drain, and dry. Grind residue so that all particles will pass thru 1 mm sieve, transfer to extn thimble, and ext 12 hr in Soxhlet app. with 80% alcohol. Dry residue and save for starch detn. Combine alc. filtrates and dil. to vol. at definite temp. with 80% alcohol.

For dried materials, grind samples finely, and mix well. Weigh

sample into beaker, and continue as above, beginning "... cover with 80% alcohol, ..."

(b) *Applicable when starch is not to be determined.*—Prep. fresh sample as in 3.002(b), but boil on steam bath 1 hr. Decant soln into vol. flask, and comminute solids in high-speed blender with 80% alcohol. Boil blended material on steam bath 0.5 hr, cool, transfer to vol. flask, dil. to mark with 80% alcohol at room temp., filter, and take aliquot for analysis.

Grind dry material to pass No. 20 sieve or finer, transfer weighed sample to vol. flask, and add 80% alcohol and enough CaCO<sub>3</sub> to neutze any acidity. Boil 1 hr on steam bath, cool, adjust vol. at room temp. with 80% alcohol, filter, and take aliquot for analysis.

#### 3.105

#### Clarification with Lead

Place aliquot alc. ext in beaker on steam bath and evap. off alcohol. Avoid evapn to dryness by adding H<sub>2</sub>O if necessary. When odor of alcohol disappears, add ca 100 mL H<sub>2</sub>O and heat to 80° to soften gummy ppts and break up insol. masses. Cool to room temp. and proceed as in (a) or (b):

(a) Transfer soln to vol. flask, rinse beaker thoroly with H<sub>2</sub>O, and add rinsings to flask. Add enough satd neut. Pb(OAc)<sub>2</sub> soln to produce flocculent ppt, shake thoroly, and let stand 15 min. Test supernate with few drops of the Pb(OAc)<sub>2</sub> soln. If more ppt forms, shake and let stand again; if no further ppt forms, dil. to vol. with H<sub>2</sub>O, mix thoroly, and filter thru dry paper. Add enough solid Na oxalate to filtrate to ppt all the Pb, and refilter thru dry paper. Test filtrate for presence of Pb with little solid Na oxalate.

(b) Add twice min. amt of satd neut. Pb(OAc)<sub>2</sub> soln required to cause complete pptn, as found by testing portion of supernate with few drops dil. Na oxalate soln. Let mixt. stand only few min; then filter into beaker contg estd excess of Na oxalate crystals. Let Pb ppt drain on filter and wash with cold H<sub>2</sub>O until filtrate no longer gives ppt in oxalate soln. Assure excess of oxalate by testing with 1 drop Pb(OAc)<sub>2</sub>. Filter and wash pptd Pb oxalate, catching filtrate and washings in vol. flask. Dil. to vol. with H<sub>2</sub>O and mix.

#### 3.106

#### Clarification with Ion-Exchange Resins (32)

Place aliquot alc. ext, 3.104, in beaker and heat on steam bath to evap. alcohol. Avoid evapn to dryness by adding H<sub>2</sub>O. When odor of alcohol disappears, add ca 15–25 mL H<sub>2</sub>O and heat to 80° to soften gummy ppts and break up insol. masses. Cool to room temp. Prep. thin mat of Celite on filter paper in buchner or on fritted glass filter and wash until H<sub>2</sub>O comes thru clear. Filter sample thru Celite mat, wash mat with H<sub>2</sub>O, dil. filtrate and washings to appropriate vol. in vol. flask, and mix well.

Place 50.0 mL aliquot in 250 mL erlenmeyer; add 2 g *Amberlite IR-120(H)* analytical grade cation (replaced by REXYN 101(H) resin, Fisher Scientific Co.) and 3 g *Duolite A-4(OH)* anion ion exchange resins. Let stand 2 hr with occasional swirling. Take 5 mL aliquot deionized soln and det. reducing sugars as glucose as in 31.053.

#### Glucose

#### 3.107

#### Micro Method—Official Final Action

See 31.053.

#### Fructose (33)—Official Final Action

#### 3.108

#### Reagents

(a) *Glucose oxidase preparation.*—Add slowly, stirring constantly, 100 mL H<sub>2</sub>O to 5 g glucose oxidase prepn ("DeeO L-750" code 4633000, Miles Laboratories, Inc., 1127 Myrtle St,

Elkhart, IN 46514). Stir ca 1 min and centr. or filter to obtain clear soln. Add ca 1 mL  $\text{CHCl}_3$  and refrigerate. Soln is stable  $\geq 1$  month.

(b) *McIlvaine's citrate-phosphate buffer*.—Dissolve 214.902 g  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  and 42.020 g citric acid in  $\text{H}_2\text{O}$  and dil. to 1 L.

### 3.109

#### Determination

To suitable aliquot add  $\frac{1}{4}$  its vol. of buffer to give pH ca 5.8. Add 30% as much glucose oxidase prepn as estd glucose content (for 500 mg glucose add 150 mg glucose oxidase, *i.e.*, 3 mL soln), and few drops 30%  $\text{H}_2\text{O}_2$  (omit if Somogyi method is to be used in detn). Let stand overnight at room temp.

Det. fructose by Somogyi micro method, 31.053, or by Munson-Walker method, 31.038–31.039, using Table 3:02. Check equivs in range of interest, using pure fructose as std, and correct as necessary.

**Table 3:02 Abbreviated Munson and Walker Table for Calculating Fructose**

(From *Official and Tentative Methods of Analysis*, AOAC, 5th Ed., 1940)

Cuprous Oxide mg	Fructose mg	Cuprous Oxide mg	Fructose mg
10	4.5	300	148.6
50	23.5	350	174.9
100	47.7	400	201.8
150	72.2	450	229.2
200	97.2	490	253.9
250	122.7	—	—

### 3.111 ★ Quisumbing-Thomas Method ★

See 31.048–31.049, 11th ed.

#### Sucrose—Official Final Action

### 3.112 Hydrochloric Acid Inversion

Using aliquot of cleared soln, 3.105, proceed as in 7.079.

### 3.113 Invertase Inversion

(a) *For plants giving hydrolysis end point within 2 hours*.—Pipet aliquot of cleared soln, 3.105, into 400 mL Pyrex beaker and make slightly acid to Me red with HOAc. Add 3 drops 1% soln of *Wallerstein invertase scales*. Let mixt. stand at room temp. 2 hr. Add reagents as in 31.035, and det. reducing power. Calc. results as invert sugar. Deduct reducing power of original soln, also expressed as invert sugar, and multiply difference by 0.95.

(b) *For plants giving slower hydrolysis end point*.—Place aliquot of soln, 3.105, in small vol. flask. Make slightly acid to Me red with HOAc. Add 3 drops 1% soln of *Wallerstein invertase scales* and few drops toluene. Stopper flask and let stand overnight or longer at room temp. Dil. to vol. with  $\text{H}_2\text{O}$  and use aliquot for reducing power as above.

#### Starch (34)—Official Final Action

### 3.120

#### Reagents

(a) *Iodine-potassium iodide soln*.—Grind 7.5 g I and 7.5 g KI with 150 mL  $\text{H}_2\text{O}$ , dil. to 250 mL, and filter.

(b) *Alcoholic sodium chloride soln*.—Mix 350 mL alcohol, 80 mL  $\text{H}_2\text{O}$ , and 50 mL 20% NaCl soln, and dil. to 500 mL with  $\text{H}_2\text{O}$ .

(c) *Alcoholic sodium hydroxide soln*.—0.25N. Mix 350 mL alcohol, 100 mL  $\text{H}_2\text{O}$ , and 25 mL 5N NaOH, and dil. to 500 mL with  $\text{H}_2\text{O}$ .

(d) *Dilute hydrochloric acid*.—0.7N. Dil. 60 mL HCl to 1 L with  $\text{H}_2\text{O}$ .

(e) *Somogyi phosphate sugar reagent*.—Dissolve 56 g anhyd.  $\text{Na}_2\text{HPO}_4$  and 80 g Rochelle salt in ca 1 L  $\text{H}_2\text{O}$ , and add 200 mL 1.00N NaOH. Then slowly add, with stirring, 160 mL 10%  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  soln. Dissolve 360 g anhyd.  $\text{Na}_2\text{SO}_4$  in this soln, transfer to 2 L vol. flask, and add exactly 200 mL 0.1N  $\text{KIO}_3$  soln (3.5667 g/L). Dil. to vol., mix well, let stand several days, and filter thru dry paper into dry flask, discarding first 50 mL filtrate. Store reagent at 20–25°. It is 0.01N with respect to  $\text{KIO}_3$ ; 5.00 mL is equiv. to 10 mL 0.005N  $\text{Na}_2\text{S}_2\text{O}_3$ .

Det. glucose factor of reagent as follows: Accurately weigh 150 mg NBS glucose SRM into 1 L vol. flask, dissolve in  $\text{H}_2\text{O}$ , dil. to vol., and mix well. Transfer 5 mL aliquot to 25 × 200 mm Pyrex test tube, add exactly 5 mL Somogyi reagent, stopper with size 00 crucible, and heat (together with several blanks contg 5 mL  $\text{H}_2\text{O}$  and 5 mL reagent) exactly 15 min in boiling  $\text{H}_2\text{O}$  bath. Tit. as in detn. From difference between blank and std titrns, calc. mg glucose equiv. to 1 mL exactly 0.005N  $\text{Na}_2\text{S}_2\text{O}_3$ . Effective range for detn is 0.05–1.0 mg glucose in 5 mL aliquot.

(f) *Sodium thiosulfate std soln*.—0.005N. Dissolve 2.73 g  $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 2 L. Stdze daily as follows: Add 1 mL KI soln, (g), and 3 mL 1.5N  $\text{H}_2\text{SO}_4$  to 5 mL Somogyi sugar reagent. Let stand 5 min, and tit. with  $\text{Na}_2\text{S}_2\text{O}_3$  soln, adding starch indicator, (h), just before end point.

(g) *Potassium iodide soln*.—2.5%. Stabilize with little  $\text{Na}_2\text{CO}_3$ .

(h) *Starch indicator*.—Make 1.5 g sol. starch into paste with few mL  $\text{H}_2\text{O}$ , and add slowly, with stirring, to 300 mL boiling  $\text{H}_2\text{O}$ .

### 3.121

#### Determination

Select sample as in 3.001, remove all foreign matter, dry, and grind to pass No. 80 sieve. Accurately weigh 0.1–1.0 g powd sample contg ca 20 mg starch into 25 × 150 mm Pyrex test tube. Add ca 200 mg fine sand and 5 mL  $\text{H}_2\text{O}$ , and mix well with stirring rod to wet sample. Heat tube in boiling  $\text{H}_2\text{O}$  bath 15 min to gelatinize starch. Cool to room temp., and place in 22–25° bath. Add 5 mL 60%  $\text{HClO}_4$  rapidly with const agitation. Grind tissue against lower wall of tube with stirring rod for approx.

★ Surplus method—see inside front cover.

min at time. Repeat grinding frequently during 30 min; then without delay, transfer quant. to 100 mL vol. flask with  $H_2O$ . Add 3 mL 5% *uranyl acetate soln* to ppt protein, dil. to vol. with  $H_2O$ , mix well, and centr. portion of mixt. Pipet 10 mL clear supernate into 25 × 150 mm test tube. Add ca 100 mg Celite, 5 mL 20% NaCl soln, and 2 mL I-KI reagent, and mix well. Let stand overnight, centr., and decant.

Wash starch-I ppt by suspending it in 5 mL alc. NaCl soln, centr., and decant. Add 2 mL alc. NaOH soln to packed ppt. Gently shake and tap tube until ppt is no longer blue. (Do not use stirring rod; allow ample time for complex to decompose.) Wash walls of tube with 5 mL alc. NaCl soln, centr. liberated starch, and wash with 5 mL alc. NaCl soln as before. Add 2 mL 0.7*N* HCl to ppt. Stopper tube loosely with size 00 crucible, and heat 2.5 hr in boiling  $H_2O$  bath. (Bath should have cover with holes to accommodate tubes; holes not occupied by tubes must be covered.) Cool, and transfer quant. to 25 mL vol. flask. Add drop phenol red, 50.008, and neutze with 1*N* NaOH. Discharge color with 0.1*N* oxalic acid, dil. to vol., and mix well. Transfer 5 mL aliquot to 25 × 200 mL Pyrex test tube, add exactly 5 mL Somogyi reagent, and stopper tube with size 00 crucible. Heat together with several blanks contg 5 mL  $H_2O$  and 5 mL Somogyi reagent in vigorously boiling  $H_2O$  bath exactly 15 min. Remove tube from bath and cool to 25–30°. Add 1 mL 2.5% KI soln down wall of tube without agitation and then add 3 mL 1.5*N*  $H_2SO_4$  rapidly with agitation. After all  $Cu_2O$  dissolves, titr. soln with 0.005*N*  $Na_2S_2O_3$ , adding starch indicator, (h), just before end point is reached. Treat blank solns similarly.

$$\% \text{ Starch} = [50(\text{mL blank} - \text{mL sample}) \times 0.90/\text{mg sample}] \times (N/0.005) \times G \times 100,$$

where 50 = diln factor, 0.90 = factor glucose to starch, *N* = actual normality  $Na_2S_2O_3$  soln, and *G* = mg glucose equiv. to 1 mL 0.005*N*  $Na_2S_2O_3$ .

### Lignin (35)—Official Final Action

#### Direct Method

#### 3.122

#### Preparation of Sample

Grind sample in mill to pass No. 80 sieve and dry at 105°. Ext weighed sample (5–10 g) 30 hr in Soxhlet app. with alcohol-

benzene soln (32 parts alcohol and 68 parts benzene by wt). Dry material in oven to free it from solvs and place in flask of suitable size. Add 150 mL  $H_2O$ /g sample, and reflux 3 hr. Filter mixt. while still hot, preferably thru weighed fritted glass crucible, and transfer extd material to flask. Add 1% HCl (111 g concd HCl + 3890 mL  $H_2O$ ) in proportion of 150 mL acid soln/g plant material, and reflux 3 hr. Filter mixt. while still hot thru fritted glass crucible previously used, wash with  $H_2O$  until acid-free, dry at 105°, and weigh. Calc. % total loss due to successive extn with alcohol-benzene soln, hot  $H_2O$ , and 1% HCl. (With samples not especially rich in carbohydrates and proteins, extn with hot  $H_2O$  may be omitted.)

#### 3.123

#### Apparatus

App., Fig. 3:06, consists of: (1) 1.5 L bottle, *A*, to which is attached by 2-hole rubber stopper 250 mL dropping funnel, *C*, having lower end of stem bent as illustrated and placed close to bottom of *A*; (2) Drechsel gas-washing bottle, *D*; (3) 3 Pyrex test tubes, 38 × 300 mm diam., *G*, *G'*, *G''*, connected in parallel by device, *O*, and immersed in wooden box, *L*, filled with crushed ice, *H*; and (4) bottle contg  $H_2O$  for absorption of excess HCl, *K*. *G*, *G'*, and *G''* are provided with 2-hole rubber stoppers; glass tube with right angle bend extends thru 1 hole nearly to bottom of test tube, and similar tube extending ca 10 mm into test tube passes thru other hole. Rubber connections and stopcocks for regulating flow of gas are provided as indicated in diagram. *A* is filled with ca 500 mL  $H_2SO_4$  and *C* with HCl; HCl flowing thru stopcock *B* into *A* generates HCl gas, which is dried by  $H_2SO_4$  in *D*, and flows into *G*, *G'*, and *G''* contg samples and fuming HCl reagent.

#### 3.124

#### Reagent

*Fuming hydrochloric acid.*—(Caution: See 51.031.) Density 1.212–1.223 at 15°. To 500 g NaCl in 1 L g-s Pyrex distg flask, add cold soln of 250 mL  $H_2O$  in 450 mL  $H_2SO_4$ . Connect side tube of distg flask to glass tube passing thru  $H_2SO_4$  wash bottle, and connect outlet tube of  $H_2SO_4$  wash bottle to another glass tube, immersed in flask contg 3 L HCl. Surround flask contg HCl with crushed ice. Heat distg flask with small flame and pass HCl gas into acid soln until it attains sp gr of 1.212–1.223 at 15°. Keep

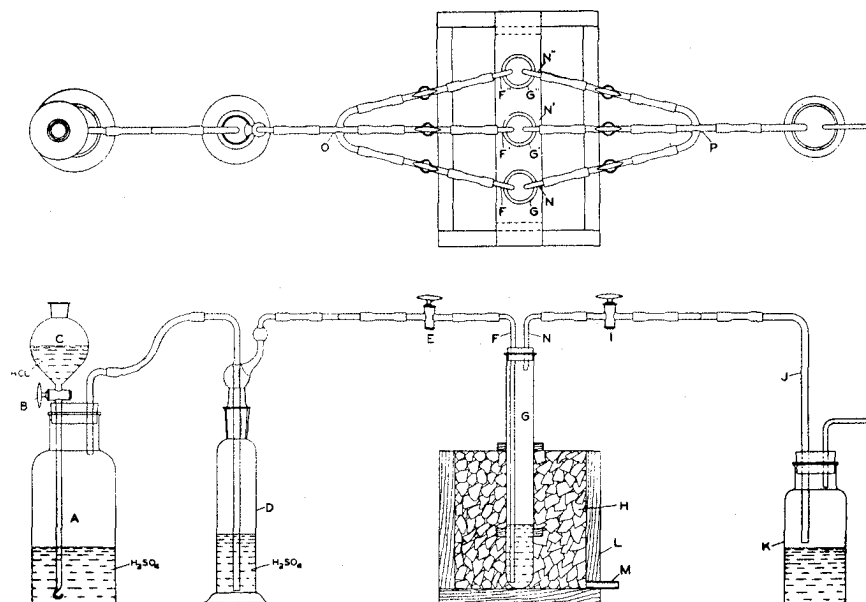

FIG. 3:06—Apparatus for determining lignin

reagent refrigerated at  $\leq 0^\circ$ . If only few detns are to be made, prep. correspondingly smaller amt.

### 3.125

#### Determination

Weigh three 1 g samples of extd and dried sample in weighing bottle and place in 3 large test tubes, *G*, *G'*, and *G''*. Add 20 mL of the reagent to each tube, using this acid to wash down any particles clinging to sides. When all material is wet with reagent, add addnl 30 mL reagent. Add ca 3 drops *capryl alcohol* to minimize foaming. Place test tubes, *G*, *G'*, and *G''*, in wooden box, *L*, and surround with crushed ice. Lubricate tubes *F*, *F'*, and *F''* with drop of glycerol so that they move easily thru holes in rubber stoppers. Lead dry HCl gas from generator into reaction mixts thru tubes *F*, *F'*, and *F''* (*F'* and *F''* are shown in top view), which reach nearly to bottom of tubes *G*, *G'*, and *G''*. Regulate flow of gas thru reaction mixts in *G*, *G'*, and *G''* by stopcocks shown in top view, continuing passage of gas 2 hr. (At first rather slow stream of gas passes in, but during last 15 min, flow is fairly rapid.)

After reaction period, discontinue flow of gas, and disconnect long tubes *F*, *F'*, and *F''* and outlet tubes of test tubes *G*, *G'*, and *G''* from *O* and *P*. Pull tubes *F*, *F'*, and *F''* just above surface of reaction mixt., and close with short pieces of rubber tubing having one end plugged with short piece of glass rod. Similarly close off outlet tubes, *N*, *N'*, and *N''*. Place tubes contg reaction mixt. in cold room or refrigerator ( $8-10^\circ$ ) 24 hr.

Transfer contents of *G*, *G'*, and *G''* to 1 L erlenmeyers, taking care to remove any material adhering either to inside or outside of tubes *F*, *F'*, and *F''*. Dil. reaction mixts to 500 mL with  $H_2O$ . Connect flasks to reflux condensers and boil 1 hr. Prep. 3 gooches in usual manner, dry at  $105^\circ$ , and weigh. Ignite one of weighed crucibles, *X*, over Bunsen burner, cool in desiccator, and reweigh. Let contents of flasks cool to room temp. and filter thru weighed gooches. Wash ppts collected in gooches with hot  $H_2O$ , dry at  $105^\circ$ , and weigh in weighing bottles. Ignite crude lignin in crucible *X* over Bunsen flame and det. wt ash. Place one of other 2 gooches in wide-neck Kjeldahl flask and det. % N in crude lignin as in 2.057. If methoxyl in lignin is to be detd, collect ppt from one of flasks in dried ( $105^\circ$ ) fritted glass crucible and proceed as in 47.050.

Wt lignin = wt crude lignin - wt ash - wt crude protein ( $N \times 6.25$ ).

Calc. % lignin in original dry unextd material.

### 3.126 Indirect Method (36)

(Caution: See 51.086.)

Ext 1 g sample with alcohol-benzene (1+2) 4 hr in Soxhlet or comparable app. (extn vessel may be either coarse porosity Alundum or paper thimble, closed at top with filter paper or plug of cotton). Wash sample in thimble with suction, using 2 small portions alcohol followed by 2 small portions ether. Heat at  $45^\circ$  in nonsparking oven to drive off ether, and transfer sample to 250 mL wide-mouth erlenmeyer. Add 40 mL 1% soln of *pepsin* in 0.1N HCl, wetting sample well by adding small portion reagent, stirring or shaking thoroly, and finally washing down sides of flask with remaining soln. Incubate at  $40^\circ$  overnight.

Add 20-30 mL hot  $H_2O$  and filter, using filter stick. (Filter sticks are made with Pyrex fritted glass disk, 30 mm diam., medium porosity. Thin layer of pre-ashed diat. earth (Hyflo Super-Cel, or similar filter-aid) is sucked onto disk from  $H_2O$  suspension. This is usually enough for easy filtration; if not, add extra Super-Cel to material being filtered. Some sticks filter slowly with some samples. It is advisable to obtain more than needed and discard slow-filtering ones. It is convenient to arrange filter sticks in set of 12 attached to vac. manifold by rubber tubing.)

Repeat washing twice and then wash residue into flask by forcing 7-8 mL 5% (w/w)  $H_2SO_4$  downward thru filter stick, using air pressure. Wash stick further with the  $H_2SO_4$ , finally adding enough to bring total vol. to ca 150 mL. Reflux vigorously on hot plate 1 hr, adding  $H_2O$  occasionally to maintain original vol. Filter off acid. Wash residue with three 20-30 mL portions hot  $H_2O$ , two 15-20 mL portions alcohol, and two 15 mL portions ether. Leave vac. on few min to dry residue, and transfer from stick to flask by tapping and brushing. Heat to drive off any residual ether. If disk formed upon drying is difficult to break up into finely divided state (sometimes in case of immature plant samples), disperse residue in ether in flask and then boil off ether on steam bath. Add 20 mL 72% (w/w)  $H_2SO_4$  at  $20^\circ$  to residue and hold 2 hr at  $20^\circ$ , stirring occasionally. Add 125 mL  $H_2O$ , filter, wash once with 20 mL hot  $H_2O$ , and filter again. Wash residue from filter stick and reflux as before 2 hr, using 150 mL 3% (w/w)  $H_2SO_4$ . Filter residue onto gooch with asbestos pad and wash with hot  $H_2O$  until acid-free. Dry at  $105-110^\circ$  and det. lignin by loss in wt on ignition at  $600^\circ$ .

## PIGMENTS

### Chlorophyll—Official Final Action

#### Photoelectric Colorimetric Method for Total Chlorophyll Only (37)

### 3.127

#### Apparatus

(a) *Mortar and pestle*.—Deep glass mortar ca 10 cm id with well-defined lip.

(b) *Photoelectric colorimeter*.—Calibrate for chlorophyll, using plant ext as in 3.129 and light filters with max. *T* near 660 nm. (Combination of Corning Glass Works filters CS No. 2-60 and 1-58 (Glass No. 2408 and 3965, resp.) is suitable.)

(c) *Wash bottles*.—Type fitted with rubber bulb, permitting operation with one hand.

(d) *High-speed blender*.—Waring Blendor, or equiv.

### 3.128

#### Reagents

(a) *Acetone*.—(1) Undild acetone and (2) 85% aq. soln by vol. Com. acetone, tech. grade, is satisfactory.

(b) *Quartz sand*.—Acid-washed and dried.

### 3.129

#### Determination

(Caution: See 51.004, 51.040, and 51.046.)

Select field material carefully to ensure representative sample. Remove representative portion from field sample, and if fresh, cut finely with hand shears and mix as thoroly as possible. Grind dried material in mill and mix thoroly.

Weigh 1-5 g into mortar and add ca 0.1 g  $CaCO_3$  or  $Na_2CO_3$ . Macerate tissue with pestle, add quartz sand, and grind short time; then add 85% acetone, little at time, and continue grinding until tissue is finely ground. Transfer mixt. to funnel, filter with suction, and wash residue with 85% acetone. Return residue to mortar with more 85% acetone and grind again. Filter and wash as before. Repeat procedure until tissue is devoid of any green, and washings are colorless. (It is advisable to grind residue at least once with undild acetone and then to add enough  $H_2O$  at end to bring acetone concn to 85%. High-speed blender may be used instead of mortar to macerate and ext tissue (see 3.132), but each investigator should satisfy himself that device used exts tissue completely.) When extn is complete, transfer filtered ext to vol. flask of appropriate size and dil. to vol.

Measure *T* of soln with photoelec. colorimeter, and read amt of chlorophyll present from curve relating *T* and concn. Express

chlorophyll values as mg/g tissue, or in other convenient manner.

Calibrate photoelec. colorimeter as follows: Ext sample of fresh, green leaf material with 85% acetone, filter, wash residue, and dil. ext to vol. as above. Make series of dilns of ext and measure  $T$  of original and of each of dild solns with instrument in same manner as when chlorophyll prepn is being used as calibration std. Transfer aliquot of original ext to ether and evaluate total chlorophyll spectrophtric as in 3.132(b) and (c). From value thus obtained, calc. chlorophyll content of original ext and that of each of dild solns, and construct curve relating concn of chlorophyll with  $T$  or  $A$ .

**Spectrophotometric Method for Total  
Chlorophyll and the  $a$  and  $b$   
Components (38, 39)**

**3.130****Apparatus**

Use app. in 3.127 (except photoelec. colorimeter), plus following:

(a) *Scrubbing tubes for washing ether solns.*—Open tubes ca 20 mm diam. to one end of each of which is sealed tube of smaller diam. drawn to fine jet at lower end.

(b) *Spectrophotometer.*—Capable of isolating spectral region of ca 3 nm near 660 nm with negligible stray radiation. Tubulated cells with tightly fitting glass stoppers are recommended for work with ether.

**3.131****Reagents**

Those listed in 3.128 and following:

*Ether.*—Com. grade is satisfactory without further purification.

**3.132****Determination**

(Wash glassware with concd  $\text{Na}_3\text{PO}_4$  soln to remove traces of acid that may decompose chlorophyll.)

(a) *Extraction of chlorophyll from tissue.*—Select and prep. sample as in 3.129. Disintegrate weighed portion (2–10 g, depending on chlorophyll content) of fresh plant tissue in blender cup that contains ca 0.1 g  $\text{CaCO}_3$ , or by use of mortar as in 3.129. After tissue is thoroly disintegrated, filter ext thru buchner fitted with quant. paper. Wash residue with 85% acetone, 3.128(a), and if necessary, use little ether to remove last traces of pigment. If extn is incomplete, return residue and paper to blender container with more 85% acetone and repeat extn. Filter and wash, as before, into flask contg first filtrate. Transfer filtrate to vol. flask of appropriate size and dil. to vol. with 85% acetone.

Pipet aliquot of 25–50 mL into separator contg ca 50 mL ether. Add  $\text{H}_2\text{O}$  carefully until it is apparent that all fat-sol. pigments have entered ether layer. Drain and discard  $\text{H}_2\text{O}$  layer. Place separator contg ether soln in upper rack of support. Add ca 100 mL  $\text{H}_2\text{O}$  to second separator placed in rack below first. Set scrubbing tube in place, and let ether soln run thru it to bottom of lower separator and rise in small droplets thru the  $\text{H}_2\text{O}$ . When all soln has left upper separator, rinse it and scrubbing tube with little ether added from medicine dropper. Place scrubbing tube in upper separator and exchange its place in support with separator now contg ether soln. Drain and discard  $\text{H}_2\text{O}$  in upper separator, add similar portion of fresh  $\text{H}_2\text{O}$  to lower separator, and repeat washing process. Continue washing ether soln until all acetone is removed (5–10 washings). Then transfer ether soln to 100 mL vol. flask, dil. to vol., and mix.

(b) *Spectrophotometric measurements.*—Add ca teaspoonful (ca 5 mL) anhyd.  $\text{Na}_2\text{SO}_4$  to 60 mL reagent bottle, and fill it with ether soln of pigment. When this soln is optically clear,

pipet aliquot into another dry bottle and dil. with enough dry ether to give  $A$  value of 0.2–0.8 at wavelength to be used. (Most favorable value is near 0.6 at 660 nm, since such soln yields satisfactory value at 642.5 nm.)

Fill 2 clean g-s absorption cells with dry ether from pipet and polish outside surfaces of each, first with cotton wet with alcohol and then with dry cotton. Place cells in instrument, and det. whether each gives same galvanometer deflection. If not, clean again or select cells that do, and do this daily. Empty one cell, fill it with the dried ether soln, and place in instrument. Adjust entrance and exit slits until spectral region isolated is 3–4 nm at 660.0 nm.

Det. whether instrument is in proper adjustment for wavelength by taking  $A$  readings thru soln against solv. at 1 nm intervals from 658 to 665 nm. Highest value should be at 660.0 nm; if not, adjust instrument until it is, or make 660.0 nm readings at wavelength setting that gave highest  $A$ . With grating instrument, apply same correction at 642.5 nm; however, with prism instrument, correction at 642.5 nm must be obtained from wavelength calibration curve for particular instrument in use. Calibrate instrument for wavelength in this way often enough to ensure that it remains in proper adjustment. Det.  $A$  at 660.0 and 642.5 nm (or corrected settings) for each unknown soln.

(c) *Calculation of chlorophyll concentration.*—Calc. total chlorophyll and each of  $a$  and  $b$  components (mg/L) as follows:

$$(1) \text{ Total chlorophyll} = 7.12 A_{660.0} + 16.8 A_{642.5}$$

$$(2) \text{ Chlorophyll } a = 9.93 A_{660.0} - 0.777 A_{642.5}$$

$$(3) \text{ Chlorophyll } b = 17.6 A_{642.5} - 2.81 A_{660.0}$$

**3.133 Supplementary Information**

Factors involved in spectrophtric analysis of chlorophyll system have been discussed in detail by Comar and Zscheile (39). These authors used Beer's law in form:

$$c = (\log_{10} I_0/I) / a \times t \quad [= A/a \times t],$$

where  $I_0$  is intensity of light transmitted by solv.-filled cell;  $I$  is intensity of light transmitted by soln.-filled cell;  $c$  is concn of chlorophyll (g/L);  $a$  is absorptivity;  $t$  is thickness of soln layer in cm, and  $A$  is absorbance.

Since, at given wavelength, observed  $A$  value of soln having 2 components represents sum of  $A$  values of each of components, following equation holds in case of chlorophylls  $a$  and  $b$  at given wavelength:

$$(4) A_{\text{observed}} = A_a + A_b$$

If 1 cm cell is used, this equation may be expressed as:

$$(5) A_{\text{observed}} = a_a c_a + a_b c_b$$

Concns of chlorophylls  $a$  and  $b$  in given ether soln can now be calcd by equation (5) as follows:

(a) Det.  $A$  for soln at 2 different wavelengths (660.0 and 642.5 nm have been found advantageous for this purpose).

(b) From table select proper absorptivities corresponding to wavelengths used.

(c) Substitute observed  $A$  value and absorptivities in equation (5) for each of the 2 wavelengths used as illustrated for 660.0 and 642.5 nm in equations (6) and (7). Solve these 2 equations simultaneously for 2 unknowns, the concns of chlorophylls  $a$  and  $b$ .

$$(6) A_{660.0} = 102 c_a + 4.50 c_b$$

$$(7) A_{642.5} = 16.3 c_a + 57.5 c_b$$

Equations (1), (2), and (3) were derived this way.

Criterion for accuracy of chlorophyll values detd by spectrophtric method is agreement between analytical results detd from measurements at different wavelengths. Comar and Zscheile (39) demonstrated that measurements at 660.0 and

642.5 nm are convenient for routine analysis; however, readings may be made at other wavelengths to check these values. Absorptivities for chlorophylls *a* and *b* in ether soln that may be used for this purpose are presented in Table 3:03.

These values may be used for calcns as follows:

(a) Values for total chlorophyll and % composition may be calcd from *A* at 660.0 and 642.5 nm as described.

(b) Check values for total chlorophyll may be calcd from *A* at intersection points 600.0, 581.0, and 568.0 nm.

(c) Check values for % composition may be calcd from *A* for each of points 613.0 and 589.0 nm in combination with value of total concn obtained from (a) or (b).

**Table 3:03 Absorption constants used in analysis (after Comar and Zscheile (39))**

Wavelength nm	Absorptivities (for Ether Solns)	
	Chlorophyll <i>a</i>	Chlorophyll <i>b</i>
660.0	102	4.50
642.5	16.3	57.5
600.0	9.95	9.95
581.0	8.05	8.05
568.0	7.11	7.11
613.0	15.6	8.05
589.0	5.90	10.3

### 3.134 Carotenes—Official Final Action

See 43.014–43.023.

## TOBACCO

### Moisture (40)—Official Final Action

#### 3.135

#### Apparatus

(a) *Drying oven*.—Forced-draft, regulated to  $99.5 \pm 0.5^\circ$ . Suggested dimensions: 19 × 19 × 19" (48 cm). Approx. oven settings: fresh air intake vent  $\frac{1}{5}$  open; air control damper  $\frac{1}{4}$  open; air exhaust vent  $\frac{1}{3}$  open.

(b) *Moisture dish*.—Al, diam. 45–65 mm, depth 20–45 mm, with tight-fitting cover.

#### 3.136

#### Determination

Accurately weigh ca 5 g sample (ground to pass  $\leq 1$  mm screen) into weighed moisture dish and place uncovered dish in oven.

Do not exceed 1 sample/10 sq in. (650 sq cm) shelf space, and use only 1 shelf. Dry 3 hr at  $99.5 \pm 0.5^\circ$ . Remove from oven, cover, and cool in desiccator to room temp. (ca 30 min). Reweigh to nearest 1 mg and calc. % moisture.

### Chlorides (41)—Official Final Action

#### Potentiometric Method

#### 3.137

#### Reagent

Silver nitrate std soln.—0.1*N*. Stdze against KCl as in detn.

#### 3.138

#### Apparatus

(a) *pH meter*.—Leeds and Northrup, Sumneytown Pike, N Wales, PA 19454, Beckman Instruments, or equiv., equipped with Ag and glass electrodes.

(b) *Buret*.—10 mL, graduated in 0.05 or 0.02 mL, preferably reservoir-type.

#### 3.139

#### Determination

Accurately weigh ca 2 g sample, ground to pass No. 40 sieve, into 250 mL electrolytic beaker. Add 100 mL  $H_2O$ , small amt at first to thoroly wet sample; then remainder. Let stand  $\geq 5$  min at room temp., stirring intermittently. Pipet 5 mL  $HNO_3$  (1+9) into mixt. and insert clean electrodes. Start mag. stirrer and continue stirring thruout titn at rate that produces vigorous agitation without spattering. Tit. with std 0.1*N*  $AgNO_3$  soln to potential previously established as equivalence point. Det. equivalence point potential graphically by making several titrns on one or more tobacco samples. Recheck occasionally, and redet. when either electrode is replaced. Record vol. of titrant and calc.:

$$\% \text{ Cl} = \text{mL } AgNO_3 \times \text{normality} \times 3.5453 / \text{g sample.}$$

### Nitrogen (42)—Official Final Action

#### Kjeldahl Method for Samples Containing Nitrates

(For nitrate-free samples, omit salicylic acid and thiosulfate treatment.)

#### 3.140

#### Reagents

See 2.055 and the following:

(a) *Sodium hydroxide-thiosulfate soln*.—Dissolve 500 g NaOH pellets and 40 g  $Na_2S_2O_3 \cdot 5H_2O$  in  $H_2O$  and dil. to 1 L.

(b) *Indicators*.—(1) Dissolve 1 g Me red in 200 mL alcohol; or (2) prep. mixed indicator by dissolving 0.8 g Me red and 0.2 g methylene blue in 500 mL alcohol.

#### 3.141

#### Apparatus

See 2.056.

#### 3.142

#### Determination

Place weighed sample (1–2 g) in digestion flask. Add vol.  $H_2SO_4$  (contg 2 g salicylic acid/40 mL) corresponding to wt sample (35 mL for 1 g, 40 mL for 2 g for  $NO_3$ -contg samples; 20 and 25 mL, resp., for  $NO_3$ -free samples). Shake until thoroly mixed; let stand  $\geq 30$  min with occasional shaking; then add 5 g  $Na_2S_2O_3 \cdot 5H_2O$ . Shake, let stand 5 min, and heat carefully until frothing ceases. Turn off heat, add 0.7 g HgO (or metallic Hg) and 15 g  $K_2SO_4$ , and boil briskly 1–1.5 hr after soln clears.

Cool, add ca 200 mL  $H_2O$ , cool to ca room temp., and add few Zn granules. Tilt flask and carefully add 50 mL NaOH-thiosulfate soln without agitation. Immediately connect flask to distn bulb on condenser whose tip is immersed in 50 mL std 0.1*N* acid in receiving flask. Then rotate digestion flask carefully to mix contents. Heat until  $\geq 150$  mL distillate collects, and tit. excess acid with std base, using Me red or mixed indicator. Correct for blank detn on reagents.

### Potassium (43)—Official Final Action

#### 3.143

#### Reagents

(a) *Potassium std solns*.—(1) *Stock soln*.—1000 ppm K. See 3.020(a). (2) *Working solns*.—Place 0, 5, 10, 15, 20, 25, and 30 mL stock soln in seven 1 L vol. flasks, add 40 mL 3*N* HCl to each, and dil. to vol. with  $H_2O$ .

(b) *Diatomaceous earth*.—Celite 545, acid-washed.

#### 3.144

#### Apparatus

(a) *Flame photometer*.—Natural gas-air fuel, or equiv., adequate for K analysis.

(b) *Chromatographic tube*.—20 × 150 mm with coarse fritted disk.

## 3.145

**Preparation of Sample Solution**

Accurately weigh ca 0.5 g tobacco dust into ca 40 mL weighing dish. Add ca 1 g Celite and mix intimately with spatula. Transfer quant. thru powder funnel into chromatgc tube. Add addnl Celite thru funnel into tube until 2.5 cm layer accumulates on top of sample-Celite mixt. Compact sample and Celite by tapping tip of tube on table top, and insert tip of tube into neck of 1 L vol. flask. Add 40 mL 3*N* HCl into tube by pipet or dispenser, washing down sides, and let elute into vol. flask. When liq. level reaches top of Celite, add 25 mL H<sub>2</sub>O and let elute. Add second 25 mL portion H<sub>2</sub>O, let elute by gravity, or force thru rapidly with compressed air. Rinse tip of tube into vol. flask, dil. to vol. with H<sub>2</sub>O, and mix well.

## 3.146

**Determination**

Det % *T* for sample eluate and K stds as specified in instruction manual of instrument. See also 3.023.

Prep. calibration curve and det. ppm K of sample from curve.

% K = ppm K × 0.1/g sample.

% K<sub>2</sub>O = ppm K × 0.1205/g sample.

**Glycerol, Propylene Glycol, and Triethylene Glycol in Cased Cigarette Cut Filler and Ground Tobacco (44)—Official First Action**

(Caution: See 51.018 and 51.066.)

## 3.147

**Apparatus**

(a) *Gas chromatograph*.—With programmed temp. oven and W hot wire detector; F&M Model 720 (current models 5700 series; Hewlett-Packard, Inc.), or equiv. Conditions: Detector bridge 140 ma; temps (°): injection 265, detector 280, column 90–240 at 15°/min; He 60 mL/min adjusted, if necessary, to facilitate sepns; attenuation 4, adjusted according to sensitivity to yield peaks of sufficient size for accurate measurement (use same attenuation for all stds and samples); chart speed, 12"/hr.

(b) *Column*.—42 (105 cm) × 3/16" Cu tubing packed with 5% Carbowax 20M-terephthalic acid (TPA) on 60–80 mesh Chromosorb G AW-DMCS (Hewlett-Packard, Inc., No. 8501-6223 or Applied Science Laboratories, Inc., No. 04388). Prep. packing by placing 30.0 g Chromosorb in 500 mL 3-neck flask. Add soln of 1.50 g Carbowax 20M-TPA in 150 mL CHCl<sub>3</sub> and slurry. Remove CHCl<sub>3</sub> under vac. in rotary evaporator and air dry overnight at room temp. Condition new column 2 hr at 240°; then inject three 30 μL samples tobacco ext before analyzing samples. Recondition columns removed from app. before use.

## 3.148

**Reagents**

(a) *Extracting soln*.—Dil. 20.0 mL 1,3-butylene glycol stock std soln, (b), to 2 L with anhyd. MeOH.

(b) *1,3-Butylene glycol stock soln*.—Accurately weigh 20.00 g USP 1,3-butanediol into 100 mL vol. flask and dil. to vol. with anhyd. MeOH.

(c) *Glycerol stock std soln*.—Accurately weigh 10.00 g USP glycerol into 100 mL vol. flask and dil. to vol. with extg soln.

(d) *Propylene glycol stock std soln*.—Accurately weigh 5.00 g USP propylene glycol into 100 mL vol. flask and dil. to vol. with extg soln.

(e) *Triethylene glycol stock std soln*.—Accurately weigh 5.00 g triethylene glycol into 100 mL vol. flask and dil. to vol. with extg soln.

(f) *Humectant std solns*.—Into each of four 100 mL vol. flasks, pipet 1.0, 2.0, 3.0, and 4.0 mL, resp., glycerol, propylene glycol, and triethylene glycol stock std solns. Dil. to vol. with extg soln. Each soln contains (in mg/100 mL):

Soln	Propylene Glycol	Glycerol	Triethylene Glycol
1	50	100	50
2	100	200	100
3	150	300	150
4	200	400	200

## 3.149

**Extraction**

Place 10.00 g sample in 250 mL 3-neck erlenmeyer. Pipet 100 mL extg soln into flask and stopper. Shake mech. 1 hr and let settle few min until supernate is clear. Alternatively, shake mech. 30 min and let stand overnight.

## 3.150

**Determination**

Prime column by injecting two 30 μL aliquots supernate ext. Then alternately inject 30 μL supernate exts and a humectant std soln until all samples and stds have been run, repeating ext injections, if necessary. (Sequence is ext<sub>1</sub>, ext<sub>1</sub>, std<sub>1</sub>, ext<sub>1</sub>, std<sub>2</sub>, ext<sub>2</sub>, std<sub>3</sub>, ext<sub>3</sub>, std<sub>4</sub>, ext<sub>4</sub>, std<sub>1</sub>, ext<sub>5</sub>, std<sub>2</sub>, etc. If <4 exts are available, distribute ext injections among those available so that sequence thru std<sub>4</sub> is run.) Det. peak hts and calc. ratios of propylene glycol, glycerol, and triethylene glycol to butylene glycol for each std and sample soln. Plot peak ht ratios against polyol concn for std solns and construct std curve for each humectant. Det. concn in mg/100 mL for propylene glycol, glycerol, and triethylene glycol in sample soln from resp. std curves.

% Humectant = (mg/100 mL) × 0.01.

**Total Alkaloids (As Nicotine)****Distillation Method (45)—Official Final Action**

## 3.151

**Apparatus**

(a) *Distillation apparatus*.—500 mL Kjeldahl flask fitted with inlet tube for steam, trap bulb, and condenser; Griffith still (Tobacco Sci. 1, 130(1957), available from Lab Glass, Inc., PO Box 5067, Kingsport, TN 37663); or other suitable steam distn app.

(b) *Spectrophotometer*.—Beckman Instruments Model DU (replaced by Models 24/25) or other instrument capable of accurately measuring *A* in 200–300 nm range, equipped with 1 cm quartz cells.

## 3.152

**Reagents**

(a) *Alkali-salt soln*.—Dissolve 300 g NaOH in 700 mL H<sub>2</sub>O and sat. with NaCl.

(b) *Silicotungstic acid soln (for gravimetric determination)*.—Dissolve 120 g SiO<sub>2</sub>·12WO<sub>3</sub>·26H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L. (Soln should be clear and free from green color.)

## 3.153

**Standardization**

(Caution: Nicotine is very toxic. Avoid contact with skin and eyes. See 51.011 and 51.015.)

Purify best grade of nicotine com. available by successive vac. distns until center cuts from 2 successive distns have same *a* at 259 nm (ca 34.3). Accurately weigh ca 0.2 g purified nicotine; dissolve in and dil. to 1 L with ca 0.05*N* HCl. Dil. 10 mL aliquot of this soln to 100 mL with ca 0.05*N* HCl. Det. *A* at 259 nm and calc. *a* = *A*/(*c* × *b*), where *c* is concn of nicotine in g/L and *b* is cell length in cm.

## 3.154

**Distillation**

Accurately weigh 2–5 g tobacco sample and transfer to distn flask or app. (If final detn of nicotine is gravimetric, use sample

contg  $\geq 0.1$  g alkaloids; if spectrophtric, use  $\geq 2$  g sample.) (If Griffith still is used, use 0.05–0.2 g sample.) Place 25 mL HCl (1+4) in receiver (1 L vol. flask is desirable) and place receiver so that condenser tube dips into acid. (With Griffith still, use 10 mL HCl (1+4) in 250 mL vol. flask.) Add 50 mL alkali-salt soln to distn flask so that sample is rinsed into bottom of flask. (With Griffith still, use 5 mL alkali-salt soln.) If large vol. of liq. is required for proper function of still, add more alkali-salt soln; do not dil. Connect flask to app. immediately and steam distil with as rapid current of steam as can be condensed efficiently. Effluent condensate should not be above room temp. Apply heat to distn flask from burner, mantle, or other heat source to keep vol. in flask approx. const. Collect ca 900 mL condensate (or distil addnl 100 mL after condensate shows no nicotine by silicotungstic acid test). (With Griffith still, collect 225 mL.) Dil. distillate to vol.

**3.155****Determination**

(a) *Spectrophotometric*.—Dil. aliquots of distillate (if necessary) with 0.05N HCl so that  $A$  at 259 nm is 0.5–0.8 and read  $A$  at 236, 259, and 282 nm. Calc. corrected  $A'_{259} = 1.059 \times [\text{observed } A_{259} - \frac{1}{2}(A_{236} + A_{282})]$  after correcting all observed  $A$  values to original distillate vol. basis. Conc'n,  $c$ , of alkaloids as nicotine in g/L is given by  $c = A'_{259}/(a \times b)$ , where  $a$  is absorptivity at 259 nm, and  $b$  is cell length in cm.

% alkaloid (as nicotine) =  $c \times \text{vol. distillate (L)} \times 100/\text{g sample}$ .

(b) *Gravimetric*.—Det. alkaloids in distillate as in 6.176, but double amt of silicotungstic acid specified, i.e., 2 mL/each 10 mg alkaloids expected.

**Cundiff-Markunas Method (45)—Official Final Action**

(Total alkaloids (as nicotine), tertiary alkaloids (as nicotine), and secondary alkaloids (as nornicotine))

**3.156****Reagents**

(a) *Benzene-chloroform soln.*—Mix equal parts by vol. of benzene and  $\text{CHCl}_3$  and sat. with  $\text{H}_2\text{O}$ .

(b) *Sodium hydroxide soln.*—36%. Dissolve 500 g NaOH in  $\text{H}_2\text{O}$  and dil. to 1 L.

(c) *Dilute acetic acid.*—5%. Dil. 50 mL HOAc to 1 L with  $\text{H}_2\text{O}$ .

(d) *Crystal violet indicator.*—Dissolve 0.5 g crystal violet in 100 mL HOAc.

(e) *Perchloric acid std soln.*—0.025N. Add 4.7 mL 72%  $\text{HClO}_4$  to freshly opened 5 lb bottle HOAc and mix. (Caution: See 51.022 and 51.028(a) and (d).) Stdze as follows: Accurately weigh 0.1 g KH phthalate (NBS) into 125 mL erlenmeyer, add 50 mL HOAc, and heat to dissolve. Cool, add 2 drops indicator, and titr. to blue-green end point. Perform blank titrn on 50 mL HOAc and 2 drops indicator soln, and correct vol. of titrant.

$N = \text{wt KH phthalate} \times 4.896/\text{mL } \text{HClO}_4 \text{ soln.}$

**3.157****Determination**

Accurately weigh 2.5 g finely ground tobacco into 250 mL erlenmeyer. Add 15 mL 5% HOAc and swirl until tobacco is thoroly wetted. Pipet 100 mL benzene- $\text{CHCl}_3$  soln into flask, and then 10 mL 36% NaOH soln. Stopper flask tightly and shake 20 min, using wrist-action shaker. Add 4.5–5 g (2 teaspoonfuls) Filter-Cel, mix, and filter most of benzene layer thru Whatman No. 2 paper into second flask. If filtrate has any turbidity, add 2–2.5 g (1 teaspoonful) addnl Filter-Cel and refilter thru Whatman No. 2 paper. Filtrate must be clear.

Pipet 25 mL aliquots of filtrate into each of two 125 mL erlenmeyers. Pass stream of air over surface of soln in first flask

5 min, add 2 drops indicator, and titr. to green end point with 0.025N  $\text{HClO}_4$ . Add 1.0 mL  $\text{Ac}_2\text{O}$  to second flask and let stand  $\geq 15$  min. Add 25 mL HOAc and 2 drops indicator, and titr. to blue-green end point with 0.025N  $\text{HClO}_4$ . Take first appearance of blue-green thruout soln as end point. For each series of analyses perform blank titrns and correct respective vols of titrant.

Calc. % alkaloids as follows: % total alkaloids (as nicotine) =  $V_1 \times N \times 32.45/\text{wt sample}$ ; % tertiary alkaloids (as nicotine) =  $(2V_2 - V_1) \times N \times 32.45/\text{wt sample}$ ; % secondary alkaloids (as nornicotine) =  $2(V_1 - V_2) \times N \times 29.64/\text{wt sample}$ ; where  $V_1$  = vol. titrant for nonacetylated aliquot;  $V_2$  = vol. titrant for acetylated aliquot; and  $N$  = normality  $\text{HClO}_4$ .

**Nicotine on Cambridge Filter Pads****Gas-Liquid Chromatographic Method (46)****Official First Action****3.158****Apparatus and Reagents**

(a) *Gas chromatograph*.—With flame ionization detector, heated injection port, and thermostated column oven. Following conditions have been found satisfactory: Column, 1.8 m (6')  $\times$   $\frac{1}{8}$ " stainless steel; packing, 2% KOH and 10% Carbowax 20M (based on final packing wt) on 45–60 mesh calcined diat. earth (such as Chromosorb W, or equiv.), resieved before use to mesh range to remove fines and lumps; temps ( $^\circ$ ): column 165, detector and injection port 200–250; carrier gas flow, ca 40 mL/min. Adjust H and air flows for max. sensitivity and stability. Under these conditions, column should have ht equiv. to theoretical plate (HETP)  $< 1$  mm and resolution of  $> 2$ , calcd with nicotine and anethole.

(b) *Measuring system*.—Measure peak areas with electronic integrator or other system with resolution of  $\geq 1$  count/mv-sec.

(c) *Mechanical shaker*.—Capable of extg  $\geq 99\%$  nicotine. Burrell Wrist-Action shaker has been found satisfactory.

(d) *Extracting soln.*—2-Propanol contg 1 mg anethole/mL as internal std for nicotine. If  $\text{H}_2\text{O}$  is also to be detd, add 20 mg  $\text{EtOH}$ /mL 2-propanol as addnl internal std.

(e) *Nicotine std solns.*—(1) *Stock soln.*—Weigh 2.500 g nicotine, 3.153, or equiv. amt of nicotine salt. Transfer quant. into 100 mL vol. flask, and dil. to vol. with extg soln. (2) *Working std solns.*—Pipet 1, 2, 3, 4, and 5 mL stock soln into five 100 mL vol. flasks, and dil. to vol. with extg soln (0.25, 0.50, 0.75, 1.00, and 1.25 mg nicotine/mL). (Caution: See precaution in 3.153.)

**3.159****Extraction**

Place Cambridge filter material in flask or serum bottle accommodated by shaker used, add 10.00 mL extg soln, stopper, and shake until  $\geq 99\%$  of nicotine is extd (usually ca 15 min).

**3.160****Standardization**

Prime column with aliquots of 1.25 mg/mL std soln. Let baseline stabilize, inject 1  $\mu\text{L}$  each std soln in succession, and repeat sequence 3 times. Det. area ratio (nicotine:anethole) for each injection, and calc. slope and intercept of response curve, preferably by method of least squares (See *Definition of Terms and Explanatory Notes No. (24)*). Correlation coefficient should be  $\geq 0.99$  and intercept  $\leq 0.05$  mg/mL.

**3.161****Determination**

Prime column with aliquots of ext, 3.159. Let baseline stabilize, and inject 1  $\mu\text{L}$  of each sample soln. Calc. nicotine concn in soln ( $C$ , mg/mL) =  $mx + b$ , where  $m$  = slope of stdzn curve,  $b$  = intercept, and  $x$  = area ratio of nicotine to anethole.

Nicotine yield/cigaret =  $(C \times 10.00)/(\text{No. cigarets}/\text{pad})$

**Menthol (47)—Official Final Action****Colorimetric Method****3.162****Apparatus and Reagents**

- (a) *Distillation apparatus*.—See Fig. 3:07.  
 (b) *Spectrophotometer*.—With matched cells; capable of measuring  $A$  at 550 nm.  
 (c) *Menthol std soln.*—1 mg/mL. Accurately weigh 100 mg USP *l*-menthol into 100 mL vol. flask, add alcohol to dissolve, and dil. to vol. with alcohol.  
 (d) *DMAB color reagent*.—Dissolve 0.5 g *p*-dimethylamino-benzaldehyde (Eastman Kodak, white label) in 100 mL  $H_2SO_4$  (1.6+1).

**3.163****Preparation of Calibration Curve**

Prep. dil. stds by pipeting aliquots contg 0, 3, 4, 6, 8, and 10 mg menthol into 100 mL vol. flasks and dilg to vol. with alcohol (1+1). Pipet 1 mL each dil. std into 10 mL test tube, add 5 mL color reagent, mix, and place in boiling  $H_2O$  bath *exactly* 2 min. Cool in tap  $H_2O$ , and within 15 min det.  $A$  at 550 nm against 0 std. Prep. calibration curve by plotting  $A$  against menthol concn (mg/100 mL).

**3.164****Determination**

Accurately weigh 2.00–2.15 g cigaret filler and transfer to distn flask, **A**. Add 80 mL  $H_2O$  and few boiling stones, connect flask to condenser with tube, **B**, attach adapter, **C**, to condenser, and immerse tip in 20 mL alcohol in 100 mL vol. receiving flask.

Gently heat distn flask until distn begins; then increase heat and lower receiving flask, **D**, so tip of adapter is no longer immersed. Distil until 20 mL distillate collects. Disconnect condenser from tube, and wash down condenser with alcohol. Remove receiving flask, dil. distillate to ca 70 mL with alcohol, and add  $H_2O$  almost to vol. Mix, add alcohol to vol., and mix again.

Pipet 1 mL distillate into 10 mL test tube, add 5 mL color reagent, mix, and place in boiling  $H_2O$  bath *exactly* 2 min. Cool in tap  $H_2O$ , and within 15 min det.  $A$  at 550 nm, using "color" soln from nonmentholated tobacco carried thru detn as blank. (If nonmentholated sample corresponding to mentholated sample is not available, use reagent blank.) Use nonmentholated

tobacco blank within 15 min after color development step. Fresh nonmentholated tobacco blank soln may be required during multiple sample runs. Det. mg menthol from calibration curve.  
 $\% \text{ Menthol} = \text{mg menthol}/(\text{g original sample} \times 10)$ .

**Gas Chromatographic Method****3.165****Apparatus and Reagents**

(a) *Gas chromatograph*.—Equipped with flame ionization detector and thermostated injection port and column oven. Use following conditions for analysis: Column, 1.5 m (5')  $\times$   $\frac{1}{8}$ " od stainless steel packed with 10% (w/w) silicone oil DC-550 on 60–80 mesh Chromosorb W; temps ( $^{\circ}$ ): column 150, detector 150, injection port 175; N carrier gas flow ca 35 mL/min. Adjust H and air flows for max. sensitivity and reasonable stability.

(b) *Mechanical shaker*.—Wrist action.

(c) *Menthol-anethole std soln.*—0.250 mg menthol and 0.50 mg anethole/mL. Weigh exactly 0.5000 g tech. grade anethole and wash into 1 L vol. flask with 200 mL alcohol. Transfer 0.2500 g USP *l*-menthol to the vol. flask with enough alcohol to bring to vol. Store soln in dark g-s bottle. Do not use >6 weeks.

(d) *Extracting soln.*—0.50 mg anethole/mL. Dissolve 1.000 g anethole in alcohol in 2 L vol. flask, dil. to vol. with alcohol, and store in dark.

**3.166****Determination of Ratio Factor**

Weigh ca 3 g nonmentholated control filler, contg all usual humectants but no menthol or anethole, into 125 mL rubber-stoppered flask. Pipet 50 mL std menthol-anethole soln into flask, stopper, and shake 1 hr on mech. shaker. Let solids settle 15 min and chromatograph 2  $\mu$ L aliquot of supernate. Repeat twice more to obtain total of 3 replicates of std chromatogram. For quant. results, inject both std and unknown samples by inserting 2" (5 cm) needle to hilt, injecting 2  $\mu$ L rapidly, and withdrawing needle at once. (Menthol elutes in ca 3 min, anethole in ca 5 min.) After ca 10 min, all other compds are eluted and new injection can be made.

Draw baselines under menthol and anethole peaks and measure peak hts in mm. Using mean peak ht of menthol and anethole from 3 std chromatograms, calc. std ratio factor of menthol to anethole as follows:

Std ratio factor = peak ht for menthol (0.25 mg/mL)/peak ht for anethole (0.50 mg/mL).

**3.167****Determination**

Accurately weigh 8–8.5 g mentholated cigarette filler and place in 250 mL rubber-stoppered erlenmeyer. Pipet 100 mL extg soln into flask, stopper, and mech. shake 2 hr. Let solids settle 15 min and chromatograph 2  $\mu$ L aliquot of supernate. Draw baselines under menthol and anethole peaks and measure peak hts in mm. Calc. ratio factor of unknown menthol as follows:

Ratio factor for unknown = peak ht for unknown menthol/peak ht for anethole (0.50 mg/mL).

$\% \text{ Menthol} = (\text{unknown ratio factor} \times 0.25 \times 10)/(\text{std ratio factor} \times \text{g sample})$ .

## 4. Disinfectants

### Phenol Coefficient (1)—Official Final Action

(Applicable to testing disinfectants miscible with H<sub>2</sub>O that do not exert bacteriostatic effects that cannot be neutrd by one of subculture media specified, or overcome by suitable subtransfer procedures. The 95% confidence limits are  $\pm 12\%$ .)

#### 1. Using *Salmonella typhi*

##### 4.001

##### Culture Media

(a) *Nutrient broth*.—Boil 5 g beef ext (Difco), 5 g NaCl, and 10 g peptone (Anatone, peptic hydrolysate of pork tissues, manufactured by American Laboratories, Inc., 4410 S 102nd St, Omaha, NB 68127) in 1 L H<sub>2</sub>O 20 min, and dil. to vol. with H<sub>2</sub>O; adjust to pH 6.8. (If colorimetric method is used, adjust broth to give dark green with bromothymol blue.) Filter thru paper, place 10 mL portions in 20 × 150 mm test tubes, and autoclave 20 min at 121°. Use this broth for daily transfers of test cultures.

(b) *Synthetic broth*.—*Soln A*: Dissolve 0.05 g L-cystine, 0.37 g DL-methionine, 0.4 g L-arginine.HCl, 0.3 g DL-histidine.HCl, 0.85 g L-lysine.HCl, 0.21 g L-tyrosine, 0.5 g DL-threonine, 1.0 g DL-valine, 0.8 g L-leucine, 0.44 g DL-isoleucine, 0.06 g glycine, 0.61 g DL-serine, 0.43 g DL-alanine, 1.3 g L-glutamic acid.HCl, 0.45 g L-aspartic acid, 0.26 g DL-phenylalanine, 0.05 g DL-tryptophan, and 0.05 g L-proline in 500 mL H<sub>2</sub>O contg 18 mL 1N NaOH.

*Soln B*: Dissolve 3.0 g NaCl, 0.2 g KCl, 0.1 g MgSO<sub>4</sub>·7H<sub>2</sub>O, 1.5 g KH<sub>2</sub>PO<sub>4</sub>, 4.0 g Na<sub>2</sub>HPO<sub>4</sub>, 0.01 g thiamine.HCl, and 0.01 g niacinamide in 500 mL H<sub>2</sub>O.

Mix *Solns A* and *B*, dispense in 10 mL portions in 20 × 150 mm tubes, and autoclave 20 min at 121°. Before using for daily transfers of test cultures, aseptically add 0.1 mL sterile 10% glucose soln per tube. Grow cultures with tube slanted 8° from horizontal.

(c) *Nutrient agar*.—Dissolve 1.5% Bacto agar (Difco) in nutrient broth and adjust to pH 7.2–7.4 (blue-green with bromothymol blue) or in synthetic broth, tube, autoclave, and slant.

(d) *Subculture media*.—Use (1), (2), or (3), whichever gives lowest result. (Com. dehydrated brands made to conform with preceding specifications may be used.) With oxidizing products and products formulated with toxic compds contg certain heavy metals like Hg, (2) will usually give lowest result. With products contg cationic surface active materials, (3) will usually give lowest result. See also 4.009, par. 5.

(1) *Nutrient broth* described in (a);

(2) *Fluid thioglycolate medium USP XX*: Mix 0.5 g L-cystine, 0.75 g agar, 2.5 g NaCl, 5.5 g glucose.H<sub>2</sub>O, 5.0 g H<sub>2</sub>O-sol. yeast ext, and 15.0 g pancreatic digest of casein with 1 L H<sub>2</sub>O. Heat on H<sub>2</sub>O bath to dissolve, add 0.5 g Na thioglycolate or 0.3 g thioglycolic acid, and adjust with 1N NaOH to pH 7.1 $\pm$ 0.2. If filtration is necessary, reheat without boiling and filter hot thru moistened filter paper. Add 1.0 mL freshly prepd 0.1% Na resazurin soln, transfer 10 mL portions to 20 × 150 mm tubes, and autoclave 20 min at 121°. Cool at once to 25° and store at 20–30°, protected from light.

(3) "*Lethen broth*": Dissolve 0.7 g lecithin (Azolectin, Associated Concentrates, 32–30 61st St, Woodside, NY 11377) and 5.0 g polysorbate 80 (Tween 80, or equiv.) in 400 mL hot H<sub>2</sub>O and boil until clear. Add 600 mL soln of 5.0 g beef ext (Difco), 10.0 g peptone (Anatone, (a)), and 5 g NaCl in H<sub>2</sub>O, and boil 10 min. Adjust with 1N NaOH and/or 1N HCl to pH 7.0  $\pm$ 0.2 and filter thru coarse paper; transfer 10 mL portions to 20 × 150 mm tubes, and autoclave 20 min at 121°.

(4) *Cystine trypticase agar (BBL)*: Suspend 29.5 g in 1 L H<sub>2</sub>O. Heat gently with frequent agitation and boil ca 1 min or until soln is complete. Transfer 10 mL portions to 20 × 150 mm tubes, and autoclave 15 min at 12 lb pressure. Cool in upright position and store  $\leq 25$  days at 20–30°. Use for monthly transfer of stab stock cultures of *Ps. aeruginosa* PRD 10 (ATCC 15442).

(5) *Other subculture media*: Use 4.001(d)(2) with 0.7 g lecithin (Azolectin, Associated Concentrates, Inc., 32–30 61st St, Woodside, NY 11377) and 5.0 g polysorbate 80 (Tween 80, or equiv.) added; or suspend 29.8 g prepd fluid thioglycolate medium (Difco), 0.7 g lecithin, and 5.0 g polysorbate 80 in 1 L H<sub>2</sub>O, and boil until soln is clear. Cool, dispense in 10 mL portions in 20 × 150 mm tubes, and autoclave 20 min at 121°. Store at 20–30°. Protect from light.

##### 4.002

##### Apparatus and Reagents

(a) *Glassware*.—1, 5, and 10 mL vol. pipets; 1, 5, and 10 mL Mohr pipets graduated to 0.1 mL or less; 100 mL g-s cylinders graduated in 1 mL divisions; Pyrex lipped test tubes, 25 × 150 mm (medication tubes); bacteriological culture tubes, 20 × 150 mm (test culture and subculture tubes). Plug medication tubes with cotton wrapped in 1 layer of cheese cloth. Sterilize all glassware 2 hr in hot air oven at 180°. Loosely plug pipets with cotton at mouth and place in closed metal containers before sterilizing.

(b) *Water bath*.—Insulated, relatively deep H<sub>2</sub>O bath, with cover having  $\geq 10$  well-spaced holes which admit medication tubes but not their lips.

(c) *Racks*.—Any convenient style. Blocks of wood (size depending on space in incubator) with deep holes are satisfactory. Have holes well spaced to ensure quick manipulation of tubes. It is convenient to have them large enough to admit medication tubes while dilns are being made.

(d) *Transfer loop*.—Make 4 mm id single loop at end of 50–75 mm (2–3") Pt or Pt alloy wire No. 23 B&S gage or 4 mm loop fused on 75 mm (3") shaft (available from Matthey-Bishop, Inc., Malvern, PA 19355). Fit other end in suitable holder (glass or Al rod). Bend loop at 30° angle with stem, Fig. 4:01.

(e) *Test organism*.—Hopkins strain 26 of *Salmonella typhi* (Schroeter) Warren and Scott, ATCC No. 6539 (formerly called *Bac. typhosus* and *Eberthella typhosa*). Maintain stock culture on nutrient agar slants by monthly transfers. Incubate new stock transfer 2 days at 37°; then store at 2–5°. From stock culture inoculate tube of nutrient broth and make at least 4 consecutive daily transfers ( $\leq 30$ ) in nutrient broth, incubating at 37°, before using culture for testing. (If only 1 daily transfer has been missed, it is not necessary to repeat the 4 consecutive transfers.) Use 22–26 hr culture of organism grown in nutrient broth at 37° in test. Shake, and let settle 15 min before using.

With *Ps. aeruginosa* PRD 10, proceed as in 4.011.

(f) *Phenol stock soln*.—5% (w/v). Weigh 50 g USP phenol, which congeals at  $\geq 40^\circ$ , in beaker. Dissolve in H<sub>2</sub>O, rinse soln into 1 L vol. flask, and dil. to vol. Stdze with 0.1N KBr-KBrO<sub>3</sub> soln, (g), as follows: Transfer 25 mL stock soln to 500 mL vol. flask and dil. to vol. with H<sub>2</sub>O. Transfer 15 mL aliquot of dild soln to 500 mL I flask and add 30 mL std KBr-KBrO<sub>3</sub> soln. Add 5 mL HCl and immediately insert stopper. Shake frequently during 30 min and let stand 15 min. Remove stopper just enough to quickly add 5 mL 20% KI soln, taking care that no Br vapors escape, and immediately stopper flask. Shake thoroly, remove

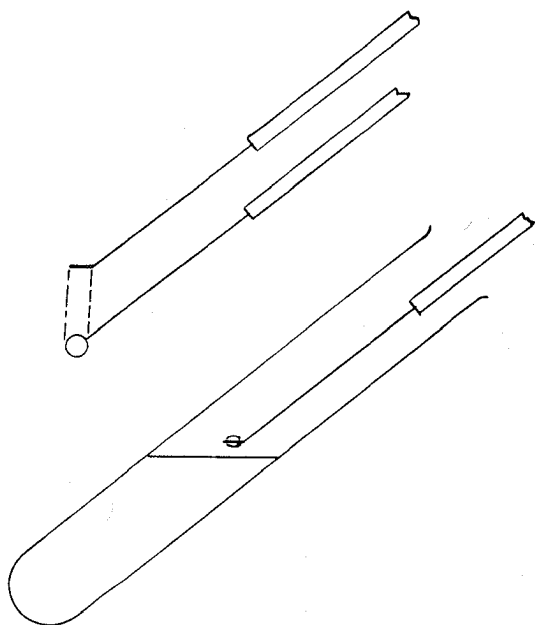

FIG. 4:01—Transfer loop and manner of using in phenol coefficient technic

stopper, and rinse it and neck of flask with little  $H_2O$  so that washings flow into flask. Titr. with 0.1*N*  $Na_2S_2O_3$ , using starch indicator, 6.005(f). 1 mL 0.1*N*  $KBr-KBrO_3$  = 0.001569 g phenol.

$$\% \text{ phenol in stock soln} = (30 - \text{mL } 0.1\text{N } Na_2S_2O_3 \text{ soln from titrn}) \times 0.001569 \times 1333 \times 100/1000;$$

where 30 = mL 0.1*N*  $KBr-KBrO_3$  soln added, 0.001569 = g phenol equiv. to 1 mL 0.1*N*  $KBr-KBrO_3$  soln, 1333 = diln factor, and 1000 = original vol. phenol stock soln.

If necessary, adjust stock soln to  $5.00 \pm 0.05\%$  phenol by adding  $H_2O$  or phenol. Keep in well stoppered amber bottles in cool place, protected from light.

(g) *Potassium bromide-bromate soln.*—0.1*N*. Prep. as in 50.020. Stdze as follows: Transfer 30 mL to I flask, and add 25 mL  $H_2O$ , 5 mL 20% KI soln, and 5 mL HCl. Shake thoroly and titr. with 0.1*N*  $Na_2S_2O_3$ , using starch indicator, 6.005(f).

#### 4.003

#### Operating Technic

Make 1% stock diln of substance to be tested (or any other convenient diln, depending on anticipated concn) in g-s cylinder. Make final dilns, from 1% stock diln, directly into medication tubes and remove all excess >5 mL. (Range of dilns should cover killing limits of disinfectant in 5–15 min and should at same time be close enough for accuracy.) From 5% stock phenol soln (1–20) dil. further to make 1–90 and 1–100 dilns, and place in medication tubes. Place these tubes, contg 5 mL each of final dilns of disinfectant and of phenol, and tube contg test culture in  $H_2O$  bath at  $20^\circ$  and leave 5 min. Add 0.5 mL test culture to each of dilns at time intervals corresponding to intervals at which transfers are to be made. (Thus, by time 10 tubes have been seeded at 30 sec intervals, 4.5 min has elapsed, and 30 sec interval intervenes before transference to subculture begins.) Add culture from graduated pipet large enough to seed all tubes in any one set. In using *Ps. aeruginosa* PRD 10 (ATCC 15442), proceed as in 4.011.

In inoculating medication tubes, hold them in slanting position after removal from bath, insert pipet to just above surface of disinfectant, and run in culture without letting tip touch disin-

fectant. After adding culture, agitate tubes gently but thoroly to insure even distribution of bacteria, and replace in bath; 5 min after seeding first medication tube, transfer 1 loopful of mixt. of culture and did disinfectant from medication tube to corresponding subculture tube. To facilitate transfer of uniform drops of medication mixt., hold tube at  $60^\circ$  angle, and withdraw loop so that plane of loop is parallel with surface of liq. (Fig. 4:01). After 30 sec, transfer loopful from second medication tube to second subculture tube and continue process for each successive diln; 5 min after making first transfer, begin second set of transfers for 10 min period, and finally repeat for 15 min period.

Gently agitate medication tubes before taking each interval loop subsample for transfer to subculture medium. Before each transfer, heat loop to redness in flame and flame mouth of every tube. Sterilize loop immediately after each transfer (before replugging tubes) to allow time for cooling. Use care in transferring and seeding to prevent pipet or needle from touching sides or mouth of medication tube, and see that no cotton threads adhere to inner sides or mouths of tubes. Incubate subculture 48 hr at  $37^\circ$  and read results. Thoroly agitate individual subculture tubes before incubation. Macroscopic examination is usually sufficient. Occasionally 3-day incubation period, agar streak, microscopic examination, or agglutination with antityphoid serum may be necessary to det. feeble growth or suspected contamination.

#### 4.004

#### Calculation

Express results in terms of phenol coefficient number, or highest diln killing test organism in 10 min but not in 5 min, whichever most accurately reflects germicidal value of disinfectant. Phenol coefficient is number obtained by dividing numerical value of greatest diln (denominator of fraction expressing diln) of disinfectant capable of killing *S. typhi* in 10 min but not in 5 min by greatest diln of phenol showing same results.

#### Example:

Diln	Disinfectant (X):		
	5 Min	10 Min	15 Min
1–300	0	0	0
1–325	+	0	0
1–350	+	0	0
1–375	+	+	0
1–400	+	+	+
Phenol:			
1–90	+	0	0
1–100	+	+	+

Phenol coefficient would be  $\frac{350}{90} = 3.89$ .

Test is satisfactory only when phenol control gives one of following readings:

Phenol	5 Min	10 Min	15 Min
1–90	+ or 0	+ or 0	0
1–100	+	+	+ or 0

If none of dilns of disinfectant shows growth in 5 min and killing in 10 min, est. hypothetical diln only when any 3 consecutive dilns show following results: first, no growth in 5 min; second, growth in 5 and 10 min but not in 15 min; and third, growth in 5, 10, and 15 min.

#### Example:

Diln	Disinfectant (X):		
	5 Min	10 Min	15 Min
1–300	0	0	0
1–350	+	+	0
1–400	+	+	+
Phenol:			
1–90	0	0	0
1–100	+	+	0

Phenol coefficient would be  $\frac{325}{95} = 3.42$ .

To avoid giving impression of fictitious accuracy, calc. phenol coefficient to nearest 0.1. Thus, in examples cited above, phenol coefficients would be reported as 3.9 and 3.4, instead of 3.89 and 3.42.

*Note:* Although it is commonly accepted criterion that disinfectants be at diln equiv. in germicidal efficiency to phenol against *S. typhi* by calcg  $20 \times S. typhi$  coefficient to det. number of parts  $H_2O$  in which 1 part disinfectant may be mixed, this should be regarded as presumptive and is subject to confirmation by Use-Diln Method.

#### 4.005 2. Using *Staphylococcus aureus* (1)

Proceed as in 4.001–4.004, except change phenol dilns and test organisms. Use 22–26 hr culture of *Staph. aureus* FDA 209, ATCC No. 6538, having at  $20^\circ$  at least resistance indicated by following:

Phenol	5 Min	10 Min	15 Min
1–60	+ or 0	+ or 0	0
1–70	+	+	+

*Note:* Calc. results as in 4.004. If conversion  $20 \times Staph. aureus$  coefficient is used to det. number of parts  $H_2O$  in which 1 part germicide may be incorporated to disinfect where pyogenic organisms are objective, this diln is subject to confirmation by Use-Diln Method.

#### 4.006 3. Using *Pseudomonas aeruginosa* Official First Action

Proceed as in 4.001–4.004. Use 22–26 hr culture of *Ps. aeruginosa* PRD 10 (ATCC 15442), having resistance to phenol at  $20^\circ$  at least as follows:

Phenol	5 Min	10 Min	15 Min
1–80	+ or 0	+ or 0	0
1–90	+	+	+

#### Use-Dilution Method (2)—Official Final Action

(Applicable to testing disinfectants miscible with  $H_2O$  to confirm phenol coefficient results and to det. max. dilns effective for practical disinfection)

##### 1. Using *Salmonella choleraesuis*

#### 4.007

#### Reagents

- Culture media.*—See 4.001.
- Test organism, Salmonella choleraesuis.*—(ATCC 10708). Maintain stock culture on nutrient agar slants by monthly transfers. Incubate new stock transfer 2 days at  $37^\circ$ ; then store at  $2-5^\circ$ . From stock culture inoculate tube of nutrient broth and incubate at  $37^\circ$ . Make 3 consecutive 24 hr transfers; then inoculate tubes of nutrient broth (2 for each 10 carriers to be tested), using one loop of inoculum with each tube; incubate 48–54 hr at  $37^\circ$ .
- Phenol.*—See 4.002(f).
- Sterile distilled water.*—Prep. stock supply of  $H_2O$  in 1 L flasks, plug with cotton, sterilize 20 min at  $121^\circ$ , and use to prep. dilns of medicants.
- Asparagine soln.*—Make stock supply of 0.1% asparagine ("Bacto") soln in  $H_2O$  in erlenmeyer of convenient size, plug with cotton, and sterilize 20 min at  $121^\circ$ . Use to cover metal carriers for sterilization and storage.
- Sodium hydroxide soln.*—Approx. 1N (4%). (For cleaning metal carriers before use.)

#### 4.008

#### Apparatus

- Glassware.*—As in 4.002(a). Also: straight side Pyrex test tubes,  $20 \times 150$  mm;  $15 \times 110$  mm petri dishes; 100 mL, 300

mL, and 1 L erlenmeyers. Sterilize petri dishes in closed metal containers.

- Water bath and racks.*—See 4.002(b) and (c).

- Transfer loops and needles.*—(1) See 4.002(d). (2) Make 3 mm right angle bend at end of 50–75 mm nichrome wire No. 18 B&S gage. Have other end in suitable holder (glass or Al rod).

- Carriers.*—Polished stainless steel cylinders (penicillin cups),  $8 \pm 1$  mm od,  $6 \pm 1$  mm id, length  $10 \pm 1$  mm, of type 304 stainless steel, SS 18–8. (Obtainable from S. & L. Metal Products Corp., 58–29 57 Drive, Maspeth, NY 11378.)

- Petri dishes.*—Have available ca 6 sterile petri dishes matted with 2 layers of S&S No. 597 or Whatman No. 2, 9 cm filter paper.

#### 4.009

#### Operating Technic

Soak ring carriers overnight in 1N NaOH, rinse with tap  $H_2O$  until rinse  $H_2O$  is neut. to phthln, then rinse twice with distd  $H_2O$ ; place cleaned ring carriers in multiples of 10 in cotton-plugged erlenmeyers or  $25 \times 150$  mm cotton plugged Pyrex test tubes, cover with asparagine soln, 4.007(e), sterilize 20 min at  $121^\circ$ , cool, and hold at room temp. Transfer 20 sterile ring carriers, using flamed nichrome wire hook, into 20 mL 48–54 hr nutrient broth test culture in sterile  $25 \times 150$  mm medication tube. After 15 min contact period remove cylinders, using flamed nichrome wire hook, and place on end in vertical position in sterile petri dish matted with filter paper, 4.008(e). Cover and place in incubator at  $37^\circ$  and let dry  $\geq 20$  min but  $\leq 60$  min. Hold broth culture for detn of its resistance to phenol by phenol coefficient method, 4.003.

From 5% stock phenol soln (1–20) make 1–90 and 1–100 dilns directly into medication tubes. Place tube for each diln in  $H_2O$  bath and let come to  $20^\circ$ . Make stock soln of germicide to be tested in sterile g-s cylinder. From this soln make 10 mL dilns to be tested, depending upon phenol coefficient found and/or claimed against *S. typhi* at  $20^\circ$ , directly into each of ten  $25 \times 150$  mm medication tubes; place the 10 tubes in  $H_2O$  bath at  $20^\circ$  and let come to temp. Det. diln to be tested by multiplying phenol coefficient number found and/or claimed by 20 to det. number of parts  $H_2O$  in which 1 part germicide is to be incorporated. This detn is not required when disinfectant under test yields phenol coefficient that cannot be converted validly to presumptive use-diln, or when analyst det. that use-diln range can be found without resort to phenol coefficient test.

Add 0.5 mL of test culture suspension to 1–90 diln of phenol control; after 30 sec interval, add 0.5 mL to 1–100 diln of control, using sterile cotton-plugged pipets. After adding culture, agitate tubes gently but thoroly to distribute bacteria evenly, and replace in bath; 5 min after seeding first medication tube, transfer 1 loopful of mixt. of culture and dild phenol from medication tube to corresponding subculture tube. After 30 sec, transfer loopful from second medication tube; 5 min after making first set of transfers begin second set of transfers for 10 min period; and finally repeat for 15 min period. Use technic of loop sampling, flaming loop and mouths of tubes, and agitating medication and subculture tubes as in phenol coefficient method, 4.003. Incubate subcultures 48 hr at  $37^\circ$  and read results. Resistance in 48–54 hr culture of *S. choleraesuis* should fall within range specified for 24 hr culture of *S. typhi* in phenol coefficient method.

Add 1 contaminated dried cylinder carrier at 1 min intervals to each of the 10 tubes of use-diln of germicide to be tested. Thus, by time 10 tubes have been seeded, 9 min will have elapsed, plus 1 min interval before transfer of first carrier in series to individual tube of subculture broth. This interval is const for each tube with prescribed exposure period of 10 min.

The 1 min interval between transfers allows adequate time for flaming and cooling nichrome wire hook and making transfer in manner so as to drain all excess medication from carrier. Flame lips of medication and subculture tubes in conventional manner. Immediately after placing carrier in medication tube, swirl tube 3 times before placing it back in bath. Thoroughly shake subculture tubes, incubate 48 hr at 37°, and report results as + (growth) or - (no growth) values.

Where there is reason to suspect that lack of growth at conclusion of incubation period may be due to bacteriostatic action of medicant adsorbed on carrier that has not been neutralized by subculture medium used, transfer each ring to new tube of sterile medium and reincubate for additional 48 hr at 37°. Where solution under test is such that material adsorbed on ring carriers and transferred into subculture medium makes it unsuitable for growth of test organism, as may be case with concentrated acids and alkalis, products carrying antibiotics, and wax emulsions, transfer each ring to new tube of sterile medium 30 min after initial transfer and incubate both primary and secondary subculture tubes 48 hr at 37°. Results showing no growth on all 10 carriers will confirm phenol coefficient number found. Results showing growth on any of the 10 carriers indicate phenol coefficient number to be unsafe guide to dilution for use. In latter case, repeat test, using lower dilutions (higher concentrations) of germicide under study. Maximum dilution of germicide which kills test organism on 10 carriers in 10 min interval represents presumed maximum safe use-dilution for practical disinfection.

#### 4.010 2. Using *Staphylococcus aureus*

Proceed as in 4.009 except change phenol dilutions and test organism to those specified in 4.005. Use 48–54 hr culture of *Staph. aureus* FDA 209, ATCC No. 6538, having at least resistance specified for 24 hr culture at 20° in phenol coefficient method, 4.005. Results showing growth on any of 10 carriers indicate that dilution is too high for use in disinfecting where pyogenic bacteria must be killed. In such cases repeat test, using lower dilutions (higher concentrations). Maximum dilution of germicide which kills both this test organism and *S. choleraesuis* on 10 carriers in 10 min interval represents maximum presumed safe use-dilution for disinfecting in hospitals, clinics, and other places where pyogenic bacteria have special significance.

**Note:** While killing in 10 of 10 replicates specified provides reasonably reliable index in most cases, killing in 59 out of 60 replicates is necessary for confidence level of 95%.

#### 4.011 3. Using *Pseudomonas aeruginosa* Official First Action

Proceed as in 4.009. Use 48–54 hr nutrient broth culture *Ps. aeruginosa* PRD 10 (ATCC 15442). Carry stock culture on BBL CTA (cystine trypticase agar) in stab culture incubated 48 hr at 37° and stored at 5° with transfer every 30 days. Transfer nutrient broth test cultures daily for 30-day intervals with incubation at 37°. Make fresh transfer from stock culture every 30 days. Do

not shake 48–54 hr test culture but decant liquid culture aseptically, leaving pellicle behind, to obtain 20 mL culture for inoculating 20 carriers in medication tube.

#### Available Chlorine Germicidal Equivalent Concentration (3)—Official Final Action

(Applicable to H<sub>2</sub>O-miscible disinfectants for detergent available chlorine germicidal equivalent concentrations with products offered for use as sanitizing rinses for previously cleaned nonporous surfaces, especially where speed of action and capacity are essential considerations)

#### 4.012

#### Reagents

Use reagents specified in 4.001 and 4.002(e) and (f), and in addition:

(a) *Sterile distilled H<sub>2</sub>O*.—See 4.007(d).

(b) *Sterile phosphate buffer soln*.—pH 8.0. Add 97.5 mL solution containing 11.61 g anhydrous K<sub>2</sub>HPO<sub>4</sub> in 1 L H<sub>2</sub>O to 2.5 mL solution containing 9.08 g anhydrous KH<sub>2</sub>PO<sub>4</sub> in 1 L H<sub>2</sub>O and autoclave 20 min at 121° in cotton-plugged erlenmeyer.

(c) *NaOCl std stock soln*.—Approx. 5%. Store NaOCl stock solution in tightly closed bottle in refrigerator, and determine exact available chlorine concentration at frequent intervals by As<sub>2</sub>O<sub>3</sub> titration, 6.112.

(d) *Test organisms*.—Use *S. typhi* ATCC No. 6539 or *Staph. aureus* ATCC No. 6538 or both.

#### 4.013

#### Apparatus

See 4.002.

#### 4.014

#### Operating Technique

Determine resistance of test culture to phenol as in 4.001–4.005, and use cultures with resistance specified. Prepare, in sterile glass cylinders, NaOCl solutions containing 200, 100, and 50 ppm available chlorine in sterile buffer solution, 4.012(b). Transfer 10 mL of each solution to 25 × 150 mm medication tubes, place tubes in 20° H<sub>2</sub>O bath, and let come to temperature.

Starting with tube containing 200 ppm available chlorine, add 0.05 mL test culture prepared as in 4.002(e), shake, and return to H<sub>2</sub>O bath. After 1 min, make transfer to tube of appropriate subculture medium, 4.001(d), using flamed 4 mm loop. At 1.5 min, add another 0.05 mL culture to the 200 ppm chlorine solution, shake, and return to bath. After additional 1 min interval (2.5 min in test), make second subculture in same manner, and in 30 sec, or at 3 min time in test, add another 0.05 mL culture, shaking and returning to H<sub>2</sub>O bath. After another 1 min interval (4 min in test), make another transfer to tube of subculture medium.

Repeat operation to give total of 10 added increments. This requires total time of 14.5 min for each solution and addition of 0.5 mL total culture with subculture at standard 1 min intervals after addition of culture aliquots. At conclusion of test shake all subculture tubes and incubate 48 hr at 37°.

Repeat operation with solutions containing 100 and 50 ppm available chlorine. Prepare solution of germicide to be tested at concentration recommended

Table 4:01 Example for Determination of Chlorine Germicidal Equivalent Concentration

Germicide	Concn, ppm Avail. Cl	Subculture Series									
		1	2	3	4	5	6	7	8	9	10
NaOCl control	200	—	—	—	—	—	+	+	+	+	+
	100	—	—	—	+	+	+	+	+	+	+
	50	—	—	+	+	+	+	+	+	+	+
Unknown (X)	25	—	—	—	—	—	+	+	+	+	+
	20	—	—	—	—	+	+	+	+	+	+
	10	—	+	+	+	+	+	+	+	+	+

— = No growth      + = growth

or selected for study in sterile H<sub>2</sub>O in g-s graduate. Transfer 10 mL to 25 × 150 mm medication tubes, place in H<sub>2</sub>O bath, and let come to temp. Repeat operation with this soln.

To be considered equiv. in disinfecting activity to 200 ppm available Cl, unknown germicide must show absence of growth in as many consecutive tubes of subculture tube series as 200 ppm available Cl std. Det. activity equiv. to 100 and 50 ppm available Cl in same manner. See example, Table 4:01.

In this example, 25 ppm soln of germicide X could be considered equiv. to 200 ppm soln of available Cl, and 20 ppm soln equiv. to 100 ppm of available Cl, but 10 ppm soln of germicide X would not be considered equiv. in germicidal activity to 50 ppm of available Cl.

Draw conclusions relative to germicidal equiv. concns only when resistance of test culture to NaOCl control is such that ≥1 neg. increment is obtained at 50 ppm concn and 1 pos. increment is obtained at 200 ppm level.

#### Sporicidal Test (4)—Official Final Action

(Suitable for detg sporicidal activity of liq. and gaseous chems. Applicable to germicides for detg presence or absence of sporicidal activity against specified spore-forming bacteria in various situations and potential efficacy as sterilizing agent.)

#### 4.015

#### Reagents

(a) *Culture media*.—(1) *Soil extract nutrient broth*.—Ext 1 lb garden soil in 1 L H<sub>2</sub>O, filter several times thru S&S No. 588 paper, and dil. to vol. (pH should be ≥5.2). Add 5 g beef ext. (Difco), 5 g NaCl, and 10 g peptone (Anatone, 4.001(a)). Boil 20 min, dil. to vol., adjust with 1N NaOH to pH 6.9, and filter thru paper. Dispense in 10 mL portions into 25 × 150 mm tubes, and autoclave 20 min at 121°. Use this broth to propagate test culture of *Bacilli*.

(2) *Nutrient agar*.—See 4.001(c). Use slants of this medium to maintain stock culture of *Bacilli*.

(3) *Modified fluid thioglycolate medium USP XX*.—Prep. as in 4.001(d)(2), except add 20 mL 1N NaOH to each L before dispensing for sterilization. Use this medium to subculture spores exposed to 2.5N HCl. For spores exposed to unknown germicides, use fluid thioglycolate medium, 4.001(d)(2).

(4) *Soil extract-egg-meat medium*.—Add 1.5 g Bacto Egg-Meat Medium dehydrated (Difco) to 25 × 150 mm tube; then add 15 mL garden soil ext. (1), and sterilize 20 min at 121°. Use this medium to propagate test cultures of *Clostridia* and maintain stock cultures of species of this genus.

(b) *Test organisms*.—Use *Bacillus subtilis*, ATCC No. 19659, or *Clostridium sporogenes*, ATCC No. 3584, for routine evaluation. Method is also applicable for use with strains of *B. anthracis*, *Cl. tetani*, or other spore forming species.

(c) *Dilute hydrochloric acid*.—2.5N. Use to det. resistance of dried spores. Stdze and adjust to 2.5N as in 50.012.

#### 4.016

#### Apparatus

(a) *Glassware*.—Bacteriological culture tubes, unflared, 25 × 150 mm; 100 mL g-s cylinders graduated in 1 mL divisions; 65 mm id funnels; supply of 15 × 110 mm petri dishes matted with 2 sheets 9 cm S&S No. 597 or Whatman No. 2 filter paper. Sterilize all glassware and matted petri dishes 2 hr in air oven at 180°.

(b) *Water bath*.—See 4.002(b).

(c) *Racks*.—See 4.002(c).

(d) *Transfer loop, hook, and forceps*.—See 4.008(c).

(e) *Tissue grinder*.—Arthur H. Thomas Co., No. 3431-E20, Size B, or equiv.

(f) *Suture loop carrier*.—From spool of size 3 surgical silk

suture, prep. std loops by wrapping the silk around ordinary pencil 3 times, slipping coil so formed off end of pencil, and holding it firmly with thumb and index finger of left hand while passing another piece of suture through coil, knotting, and tying securely. Then shear off end of coil and knotted suture to within 2 mm. This should provide overall length of ca 65 mm of suture in 2-loop coil that can be conveniently handled in ordinary aseptic transfer procedure.

Ext loops in groups of 20 by immersion in 10 mL pet ether in stoppered, unflared test tube, shaking frequently during 30 min at room temp., and hold overnight (18–24 hr) at 2–5°. Shake, remove loops, drain, and dry.

(g) *Cylinder carriers*.—"Penicylinders," porcelain, 8 ± 1 mm od, 6 ± 1 mm id, 10 ± 1 mm long. (Available from Fisher Scientific Co., No. 7-907.) Sterilize 2 hr in 180° air oven. Wash used Penicylinders with Triton X-100 and rinse with H<sub>2</sub>O 4 times.

#### 4.017

#### Operating Technic

Grow all *Bacilli* in soil ext nutrient broth and all *Clostridia* in soil ext-meat-egg medium. Inoculate 3 tubes, using 1 loop stock culture, and incubate 72 hr at 37°. Place supply of suture loops and cylinder carriers in sep. petri dishes matted with filter paper, and sterilize 20 min at 121°. Use new loops for each test. Penicylinders must be free from chips or cracks. Filter *Cl. sporogenes* thru funnel contg 2 × 5 × 5 cm sq piece of moist cotton or glass wool into sterile 25 × 150 mm test tubes, using same funnel. In prepg *B. subtilis* culture, pour tube of 72 hr culture into tissue grinder and macerate to break up pellicle. Filter thru sterile funnel contg moist cotton or glass wool into sterile 25 × 150 mm tube, repeating operation for other 2 tubes. Place 10 sterile suture loops or Penicylinders into each of 3 tubes contg 10 mL filtrate from 72 hr culture of *Cl. sporogenes*, agitate, and let stand 10–15 min. Using this technic, contaminate 35 loops or cylinders. Place contaminated suture loops and/or cylinders into petri dish matted with 2 layers of filter paper. Drain. Proceed similarly for *B. subtilis*.

Place the 35 suture loops or cylinders contaminated with *Cl. sporogenes* or *B. subtilis* in vac. desiccator contg CaCl<sub>2</sub> and draw vac. of 69 cm (27") Hg for 20 min. Dry 24 hr under vac. (Spores dried and held under these conditions will retain resistance ≥7 days.)

Transfer 10 mL 2.5N HCl, 4.015(c), into sterile 25 × 150 mm tube. Place tube in 20° const temp. H<sub>2</sub>O bath and let come to temp. Rapidly transfer 4 dried, contaminated loop or cylinder carriers to acid tube. Transfer remaining dried, contaminated suture loop or cylinder carriers to tube of thioglycolate subculture medium, 4.015(a)(3), as viability control. After 2, 5, 10, and 20 min, withdraw individual loops or cylinders from acid and transfer to individual tubes of subculture medium. Rotate each tube vigorously 20 sec and resubtransfer. Incubate 21 days at 37°. Test spores should resist HCl ≥2 min, and many may resist HCl for full 20 min.

When testing sporicidal or sterilizing activity of gas, place carriers in polyethylene bags or in petri dishes with lids ajar. Certain gases may require rehydration of spores before exposure to gas. Rehydrate spores on carriers by 1 hr immersion in H<sub>2</sub>O, using ≤20 mL H<sub>2</sub>O/6 carriers. Drain carriers 20 min on petri dishes matted with filter paper. After exposure to gas, remove carriers, using aseptic technic to subculture media as specified in next par.

For aq. sporicides and sterilizers, place 10 mL product at diln recommended for use or under investigation into each of six 25 × 150 mm tubes. Place tubes in 20° H<sub>2</sub>O bath and let come to temp. Using flamed forceps, place 5 suture loops or cylinders, contaminated with *Cl. sporogenes* or *B. subtilis* and dried 24 hr

under vac., into each of the 6 tubes contg disinfectant, using 2-min intervals for seeding each tube. Five suture loops or cylinders can be placed into each tube within 5 sec. This seeding operation will take 10 min. After contact period specified for disinfectant has been achieved, remove suture loops or cylinders, using sterilized needle hook, from each tube of disinfectant to subculture medium or other subculture medium specified in **4.001(d)** (select medium contg most suitable neutralizer), placing 1 suture loop or cylinder per tube. Five cylinders can be removed within each 2 min interval. Flame transfer needle hook after each carrier has been transferred to subculture medium. After completing transfer, resubtransfer each suture loop or cylinder to fresh tube of thioglycolate medium and incubate 21 days at 37°. If no growth is observed after 21 days, heat-shock tubes 20 min at 80° and reincubate 72 hr at 37°. Report results as + (growth) or - (no growth) values.

Killing in 59 of 60 replicates on 1 carrier at diln and time specified is considered evidence of sporicidal efficacy against 1 test spore and for confidence level of 95%. Tests with both *B. subtilis* and *Cl. sporogenes*, using 30 replicates with each of 2 carriers specified to provide min. of 120 carriers, are required to presumptively support unqualified sporicidal claim or for presumptive evidence of sterilizing activity at concn, time, and conditions specified. For sporicidal claims, no more than 2 failures can be tolerated in this 120 carrier trial. For sterilizing claims, no failures can be tolerated.

#### Fungicidal Test (5)—Official Final Action

(Applicable for use with H<sub>2</sub>O-miscible type fungicides used to disinfect inanimate objects)

##### Using *Trichophyton mentagrophytes*

#### 4.018

##### Test Organism

Use as test fungus typical strain of *Trichophyton mentagrophytes* isolated from dermatophytosis of foot. Strain must sporulate freely on artificial media, presence of abundant conidia being manifested by powdery appearance on surface of 10-day culture, particularly at top of agar slant, and confirmed by microscopic examination. Conidia-bearing mycelium should peel easily from surface of glucose agar. Conidia of required resistance survive 10 min exposure at 20° to phenol diln of 1:70, but not to one of 1:60. Strain No. 640, ATCC No. 9533, is suitable.

#### 4.019

##### Culture Medium

Carry fungus on agar slants of following composition: Glucose 2%, Neopeptone (Difco) 1%, agar 2%, adjusted to pH 6.1–6.3. Use same culture medium to prep. cultures for obtaining conidial suspension, and use fluid medium of same nutrient composition (without agar) to test viability of conidia after exposure to fungicide.

#### 4.020

##### Care of Fungus Strain

Store stock culture of fungus on glucose agar slants at 2–5°. At intervals ≤3 months, transfer to fresh agar slants, incubate 10 days at 25–30°, and store at 2–5° until next transfer period. Do not use culture that has been kept at or above room temp. >10 days as source of inoculum for culture. (Cultures may be kept at room temp. to preserve strain and to inoculate cultures if transferred at intervals ≤10 days.)

#### 4.021

##### Preparation of Conidial Suspension

Prep. petri dish cultures by planting inoculum at center of agar plate and incubating culture at 25–30° for ≥10, but ≤15 days. Remove mycelial mats from surface of 5 agar plate

cultures, using sterile spatula or heavy flattened wire. Transfer to heat-sterilized glass tissue grinder, **4.016(e)**, and macerate with 25 mL sterile physiological NaCl soln (0.85% NaCl), or to heat-sterilized erlenmeyer contg 25 mL sterile saline with glass beads, and shake thoroly. Filter suspension thru sterile absorbent cotton to remove hyphal elements. Est. density of conidial suspension by counting in hemacytometer and store at 2–10° as stock spore suspension (125–155 × 10<sup>6</sup> conidia/mL) for ≤4 weeks for use in prep test suspensions of conidia. Stdze test conidial suspensions as needed by dilg stock spore suspension with physiological NaCl soln so that it contains 5 × 10<sup>6</sup> conidia/mL.

#### 4.022

##### Operating Technic

Prep. dilns of fungicide. (Tests are similar to those described in **4.003**.) Place 5 mL of each fungicide soln and of phenol control solns in 25 × 150 mm test-culture tubes, arrange in order of ascending dilns, place tubes in 20° H<sub>2</sub>O bath, and let come to temp. With graduated pipet, place 0.5 mL spore suspension in first tube of fungicidal soln, shake, and immediately replace in H<sub>2</sub>O bath; 30 sec later add 0.5 mL conidial suspension to second tube. Repeat at 30 sec intervals for each fungicidal diln. If more convenient, run test at 20 sec intervals. After 5, 10, and 15 min exposure to fungicide, remove sample from each conidia-fungicide mixt. with 4 mm loop and place in 10 mL glucose broth, **4.019**. To eliminate risk of faulty results due to possible fungistatic action, make subtransfers from the initial glucose broth subculture tubes to fresh tubes of glucose broth, using the 4 mm loop before incubation, or make initial subcultures in glucose broth contg either 0.05% Na thioglycolate, 1.5% iso-octylphenoxy-polyethoxy-ethanol, or mixt. of 0.07% lecithin (Azolectin, Associated Concentrates, Inc., 32–30 61st St, Woodside, NY 11377) and 0.5% polysorbate 80 (Tween 80), whichever gives lowest result. Incubate inoculated tubes at 25–30°. Read final results after 10 days, altho indicative reading can be made in 4 days.

*Note:* Highest diln that kills spores within 10 min is commonly considered as highest diln that could be expected to disinfect inanimate surfaces contaminated with pathogenic fungi.

#### Germicidal and Detergent Sanitizers (6)

##### Official Final Action

(Suitable for detg min. concn of chem. that can be permitted for use in sanitizing precleaned, nonporous food contact surfaces. Min. recommended starting concn is 2–4× this concn. Test also detg max. water hardness for claimed concns. As control, check accuracy of hard-water tolerance results with pure C<sub>14</sub> alkyl dimethyl benzyl NH<sub>4</sub> chloride (Onyx Chemical Co. 190 Warren St, Jersey City, NJ 07302) at 700 and 900 ppm hardness, and pure C<sub>16</sub> alkyl dimethyl benzyl NH<sub>4</sub> chloride (Cetalkonium Chloride, Sterling Chemical Co.), at 400 and 550 ppm hardness, expressed as CaCO<sub>3</sub>.)

#### 4.023

##### Reagents

(a) *Culture media*.—(1) *Nutrient agar A*.—Boil 3 g beef ext, 5 g peptone (Bacto or equiv.; special grades must not be used), and 15 g salt-free agar in 1 L H<sub>2</sub>O. Do not use premixed, dehydrated media. Tube, and autoclave 20 min at 121°. Use for daily transfer of test culture. (2) *Nutrient agar B*.—Prep. as above but use 30 g agar. Use for growing test cultures in French square bottles. (3) *Nutrient agar* (AOAC).—See **4.001(c)**. Use for prep stock culture slants.

(b) *Subculture media*.—(1) Use tryptone glucose ext agar (Difco), adding 25 mL stock neutralizer, (c)/L. (2) Tryptone glucose ext agar (Difco).

(c) *Neutralizer stock soln*.—Mix 40 g Azolectin (Associated Concentrates, 32–30 61st St, Woodside, NY 11377), 280 mL

polysorbate 80, and 1.25 mL phosphate buffer, (e); dil. with H<sub>2</sub>O to 1 L and adjust to pH 7.2. Dispense in 100 mL portions and autoclave 20 min at 121°.

(d) *Neutralizer blanks*.—For use with ≤200 ppm quaternary NH<sub>4</sub> compd. Mix 100 mL neutralizer stock soln, (c), 25 mL 0.25M phosphate buffer stock soln, (e), and 1675 mL H<sub>2</sub>O. Dispense 9 mL portions into 20 × 150 mm tubes. Autoclave 20 min at 121°.

(e) *Phosphate buffer stock soln*.—0.25M. Dissolve 34.0 g KH<sub>2</sub>PO<sub>4</sub> in 500 mL H<sub>2</sub>O, adjust to pH 7.2 with 1N NaOH, and dil. to 1 L.

(f) *Phosphate buffer dilution water*.—Add 1.25 mL 0.25M phosphate buffer stock soln, (e), to 1 L H<sub>2</sub>O and dispense in 99 mL portions. Autoclave 20 min at 121°.

(g) *Test organisms*.—Use *Escherichia coli* ATCC No. 11229 or *Staphylococcus aureus* ATCC 6538. Incubate 24 and 48 hr, resp. Maintain stock cultures on nutrient agar (AOAC), (a)(3), at refrigerator temp.

#### 4.024 Resistance to Phenol of Test Cultures

Det. resistance to phenol at least every 3 months by 4.001–4.005. Resistance of *E. coli* should be equiv. to that specified for *S. typhi* in 4.004 and that for *Staph. aureus* equiv. to that specified for this organism in 4.005.

#### 4.025 Apparatus

(a) *Glassware*.—250 mL wide-mouth erlenmeyers; 100 mL graduate; Mohr, serological, and/or bacteriological (APHA specification) pipets; 20 × 150 mm test tubes. Sterilize at 180° in hot air oven ≥2 hr.

(b) *Petri dishes*.—Sterile.

(c) *French square bottles*.—175 mL, borosilicate. Use of other containers will give variable results.

(d) *Water bath*.—Controlled at 25°.

#### 4.026 Preparation of Culture Suspension

From stock culture inoculate tube of nutrient agar A, 4.023(a)(1), and make ≥3 consecutive daily transfers (≤30), incubating transfers 20–24 hr at 35–37°. Do not use transfers >30 days. If only 1 daily transfer has been missed, no special procedures are required; if 2 daily transfers are missed, repeat with 3 daily transfers.

Prep. 175 mL French square culture bottles contg 20 mL nutrient agar B, 4.023(a)(2), autoclave 20 min at 121°, and let solidify with bottle in horizontal position. Inoculate culture bottles by washing growth from slant with 5 mL phosphate buffer diln H<sub>2</sub>O, 4.023(f), into 99 mL phosphate buffer diln H<sub>2</sub>O, and adding 2 mL of this suspension to each culture bottle, tilting back and forth to distribute suspension; then drain excess liq. Incubate 18–24 hr at 35–37°, agar side down. Remove culture from agar surface of 4 or more bottles, using 3 mL phosphate buffer diln H<sub>2</sub>O and glass beads in each bottle to suspend growth. Filter suspension thru Whatman No. 2 paper prewet with 1 mL sterile phosphate buffer, and collect in sterile tube.

(To hasten filtration, rub paper gently with sterile policeman.) Stdze suspension to give av. of  $10 \times 10^9$  organisms/mL by diln with sterile phosphate buffer diln H<sub>2</sub>O, 4.023(f).

If Lumetron colorimeter is used, dil. suspension in sterile Lumetron tube to give % T according to Table 4:02.

If McFarland nephelometer and BaSO<sub>4</sub> stds are used, select 7 tubes of same id as that contg test culture suspension. Place 10 mL of each suspension of BaSO<sub>4</sub>, prepd as indicated in Table 4:03, in each tube and seal tube. Stdze suspension to correspond to No. 4 std.

Table 4:03 Preparation of BaSO<sub>4</sub> Suspensions Corresponding to Bacterial Concentrations

Std No.	mL 2% BaCl <sub>2</sub> Soln	mL 1% H <sub>2</sub> SO <sub>4</sub> (v/v) Soln	Av. Bacterial Count/mL
1	4.0	96.0	$5.0 \times 10^9$
2	5.0	95.0	7.5
3	6.0	94.0	8.5
4	7.0	93.0	10.0
5	8.0	92.0	12.0
6	10.0	90.0	13.5
7	12.0	88.0	15.0

#### 4.027 Synthetic Hard Water

Prep. *Soln 1* by dissolving 31.74 g MgCl<sub>2</sub> (or equiv. of hydrates) and 73.99 g CaCl<sub>2</sub> in boiled distd H<sub>2</sub>O and dilg to 1 L. Prep. *Soln 2* by dissolving 56.03 g NaHCO<sub>3</sub> in boiled distd H<sub>2</sub>O and dilg to 1 L. *Soln 1* may be heat sterilized; *Soln 2* must be sterilized by filtration. Place required amt *Soln 1* in sterile 1 L flask and add ≥600 mL sterile distd H<sub>2</sub>O; then add 4 mL *Soln 2* and dil. to 1 L with sterile distd H<sub>2</sub>O. Each mL *Soln 1* will give a water equiv. to ca 100 ppm of hardness calcd as CaCO<sub>3</sub> by formula:

$$\text{Total hardness as ppm CaCO}_3 = 2.495 \times \text{ppm Ca} + 4.115 \times \text{ppm Mg}.$$

pH of all test waters ≤2000 ppm hardness should be 7.6–8.0. Check prepd synthetic waters chemically for hardness at time of tests, using following method or other methods described in 14th Ed. of *Standard Methods for the Examination of Water, Sewage, and Industrial Wastes*.

#### 4.028 Hardness Method

(a) *EDTA std soln*.—Dissolve 4.0 g Na<sub>2</sub>H<sub>2</sub>EDTA·2H<sub>2</sub>O and 0.10 g MgCl<sub>2</sub>·6H<sub>2</sub>O in 800 mL H<sub>2</sub>O and adjust by subsequent diln so that 1 mL of soln is equiv. to 1 mg CaCO<sub>3</sub> when titrd as in (c). Check EDTA soln after prepn or, if com. purchased, against CaCO<sub>3</sub> std at least every 2 months.

(b) *Calcium std soln*.—1 mL = 1 mg CaCO<sub>3</sub>. Weigh 1.00 g CaCO<sub>3</sub>, dried overnight or longer at 105°, into 500 mL erlenmeyer and add dil. HCl thru funnel until CaCO<sub>3</sub> is dissolved. Add 200 mL H<sub>2</sub>O, boil to expel CO<sub>2</sub>, and cool. Add few drops Me red indicator and adjust color to intermediate orange with dil. NH<sub>4</sub>OH or HCl as required. Transfer quant. to 1 L vol. flask and dil. to vol.

Table 4:02 Per Cent Light Transmission at Various Wavelengths Corresponding to Bacterial Concentrations

% Light Transmission with Filters, nm							Av. Bacterial Count/mL
370	420	490	530	550	580	650	
7.0	4.0	6.0	6.0	6.0	7.0	8.0	$13.0 \times 10^9$
8.0	5.0	7.0	7.0	7.0	8.0	9.0	11.5
9.0	6.0	8.0	8.0	8.0	9.0	10.0	10.2
10.0	7.0	9.0	9.0	9.0	11.0	11.0	8.6
11.0	8.0	10.0	10.0	10.0	12.0	13.0	7.7
13.0	9.0	12.0	12.0	12.0	13.0	15.0	6.7

(c) *Determination*.—Dil. 5–25 mL sample (depending on hardness) to 50 mL with H<sub>2</sub>O in erlenmeyer or casserole. Add 1 mL *buffer soln* (67.5 g NH<sub>4</sub>Cl and 570 mL NH<sub>4</sub>OH dild to 1 L with H<sub>2</sub>O), 1 mL *inhibitor* (5.0 g Na<sub>2</sub>S·9H<sub>2</sub>O or 3.7 g Na<sub>2</sub>S·5H<sub>2</sub>O dissolved in 100 mL H<sub>2</sub>O), and 1 or 2 drops *indicator soln* (0.5 g Chrome Black T in 100 mL 60–80% alcohol). Tit. with EDTA std soln slowly, stirring continuously, until last reddish tinge disappears from soln, adding last few drops at 3–5 sec intervals. Hardness as mg CaCO<sub>3</sub>/L = (mL std soln × 1000)/mL sample.

**4.029****Preparation of Samples**

Use composition declared or detd as guide to sample wt required for vol. sterile H<sub>2</sub>O used to prep. 20,000 ppm soln. From this stock diln, transfer 1 mL into 99 mL of the water to be used in test to give concn of 200 ppm. In making transfer, fill 1 mL pipet and drain back into stock soln; then refill, to correct for adsorption on glass. After mixing, discard 1 mL to provide 99 mL of the test water in **4.030**.

**4.030****Operating Technic**

Measure 99 mL water to be used in test, contg bactericide at concn to be tested, into chem. clean, sterile, 250 mL wide-mouth erlenmeyer and place in const temp. bath until it reaches 25°, or ≥20 min. Prep. duplicate flasks for each germicide to be tested. Also prep. similar flask contg 99 mL sterile phosphate buffer diln H<sub>2</sub>O, **4.023(f)**, as “initial numbers” control.

Add 1 mL culture suspension to each test flask as follows: Whirl flask, stopping just before suspension is added, creating enough residual motion of liq. to prevent pooling of suspension at point of contact with test water. Add suspension midway between center and edge of surface with tip of pipet slightly immersed in test soln. Avoid touching pipet to neck or side of flask during addn. Transfer 1 mL portions of this exposed culture to neutralizer blanks exactly 30 and 60 sec after addn of suspension. Mix well immediately after transfer.

For “numbers control” transfer, add 1 mL culture suspension to 99 mL sterile phosphate diln H<sub>2</sub>O in same manner. In case of numbers control, plants need be made only immediately after adding and mixing thoroly ≤30 sec. (It is advantageous to use milk pipets to add culture and withdraw samples.)

Plate from neutralizer tube to agar, using subculture medium **4.023(b)(1)** for quaternary NH<sub>4</sub> compds and **4.023(b)(2)** with numbers control. Where 0.1 mL portions are planted, use 1 mL pipet graduated in 0.1 mL intervals. For dilns to give countable plates, use phosphate buffer diln H<sub>2</sub>O, **4.023(f)**. For numbers control, use following diln procedure: Transfer 1 mL exposed culture (1 mL culture suspension transferred to 99 mL phosphate buffer diln H<sub>2</sub>O in H<sub>2</sub>O bath) to 99 mL phosphate buffer diln H<sub>2</sub>O, **4.023(f)**, (*diln 1*). Shake thoroly and transfer 1 mL *diln 1* to 99 mL phosphate buffer diln H<sub>2</sub>O, **4.023(f)**, (*diln 2*). Shake thoroly and transfer 1 mL *diln 2* to 99 mL phosphate buffer diln H<sub>2</sub>O (*diln 3*). Shake thoroly and transfer four 1 mL and four 0.1 mL aliquots from *diln 3* to individual sterile petri dishes.

For test samples, use following diln procedure: Transfer 1 mL exposed culture into 9 mL neutralizer, **4.023(d)**. Shake and transfer four 1 mL and four 0.1 mL aliquots to individual sterile petri dishes. For numbers control, use subculture medium **4.023(b)(2)**; for tests with quaternary NH<sub>4</sub> compds, use medium **4.023(b)(1)**. Cool agar to solidify, and then invert and incubate 48 hr at 35° before counting.

**4.031****Results**

To be considered valid, results must meet std effectiveness: 99.999% reduction in count of number of organisms within 30

sec. Report results according to actual count and % reduction over numbers control. Counts on numbers control for germicide test mixt. should fall between 75 and 125 × 10<sup>6</sup>/mL for % reductions to be considered valid.

**4.032****Sterility Controls**

- (a) *Neutralizer*.—Plate 1 mL from previously unopened tube.
- (b) *Water*.—Plate 1 mL from each type of water used.
- (c) *Sterile distilled water*.—Plate 1 mL.

After counting plates, confirm that surviving organisms are *E. coli* by transfer to brilliant green bile broth fermentation tubes or lactose broth and EMB agar; confirm *Staph. aureus* by microscopic examination.

**Germicidal Spray Products (7)—Official Final Action**

(Suitable for detg effectiveness of sprays and pressurized spray products as spot disinfectants for contaminated surfaces)

**4.033****Reagents**

Use culture media and reagents specified in **4.001**, **4.002(e)** and (f), and **4.007** except that test organism *Salmonella typhi* is not used.

Use as test organisms *Trichophyton mentagrophytes* ATCC No. 9533, prepd as in **4.021**, to which has been added 0.02 mL octylphenoxy-polyethoxy-ethanol (Triton X100, Rohm & Haas)/10 mL suspension to facilitate spreading, *Salmonella choleraesuis* ATCC No. 10708, **4.007(b)**, *Staphylococcus aureus* ATCC No. 6538, maintained as in **4.007(b)**, and *Pseudomonas aeruginosa* ATCC No. 15442, maintained as in **4.011**.

**4.034****Apparatus**

Use app. specified in **4.002** and **4.008**, and in addn:

- (a) *Capillary pipets*.—0.1 mL, graduated to deliver 0.01 mL. Sterilize in air oven 2 hr at 180°.
- (b) *Microscope slides*.—Non-corrosive, 25 × 25 mm (1 × 1”), or 18 × 36 mm glass slide. Sterilize by placing individual slides in petri dish matted with 2 pieces 9 cm filter paper (Whatman No. 2, or equiv.) in air oven 2 hr at 180°.
- (c) *Bacteriological culture tubes*.—Pyrex, 32 × 200 mm.
- (d) *Metal forceps*.—Sharp points, straight, 115 mm long.

**4.035****Operating Technic**

Thoroly shake 48 hr nutrient broth cultures of *S. choleraesuis* and *Staph. aureus* and let settle 10 min. With sterile capillary pipet or sterile 4.0 mm loop, transfer 0.01 mL culture onto 1 sq in. sterile test slide in petri dish and immediately spread uniformly over entire area. Cover dish immediately and repeat operation until 12 slides have been prepd for each organism. (Use 2 slides as control.) Dry all slides 30–40 min at 37°.

Spray 10 slides for specified time and distance. Hold each slide 10 min, drain off excess liq., and transfer slide to individual 32 × 200 mm tube contg 20 mL appropriate subculture medium, **4.001(d)**, with flamed forceps. Shake culture thoroly. If broth appears cloudy after 30 min, make subculture to fresh individual tubes of subculture broth. Transfer 2 unsprayed slides, as viability controls, to individual subculture tubes in same manner.

Incubate all tubes used for primary and secondary transfers 48 hr at 37°. Read as + (growth) or – (no growth). Killing of test organisms in 10 of 10 trials is presumptive evidence of disinfecting action.

Det. resistance of *S. choleraesuis* as in **4.003**; with *S. aureus* as in **4.005**; with *Ps. aeruginosa* as in **4.006**; and with *T. mentagrophytes* as in **4.018**.

If there is reason to believe that lack of growth in subtransfer tubes is due to bacteriostasis, inoculate all incubated subculture tubes with loop needle inoculation of respective test culture and reincubate. Growth of these inocula eliminates bacteriostasis as cause of lack of growth. If there is question as to possibility of contamination as source of growth in subculture tubes, make gram stains and/or subculture for identification, according to respective test culture.

If fungicidal activity as well as germicidal activity is involved, use test suspension of *T. mentagrophytes* spores, **4.021**, and prep. 12 slides, using 0.01 mL std spore suspension, spraying and subculturing exactly as above. Make subcultures in glucose broth, **4.019**, incubating 7 days at 25–30°.

#### Water Disinfectants for Swimming Pools (8) Official Final Action

(Suitable for presumptive evidence of acceptability of products for disinfecting swimming pool water)

#### 4.036

##### Test Culture Media

- (a) *Nutrient Agar A*.—See **4.023(a)(1)**.
- (b) *Nutrient Agar B* (Trypticase Soy Agar, BBL).—See **4.037(b)**.
- (c) *Nutrient Agar C*.—Prep. as in **4.001(c)**.

#### 4.037

##### Subculture Media

- (a) *Tryptone glucose extract agar* (Difco).—Dissolve 24 g in 1 L freshly distd H<sub>2</sub>O and heat to bp to dissolve completely. Autoclave 15 min at 121°. Use for plate counts of *E. coli* survivors.
- (b) *Trypticase soy agar* (BBL).—Suspend 40 g powder in 1 L H<sub>2</sub>O. Let stand 5 min and mix thoroly. Heat gently with occasional agitation and boil ca 1 min or until soln is complete. Autoclave 15 min at 121°. Let cool and reautoclave 15 min at 121°. Use for plate counts of *S. faecalis* survivors.
- (c) *Fluid thioglycolate medium* (Difco).—See **4.001(d)(2)**.
- (d) *Lactose broth* (Difco).—Dissolve 19 g in 1 L H<sub>2</sub>O. Dispense 10 mL portions into tubes with fermentation vials. Autoclave 15 min at 121°. Use for detg presence of *E. coli* survivors.
- (e) *Eosin methylene blue agar* (Difco).—Suspend 36 g in 1 L H<sub>2</sub>O and heat to bp to dissolve completely. Autoclave 15 min at 121°. Use for confirming *E. coli* survivors.
- (f) *S-F agar* (Difco).—Dissolve 36 g in 1 L H<sub>2</sub>O. Add 15 g agar and heat to bp to dissolve completely. Autoclave 15 min at 121°. Use for confirming *S. faecalis* survivors.

#### 4.038

##### Neutralizer Stock Solns

- (a) *Sodium thiosulfate soln*.—Dissolve 1 g Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> in 1 L H<sub>2</sub>O. Dispense in 100 mL portions and autoclave 20 min at 15 lb.
- (b) *Azolectin soln*.—See **4.023(c)**.
- (c) *Other preparations*.—Preps found to be suitable and necessary, depending upon nature of germicidal preps to be tested.

#### 4.039

##### Neutralizer Blanks

- (a) *With 0.6 ppm residual chlorine or less*.—Dil. 10 mL neutralizer stock soln, **4.038(a)**, with 90 mL sterile H<sub>2</sub>O. Dispense aseptically in 9 mL portions into sterile 25 × 150 mm tubes.
- (b) *With quaternary ammonium compounds and phenolic derivatives*.—Mix 10 mL neutralizer stock soln, **4.038(b)**, 2.5 mL 0.25M phosphate buffer stock soln, **4.040(a)**, and 167.5 mL H<sub>2</sub>O. Dispense in 9 mL portions into 20 × 150 mm tubes. Autoclave 20 min at 121°.
- (c) *Other preparations*.—Use dilns of **4.038(c)** as suitable.

#### 4.040

##### Reagents

- (a) *Phosphate buffer stock soln*.—0.25M. See **4.023(e)**.
- (b) *Phosphate buffer dilution water*.—See **4.023(f)**.
- (c) *Sodium thiosulfate std solns*.—(1) 0.1N. Dissolve exactly 24.820 g Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L. Stdze as in **50.038**.
- (2) 0.001N.—Dil. 10 mL soln (1) to 1 L with H<sub>2</sub>O.
- (d) *Starch indicator soln*.—See **6.005(f)**, except use few drops CHCl<sub>3</sub> instead of Hg as preservative.
- (e) *Sterile phosphate buffer stock solns*.—(1) Dissolve 11.61 g anhyd. K<sub>2</sub>HPO<sub>4</sub> in 1 L H<sub>2</sub>O and autoclave 20 min at 121°. (2) Dissolve 9.08 g anhyd. KH<sub>2</sub>PO<sub>4</sub> in 1 L H<sub>2</sub>O and autoclave 20 min at 121°.
- (f) *NaOCl stock soln*.—Approx. 5%. Store NaOCl stock soln in tightly closed bottle in refrigerator and det. exact available Cl at frequent intervals by As<sub>2</sub>O<sub>3</sub> titrn, **6.112**.
- (g) *Test organism*.—Use *Escherichia coli* ATCC 11229 and *Streptococcus faecalis* PRD (Microbiology Lab., Benefits and Field Services Div., EPA, Beltsville, MD 20705). Maintain, by monthly transfer, stock cultures of *E. coli* on *Nutrient Agar C*, **4.001(c)**, and *S. faecalis* on *Nutrient Agar B*, **4.037(b)**; store at 4–5°.

#### 4.041

##### Apparatus

- (a) *Glassware*.—500 mL wide-mouth erlenmeyers; 100 mL graduates; Mohr pipets; milk pipets; 20 × 150 mm tubes; Board of Health tubes; 200, 500, and 1000 mL vol. flasks. Wash in strong, fresh chromic acid cleaning soln, and fill and drain with H<sub>2</sub>O ≥3 times. Heat ≥2 hr at 180° in hot air oven.
- (b) *Petri dishes*.—Sterile.
- (c) *Water bath*.—Controlled at 20 or 25°.

#### 4.042

##### Preparation of Culture Suspension

From stock culture, inoculate tube Nutrient Agar A for *E. coli* and Nutrient Agar B for *S. faecalis*; make ≥3 consecutive daily transfers (≤30), incubating transfer 20–24 hr at 35–37°. Do not transfer >30 days. If only 1 daily transfer has been missed, no special procedures are required; if 2 daily transfers are missed, repeat with 3 daily transfers. Remove culture from agar surface, using 5 mL phosphate buffer diln H<sub>2</sub>O, **4.040(b)**. Transfer culture suspension to sterile centr. tube and centr. 1–2 min at speed necessary to settle agar particles. Transfer supernate to another sterile centr. tube and centr. to obtain complete sepn of cells. Discard supernate and resuspend cells in 5 mL buffer diln H<sub>2</sub>O. With *S. faecalis*, centr., discard supernate, and resuspend cells in 5 mL buffer diln H<sub>2</sub>O 2 addnl times. Finally, stdze suspension to give av. of 2.0 × 10<sup>8</sup> organisms/mL by diln with sterile phosphate diln H<sub>2</sub>O.

If Lumetron is used, dil. suspension in sterile Lumetron tube to give % T according to Table 4:04. Make serial diln plate count of each culture suspension before use, using phosphate buffer diln H<sub>2</sub>O, **4.040(b)**, and subculture medium, **4.037(a)**, with *E. coli*, and (b) with *S. faecalis*. Incubate diln plates in inverted position 48 hr at 35–37°. Use Quebec Colony Counting Chamber and report results in terms of number of bacteria/mL suspension.

Table 4:04 Per Cent Light Transmission at Various Wavelengths Corresponding to Bacterial Concentrations

	% Light Transmission with Filter, nm						Av. Bacterial Count /mL
	370	420	490	530	580	650	
<i>E. coli</i>	90	88	89	88	91	92	2.0 × 10 <sup>8</sup>
<i>S. faecalis</i>	86	82	85	85	87	89	2.0 × 10 <sup>8</sup>

Count of  $2.0 \times 10^6$  is desired so that 1 mL test culture suspension + 199 mL test soln will provide soln contg  $1 \times 10^6$  organisms/mL. Permitted variation in test culture suspension is +500,000 and -100,000/mL of 200 mL test soln. Use actual count for calcg zero time count in later tests.

**4.043****Determining Chlorine Demand of Freshly Distilled Test Water**

Place 200 mL  $H_2O$  in each of five 500 mL erlenmeyers. To flasks 1-5, resp., add 0.025, 0.05, 0.075, 0.1, and 0.15 mL of 200 ppm available Cl prep'd from NaOCl soln, **4.040(f)**. Shake each flask, and let stand several min. Add crystal KI and 1 mL HOAc, and swirl. Add 1 mL starch soln, **4.040(d)**. Flask showing perceptible blue indicates Cl demand has been satisfied.

**4.044****Operating Technic**

Place ca 600 mL freshly sterilized distd  $H_2O$  in 1 L vol. flask. Add ca 1.5-3.0 mL  $K_2HPO_4$  buffer, **4.040(e)(1)**, and 0.5 mL  $KH_2PO_4$ , **4.040(e)(2)**, and dil. to 900 mL. Add enough NaOCl from suitable diluent of std stock soln, **4.040(f)**, to satisfy Cl demand of 1 L test  $H_2O$ , **4.043**, and to provide ca 0.6 ppm residual available Cl. Dil. to vol. (Example: If Cl demand of  $H_2O$  is 0.1 ppm, add 3.5 mL of 200 ppm soln of available Cl made from std stock NaOCl soln, **4.040(f)**, and dil. to vol. This should provide soln with ca 0.6 ppm residual available Cl at pH  $7.5 \pm 0.1$ .) Transfer 199 mL of this test soln to each of three 500 mL erlenmeyers and place in  $H_2O$  bath at either 20 or 25°. Let come to temp.

To first flask, add 1 mL boiled distd  $H_2O$  and det. residual available Cl as follows: Add small crystal KI and 1 mL HOAc; then add 1 mL starch soln, **4.040(d)**. Blue soln indicates presence of Cl. Titr. with 0.001N  $Na_2S_2O_3$ , **4.040(c)(2)**, until color disappears; mL 0.001N  $Na_2S_2O_3 \times 0.1773$  = ppm residual available Cl. This represents available Cl at 0 time in test. Result should be  $\geq 0.58$  but  $\leq 0.62$ .

To each of remaining flasks add 1 mL test culture suspension, **4.042**, as follows: Swirl flask, stopping just before suspension is added, to create enough centrifugal motion to prevent pooling of suspension at point of contact with test  $H_2O$ . Add suspension midway between center and edge of liq. surface, immersing tip of pipet slightly below surface of  $H_2O$ . Avoid touching pipet to neck or side of test flask during operation.

From one of these 2 flasks transfer 1 mL aliquots to neutralizer blanks, **4.039(a)**, after intervals of 0.5, 1, 2, 3, 4, 5, and 10 min. Shake neutralizer blank thoroughly immediately after adding sample. Prep. serial diln plate counts from neutralizer blanks, using phosphate buffer diln  $H_2O$ , **4.040(b)**, and subculture medium, **4.037(a)** for *E. coli*, and (b) for *S. faecalis*.

After prep'd diln plate counts, inoculate 5 lactose broth tubes, **4.037(d)**, with 1.0 mL aliquots from each neutralizer blank tube for each time interval when *E. coli* is used as the test organism, and 5 thioglycolate broth tubes, **4.037(c)**, with 1.0 mL aliquots from each neutralizer blank tube for each time interval when *S. faecalis* is test organism.

Incubate all diln plates in inverted position and subculture tubes 48 hr at 37°. Use Quebec Colony Counting Chamber in reading diln plates and report results in terms of number of surviving bacteria/mL test  $H_2O$ . Absence of colony growth on diln plates and absence of growth in all 5 lactose or thioglycolate tubes, as case may be, is necessary to show complete kill of test organism.

Immediately after transferring 10 min interval sample from second flask to neutralizer blank tube, remove third flask from  $H_2O$  bath and det. residual available Cl exactly as specified for first flask. Results should represent residual available Cl present at 10 min exposure interval. To be acceptable, concn of available

Cl in this flask should be  $>0.4$  ppm. Results in Cl control test described above should show complete kill of *E. coli* and *S. faecalis* within 0.5 min.

With unknown sample, prep. 2 flasks contg 199 mL each of soln at concn recommended or to be studied, using Cl demand-free, unbuffered, freshly distd  $H_2O$  previously prep'd in 1 L vol. flask where Cl demand, as det'd above, has been satisfied by addn of NaOCl soln. Place flasks in  $H_2O$  bath at 20 or 25°; let come to temp. Inoculate 1 flask with 1 mL std test culture suspension of *E. coli* and other with 1 mL std test culture suspension of *S. faecalis*. Subculture at exactly same time intervals and in same manner used with NaOCl control except vary composition of neutralizer blank depending upon nature of chem. or mixt. of chems under investigation. For example, mixt. of Cl-contg chem. and quaternary  $NH_4$  comp'd would require special neutralizer blank prep'd by using both neutralizer stock solns, **4.038(a)** and (b).

Where no concn of chem. under study has been recommended and objective of study is to det. concn of unknown necessary to provide result equiv. to that obtained with Cl control std, use series of three or four 500 mL flasks contg 199 mL of various concns of chem. and 1 mL std'd culture suspension with each test organism. Report results as log (number of survivors) at each time interval both for Cl controls and various concns of unknown under test.

Lowest concn of unknown germicide or germicidal mixt. providing results equiv. to those obtained with NaOCl as Cl std is considered lowest concn which could be expected to provide acceptable disinfecting activity in swimming pool water.

**Tuberculocidal Activity (9)—Official Final Action**

(Suitable for detg max. tuberculocidal diln of disinfectants used on inanimate surfaces)

**I. Presumptive In Vitro Screening Test Using Mycobacterium smegmatis****4.045****Reagents**

(a) *Test organism*.—*Mycobacterium smegmatis* (PRD No. 1) (available from Microbiology Lab., Benefits and Field Services Div., EPA, Beltsville, MD 20705). Maintain on nutrient agar slants by monthly transfers. Incubate new stock transfer 2 days at 37°; then store at 2-5°. From stock culture inoculate tubes of Proskauer-Beck broth, (b)(1), incubate 48 hr in slanting position, carry 30 days, using 48 hr transfers, and use these 48 hr cultures to start test cultures. Inoculate 1 or 2 tubes of Proskauer-Beck broth. Incubate 6-7 days at 37°. Incubate tubes 48 hr in slanting position to provide max. surface aeration and then in upright position 4-5 days. Add 1.5 mL sterile 2.0% Bacto-Gelatin soln and homogenize culture with sterilized glass tissue grinder, **4.016(e)**. Adjust to 20% T at 650 nm with sterile Proskauer-Beck broth for use in testing.

(b) *Culture media*.—(1) *Modified Proskauer-Beck broth*.—Dissolve 2.5 g  $KH_2PO_4$ , 5.0 g asparagine, 0.6 g  $MgSO_4 \cdot 7H_2O$ , 2.5 g Mg citrate, 20.0 mL glycerol, 0.0046 g  $FeCl_3$ , and 0.001 g  $ZnSO_4 \cdot 7H_2O$  in 1 L  $H_2O$ . Adjust to pH 7.2-7.4 with 1N NaOH. Filter thru paper, place 10 mL portions in sep. 20  $\times$  150 mm tubes, and sterilize 20 min at 121°. Use for propagating 48 hr test starter cultures and 6-7 day test cultures.

(2) *Subculture media*.—Use (1) with addn of suitable neutzg agents such as purified lecithin (Azolectin) or Na thioglycolate, where necessary.

(3) *Nutrient agar*.—Prep. as in **4.001(c)**. Use to maintain stock culture.

(4) *Sterile distilled water*.—See **4.007(d)**.

**4.046****Apparatus**

(a) *Glassware, water bath, transfer loops and needles, and petri dishes.*—See 4.008(a), (b), (c), and (e).

(b) *Carriers.*—See 4.016(g).

**4.047****Operating Technic**

Transfer 20 sterile Penicylinder carriers, using flamed nichrome wire hook, into 20 mL 6–7 day homogenized stdzd broth culture, 4.045(a), in sterile 25 × 150 mm medicant tube. After 15 min contact, remove cylinders and place on end in vertical position in sterile petri dish matted with filter paper, 4.008(e). Cover and place in incubator at 37° and let dry ≥20 min but ≤60 min. This will provide dried test carriers in groups of 20 in individual petri dishes. With each group of 20 carriers, add 1 dried cylinder at 30 sec intervals to each of 20 tubes contg 10 mL diln of germicide to be tested (at 20° in H<sub>2</sub>O bath). Flame lips of medicant and subculture tubes. Immediately after placing carrier in medicant tube, swirl tube 3 times before placing it back in H<sub>2</sub>O bath. (Thus, by time 20 tubes have been seeded, 9 min and 30 sec have elapsed, leaving 30 sec interval prior to subculturing series at 10 min exposure for each carrier. The 30 sec interval between transfers allows adequate time for flaming and cooling transfer hook and making transfer in manner so as to drain all excess medicant from carrier.) Transfer carrier to 10 mL subculture media, 4.045(b)(2). Shake all subculture tubes thoroly and incubate 12 days at 37°. Report results as + (growth) or – (no growth). Where there is reason to suspect that results may be affected by bacteriostatic action of medicant carried over in subculture tubes, use suitable neutralizer in subculture media.

Make ≥30 carrier exposures at each of 3 relatively widely spaced dilns of germicide under test between no response and total response diln levels. Calc. % of carriers on which organism is killed at each diln. Using log-% probit paper (3 cycle logarithmic normal No. 32.376, Codex Book Co., Inc., Norwood, MA 02062), locate % kill points on diln lines employed (log scale). Draw best fitting straight line thru these 3 points and extend to intercept 99% kill line. Read diln line (log scale) at point of intercept. This is presumed 95% confidence end point for product. (Do not use presumptive test organism for checking validity of this presumptive end point.)

## **II. Confirmative In Vitro Test for Determining Tuberculocidal Activity**

**4.048****Reagents**

(a) *Culture media.*—(1) *Modified Proskauer-Beck medium.*—Prep. as in 4.045(b)(1), and in addn, place 20 mL portions in 25 × 150 mm tubes. Use 10 mL portions for daily transfers of test cultures and 20 mL portions for subculturing porcelain cylinders.

(2) *Middlebrook 7H9 Broth Difco A.*—Dissolve 4.7 g in 900 mL H<sub>2</sub>O contg 2 mL glycerol and 15.0 g agar. Heat to bp to dissolve completely. Distribute in 180 mL portions and autoclave 15 min at 121°. To each 180 mL sterile medium at 45°, add 20 mL Middlebrook ADC Enrichment (Difco) under aseptic conditions and distribute in 10 mL portions in sterile 20 × 150 mm tubes. Slant. Use to maintain test culture.

(3) *Middlebrook 7H9 Broth Difco B.*—Dissolve 4.7 g in 900 mL H<sub>2</sub>O contg 2 mL glycerol and 1.0 g agar. Heat to bp to dissolve completely. Distribute in 18 mL portions in 25 × 150 mm tubes, and autoclave 15 min at 121°. To each 18 mL sterile medium at 45° add 2 mL Middlebrook ADC Enrichment under aseptic conditions. Use to subculture for survival.

(4) *Kirchners Medium Difco.*—Dissolve 13.1 g in 1 L H<sub>2</sub>O contg 20 mL glycerol and heat to bp to dissolve completely. Distribute

in 18 mL portions in 25 × 150 mm tubes and autoclave 15 min at 121°. To each 18 mL sterile medium at 50–55° add 2 mL Middlebrook ADC Enrichment under aseptic conditions. Use to subculture for survival.

(5) *TB Broth Base Difco (without polysorbate 80).*—Dissolve 11.6 g in 1 L H<sub>2</sub>O contg 50 mL glycerol and 1.0 g agar. Heat to bp to dissolve completely. Distribute in 18 mL portions in 25 × 150 mm tubes, and autoclave 15 min at 121°. To each 18 mL sterile medium at 50° add 2 mL Dubos Medium Serum (Difco) under aseptic conditions. Use to subculture for survival.

(b) *Test organism.*—*Mycobacterium bovis* (BCG) (available from ITR Biomedical Research, University of Illinois Medical Center, 904 W Adams St, Chicago, IL 60607). Maintain stock cultures on culture medium (a)(2) by monthly or 6 weeks transfer. Incubate new stock transfer 15–20 days at 37° until sufficient growth is indicated; then store at 2–5°. From stock culture, inoculate tube of culture medium (a)(1) and incubate 21–25 days at 37°. Shake gently once daily for 9 days; then allow to remain quiescent until 21–25th day. Make daily transfers from 21 day cultures. Transfer culture to heat-sterilized glass tissue grinder, add 1.5 mL sterile 2% Bacto-gelatin soln (Difco), grind, and dil. with culture medium (a)(1) to give 20% T at 650 nm. Use to inoculate porcelain cylinders used in test. Tests will be satisfactory only when organism is killed on all 10 carriers by aq. phenol (1+50) and shows survival after exposure to aq. phenol (1+75) control. Prep. dilns from 5% std phenol soln, 4.002(f).

(c) *Sterile distilled water.*—See 4.007(d).

(d) *Sterile normal horse serum without preservative.*—Difco Laboratories or Microbiological Associates, 4733 Bethesda Ave, Bethesda, MD 20014.

**4.049****Apparatus**

(a) *Glassware, water bath, transfer loops and needles, and petri dishes.*—See 4.008(a), (b), (c), and (e).

(b) *Carriers.*—See 4.016(g).

**4.050****Operating Technic**

Soak ring carriers overnight in 1N NaOH; rinse with tap H<sub>2</sub>O and then with distd H<sub>2</sub>O until distd H<sub>2</sub>O is neut. to phthln; then rinse twice with distd H<sub>2</sub>O. Place clean ring carriers in multiple of 10 or 20 in capped erlenmeyer or 20 × 150 mm tubes. Autoclave 20 min at 121°, cool, and hold at room temp. Transfer 10 sterile ring carriers, using flamed wire hook, into enough (ca 15–20 mL) 21–25 day stdzd test culture, 4.048(b), in 25 × 150 mm medication tube. After 15 min contact period, remove cylinders, using flamed wire hook, and place on end in vertical position in sterile petri dish matted with filter paper, 4.008(e). Cover, place in incubator at 37°, and let dry ≥20 min but ≤60 min.

Let 10 tubes contg 10 mL use-diln germicide sample to be tested come to 20° in H<sub>2</sub>O bath and add 1 contaminated cylinder carrier at either 30 sec or 1 min intervals to each tube. Immediately after placing carrier in medication tube, swirl 3 or 4 times before placing tube back in bath. (Thus, by time 10 tubes have been seeded, 9 min will have elapsed, plus 1 min interval before transfer of first carrier in series to individual tube of 10 mL serum, 4.048(d), or 10 mL neutralizer blank, 4.023(d), if 1 min intervals are used. This interval is constant for each tube with prescribed exposure period of 10 min. Interval between transfers allows adequate time for flaming and cooling wire hook and making transfer in manner so as to drain all excess medication from carrier.) Transfer carrier to 10 mL serum, 4.048(d), after exactly 10 min contact. Shake tube contg carrier in serum thoroly and place carrier in tube contg 20 mL broth, 4.048(a)(1). From

same tube, take 2 mL portions serum and place in any 2 of the subculture media, 4.048(a)(3), (4), (5). Repeat this with each of the 10 carriers. Incubate 1 tube of each subculture medium with 2 mL sterile serum as control. Where there is reason to suspect that germicide to be tested may possess bacteriostatic action, use suitable neutralizer in lieu of serum. Shake each subculture tube thoroly, incubate 60 days at 37°, and report results as + (growth) or - (no growth). If no growth or only occasional growth is observed in subculture, incubate addnl 30 days before making final reading. Max. diln of germicide which kills test organism on the 10 carriers, and no growth in each of the 2 mL aliquots for 2 extra media, represents max. safe use-diln for practical tuberculocidal disinfection.

#### Bacteriostatic Activity of Laundry Additives (10) Official First Action

(Applicable to antimicrobial products, recommended for use during laundering operations, which are intended to provide residual bacteriostatic treatment to laundered fabric. Method includes treatment of fabric with product and subsequent bacteriostatic testing of treated fabric.)

#### 4.051

#### Reagents

- (a) *Culture media*.—(1) *Nutrient broth*.—See 4.001(a).
- (2) *Nutrient agar A*.—See 4.001(c). Use for monthly transfer of stock cultures.
- (3) *Nutrient agar B*.—Boil 3 g beef ext, 5 g peptone (Anatone), 8 g NaCl, and 10 g agar (Difco) in 1 L H<sub>2</sub>O. Transfer 100 mL portions to erlenmeyers, and autoclave 20 min at 121°. Use for agar plate tests to evaluate bacteriostatic activity of treated fabric. See also (c).
- (b) *Test organisms*.—Use *Staphylococcus aureus* ATCC No. 6538 and *Klebsiella pneumoniae*, aberrant ATCC No. 4352 (formerly *Escherichia coli*), and maintain as in 4.002(e).
- (c) *2,3,5-Triphenyl tetrazolium chloride*.—Use as optional biological indicator. With *S. aureus*, use 0.15% soln; with *K. pneumoniae*, aberrant, use 0.25% soln. Autoclave each 20 min at 121°. Apply as in 4.054.
- (d) *Alkaline nonionic wetting agent*.—Prep. aq. soln contg 0.5% alkyl phenol polyglycol ether wetting agent and 0.5% Na<sub>2</sub>CO<sub>3</sub>. Use to scour test fabric.

#### 4.052

#### Apparatus

- (a) *Test fabric*.—80 × 80 threads/sq in. plain weave cotton print cloth, completely desized, bleached, and without bluing or optical brighteners (available from Test Fabrics, Inc., 55 Van Dam St, New York, NY 10013). Scour before use by boiling ca 300 g 1 hr in 3 L H<sub>2</sub>O contg 1.5 g nonionic wetting agent and 1.5 g Na<sub>2</sub>CO<sub>3</sub>. Then rinse fabric, first in boiling H<sub>2</sub>O and then in cold H<sub>2</sub>O, until all visual traces of wetting agent are removed. Air-dry and cut into long strip 5 cm (2") wide and weighing exactly 15 g.
- (b) *Stainless steel spindle*.—Fabricate from single continuous piece of stainless steel wire 1/16" diam. and bent to contain 3 horizontal extensions 5 cm (2") long connected by 2 vertical sections ca 5 cm (2") long. Shape so that vertical sections form 150° angle, and sharpen free ends of 2 outer horizontal extensions to point (see Fig. 4:02). Use as carrier for test fabric. Primary objective of spindle is to prevent wadding or lodging of test fabric during agitation in exposures to test chem. solns.
- (c) *Exposure chamber*.—Clean, dry 1 pt Mason jar with rubber washer or gasket and metal screw cap.
- (d) *Agitator*.—Device to rotate Mason jar thru 360° vertical orbit of 10–20 cm (4–8") diam. at 45–60 rpm for 5 min. Launderometer or Tumble Jar described in AATCC70 B-1967, 43, B154, B155, or ASTM D583-63 is adequate.

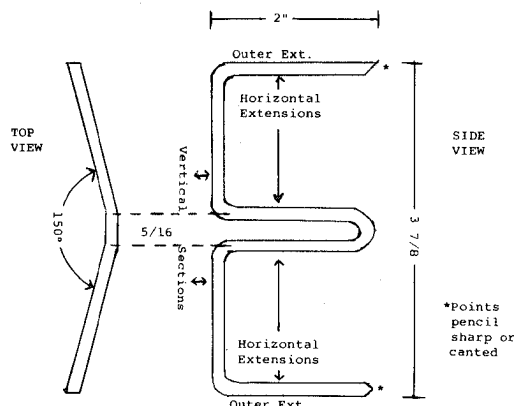

FIG. 4:02—Stainless steel spindle for winding test fabric

- (e) *Water bath*.—Thermostatically controlled at 25°.
- (f) *Petri dishes*.—Sterile, 100 × 15 mm.
- (g) *Glassware*.—See 4.002(a).
- (h) *Transfer loops and needles*.—See 4.002(d).

#### 4.053

#### Preparation of Fabric

- (a) *Fabric mounting*.—Pierce one end of prescoured, 15 g test fabric strip and secure onto an outer horizontal extension of test spindle; then wind strip around 3 horizontal extensions with enough tension to obtain 12 (but not 13) entire laps. Secure final end of test fabric strip to previous laps with stainless steel safety pin.
- (b) *Fabric treatment with product*.—Dil. product as directed to 75 mL (most frequently, use directions are based on dry wt of laundry fabric equiv. to 15 g test fabric), add to Mason jar (exposure chamber), and maintain in H<sub>2</sub>O bath at 25°. Add addnl materials to Mason jar as required by use directions for product. These are:
  - (1) *Product recommended as final rinse additive in industrial laundering operation*.—Add no addnl materials; 5:1 (v/w) treatment product soln to dry fabric ratio is representative of industrial laundering operations.
  - (2) *Product recommended as final rinse additive in home or coin-operated laundering operations*.—Add 150 mL H<sub>2</sub>O to Mason jar. Resultant 10:1 (v/w) treatment product soln to dry fabric ratio is representative of home and coin-operated laundering operations.
  - (3) *Product recommended as final rinse additive in both industrial and home laundering operations*.—Prep. 2 jars contg product soln according to (1) and (2) so that 2 test fabric strips may be treated at different treatment product soln to dry fabric ratios (5:1 and 10:1 (v/w)).
  - (4) *Product recommended as final rinse additive and described as compatible with adjunct chemicals which may be used in this cycle (sours, bleaches, optical brighteners, softeners, etc.)*.—Prep. so that required vol. of product treatment soln contains adjunct chemicals according to description and amts specified on product label or advertising literature.

#### 4.054

#### Operating Technic

Place test spindle with test fabric in Mason jar contg product soln. Secure rubber gasket and Mason jar cap, remove from H<sub>2</sub>O bath, place jar in agitator, and rotate 5 min. Addnl manipulation with test spindle is required if use directions do not specify addn of product in final rinse phase of laundry cycle. In this instance, to det. durability of antimicrobial agent in fabric, execute 3 rinse operations as follows: Immediately after end of

initial 5 min agitation, drain treatment soln from Mason jar and replace with 100 mL H<sub>2</sub>O. Secure Mason jar contg test spindle, return to agitator, and rotate 2 min. Repeat operation twice more.

Following all required fabric treatment operations, remove test spindle from Mason jar and unwind test fabric strip from spindle. Let test fabric strip air dry with long axis of strip in horizontal position.

When test strip is dry, remove 1 sq in. bacteriological test samples. Five test samples are required for single bacteriostatic test against 1 test organism. In each such instance, at least 2 test samples must be removed from middle 20% of length of test strip.

Perform bacteriostatic agar plate tests as follows: Prep. 5 replicate plates in each test for each organism. Sep. inoculate flasks contg 100 mL sterile, liq. ( $\leq 40^\circ$ ) nutrient agar B with 1 mL 24 hr nutrient broth culture of *S. aureus* and *K. pneumoniae*, aberrant. Immediately thereafter, if desired, add 1 mL appropriate soln of 2,3,5-triphenyl tetrazolium chloride to inoculated nutrient agar B. Vigorously swirl contents of erlenmeyers to ensure complete mixing. Add 10 mL portions of inoculated agar to 100 mm sterile petri dishes, distribute evenly, and let cool and harden. As soon as plates harden, implant single 1 sq in. treated fabric test sample on center of 1 test agar plate surface. Using blunt forceps, press each fabric test sample onto agar surface to ensure complete and uniform contact. Incubate test plates 48 hr at 37°. If desired, test plates may be refrigerated 18–20 hr before incubation. Following incubation, examine test plates to det. presence or absence of zones of inhibition along each side of test fabric sample.

#### 4.055

#### Interpretation

Use clear zone of inhibition adjacent to each side of test fabric sample as index of bacteriostatic activity. Size of zone is not

considered important, but zone is required to extend along entire edge to be acceptable. Score zone of inhibition along single side of sq test fabric samples as 1, so that for 5-replicate plate test, a score of 20 shows that bacteriostasis occurs along all 4 sides of each sample. Total score of 18/20 sides demonstrating bacteriostasis is required for effective demonstration of residual bacteriostatic activity of laundry fabric treated with antimicrobial laundry additive product during laundering operation. Unless qualified residual bacteriostatic claim is made, residual treatment must be bacteriostatic against both *S. aureus* and *K. pneumoniae*, aberrant.

## 5. Hazardous Substances

### PAINT

#### Lead (7)—Official Final Action

5.001

#### Reagents and Apparatus

(a) *Lead std solns.*—(1) *Stock soln.*—1 mg Pb/mL 1% HNO<sub>3</sub>. Dissolve 159.9 mg Pb(NO<sub>3</sub>)<sub>2</sub> in HNO<sub>3</sub> (1+99) and dil. to 100 mL with HNO<sub>3</sub> (1+99). (2) *Intermediate soln.*—300 µg/mL dil. HNO<sub>3</sub>. Dil. 15 mL stock soln to 50 mL with 0.5 mL HNO<sub>3</sub> and H<sub>2</sub>O. (3) *Working solns.*—To each of seven 100 mL vol. flasks contg 1 mL HNO<sub>3</sub>, add resp. 0, 1, 2, 3, 4, 5, and 6 mL intermediate soln and dil. to vol. with H<sub>2</sub>O (0, 3, 6, 9, 12, 15, and 18 µg Pb/mL).

(b) *Atomic absorption spectrophotometer.*—With Pb hollow cathode lamp and 4" single slot or 3 slot Belling burner head, capable of detecting 0.5 µg Pb/mL, such as Perkin-Elmer Model 403. Operating conditions: 283.3 nm, 0.7 nm band width slit, recorder response (if used) 0.25–1 sec time constant, air-C<sub>2</sub>H<sub>2</sub> flame, with gas flows adjusted according to directions of manufacturer.

(c) *Heater for digestion.*—Drill 7.5 cm Al block to hold ≥16 test tubes, 16 × 150 mm. Place on hot plate capable of maintaining medium at 160–170° (Corning PC 35, or equiv.). Sand bath may be used instead of Al block.

(d) *Boiling chips.*—Unglazed boiling chips, 1.5 mm diam., Pb-free.

5.002

#### Determination of Solids

Thoroughly mix samples manually for 10 min or mech. for 5 min. Accurately weigh 0.3–0.4 g into weighed Al dish, 63 mm diam. Add 3–5 mL hexane or pet ether to oil-based paints or H<sub>2</sub>O to latex paints and swirl to disperse. Warm on hot plate while swirling until solv. has evapd and film is formed. Heat in oven 4 hr at 105°, cool, and weigh.

% Solids = g dried sample × 100/g sample.

5.003

#### Determination of Lead

Introduce ca 0.6 g (0.3 mL) thoroughly mixed sample near bottom of 16 × 150 mm test tube with syringe and weigh accurately. Add 5±0.2 mL HNO<sub>3</sub> and 2 boiling chips to each, including blanks. Place in block or bath at 90–100° so that liq. surface is slightly above heated surface. (Use hood.) After initial fuming has subsided, increase temp. until vapors are condensing in top 1–2 cm of tube (bath temp., 160–170°) and maintain at this temp. 3 hr. Cool to 50–60°, transfer to 25 mL vol. flask, including chips and any ppt, and rinse with four 4 mL portions H<sub>2</sub>O, transferring as much residue as possible. Dil. to vol. with H<sub>2</sub>O and let settle 0.5–1 hr. Floating residue may be removed by aspiration thru disposable pipet.

Aspirate solns and stds into AA spectrophotometer, avoiding introduction of ppt. If A of sample is greater than highest std, dil. sample and re-aspirate. Det. µg Pb/mL from std curve.

% Pb in paint solids = (µg Pb/mL) × F × 10<sup>-2</sup>/

(g sample × % solids in sample)

F (diln factor) = 1/[(1/25) (b/c) (d/e) ...],

where 25 = vol. original sample digest, b = aliquot of original 25 mL dild to c mL; d = aliquot of c (mL) dild to e mL; etc. For dry paint films, % solids in sample = 100.

### PREPARATIONS CONTAINING FLUORIDES

#### Fluoride (2)—Official Final Action

5.004

#### Apparatus

(a) *pH meter.*—With expanded mv scale (digital Model 110, Corning Scientific Instruments, Medfield, MA 02052, or equiv.), fluoride ion-selective electrode (Model 94-09, Orion Research Inc., 11 Blackstone St, Cambridge, MA 02139, or equiv.), and single junction ref. electrode, plastic sleeve-type (Model 90-01, Orion Research Inc., or equiv.).

(b) *Magnetic stirrer.*—With Teflon-coated stirring bar. Use asbestos or foam mat to insulate sample from motor heat.

(c) *Beakers.*—4.5 oz (135 mL), polypropylene, or equiv.

(d) *Graph paper.*—Linear or semi-antilog, vol. corrected No. 90-00-90 Gran's plot paper (Orion Research Inc., or equiv.).

5.005

#### Reagents

(a) *Buffer soln.*—pH 6.0. Add 77.0 g NH<sub>4</sub>OAc and 0.452 g NH<sub>4</sub> citrate to 1 L H<sub>2</sub>O. Adjust to pH 6.0 with HOAc.

(b) *Fluoride std soln.*—1 mg F/mL. Prep. 2.2108 g NaF (reagent grade, dried 4 hr at 105°)/L buffer soln. (*Caution:* See 51.084.) Store in leakproof plastic bottles. Compare with 1 mg F/mL soln prepd from USP Ref. Std; equiv. reading of ±1 mv is satisfactory.

5.006

#### Determination

(Stir all solns constantly at same rate thruout titrns. Let electrodes equilibrate ≥2 min before addn of F std soln and 30 sec after each addn of F std soln.)

(a) *Blank.*—Record mv values (E') of 100 mL buffer soln after addn of 4 mL std F soln from 10 mL buret and after each addnl mL up to 10 mL. (Preliminary mv values will not fall on linear range of response curve.) Vol. std soln added = V'.

(b) *Samples.*—Est. molarity of samples from direct reading. Dil. samples, if necessary, to ca 0.001M F. Transfer 50 mL sample soln to beaker and add 50 mL buffer soln. Record initial mv reading, using expanded scale (E<sub>0</sub>). If initial reading is <−50 mv, soln is too concd. Dil. sample to avoid asymptotic slope. Record mv values (E) after each mL F std soln is added up to 10 mL. Rinse electrodes with H<sub>2</sub>O between samples. Vol. std soln added = V.

5.007

#### Calculations

(a) *Linear graph paper.*—For each addn of F std soln and corresponding E value, calc. for blank:

$$Z' = \text{antilog} [\log(V_0 + V') - 0.017(E')],$$

where V<sub>0</sub> is original vol. soln to which F std soln was added (100mL) and E' is treated algebraically (+ or − as read). Plot Z' against mL (mg) F std soln added and extrapolate to intersection of mL (mg) F axis to obtain mL (mg) F in blank, V<sub>e</sub>'. In graph, assign horizontal axis to mL (mg) F, with 0 at center and mL (mg) F increasing in both directions to left and right. Assign Z values to vertical axis. Plot actual readings of mL (mg) F on right portion of horizontal axis so that extrapolation will fall on left portion of axis.

Similarly, for original readings and each addn of F std soln and corresponding  $E$  value, calc. for sample:

$$Z = \text{antilog} [\log(V_0 + V) - 0.017(E)],$$

where  $V_0$  is original vol. soln to which F std soln was added (100 mL). Plot  $Z$  against mL (mg) F std soln on same graph as blank and extrapolate to intersection of mL (mg) F axis to obtain mL (mg) F in sample,  $V_e$ .

(b) *Semi-antilog paper*.—Plot  $E$  directly for both blank and sample, descending 5 mv for each major line crossing vertical axis. At top of vertical axis place most neg.  $E$  reading which still allows extrapolation of  $V_e$  on left portion of mL (mg) side of horizontal axis. Obtain  $V_e$  and  $V_e'$  by extrapolation to left side of 0 mL (mg) F.

$$\% F = (V_e - V_e') \times (B \times 100) / [W \times C \times 1000 \text{ (mg/g)}],$$

where  $B$  = vol. of diln,  $W$  = mL or g sample, and  $C$  = aliquot (50 mL max.) buffered to 100 mL.

## PREPARATIONS CONTAINING METHANOL

### Methanol (3)—Official Final Action

(Applicable in presence of acetone, BuOAc, EtOH, isopropanol, hexane, MeEt ketone,  $\text{CH}_2\text{Cl}_2$ , Me Cellosolve, paraffin, toluene, and  $\text{H}_2\text{O}$ . This includes many paint removers, fuels, liq. sanders, antifreezes, and paint products.)

#### 5.008

#### Apparatus and Reagents

(a) *Gas chromatograph*.—With flame ionization detector and oven capable of temp. changes  $\geq 5^\circ/\text{min}$  near  $160^\circ$  or preferably temp. programmer. *Column*.—1.8 m (6')  $\times$  4 mm id packed with 120–150 mesh Porapak R (Waters Associates, Inc., PO Box 246, Milford, MA 01757); condition 2 hr at  $235^\circ$ . *Conditions*: Temps ( $^\circ$ ): injection ca 200, column ca 160, detector ca 210; N flow ca 25 mL/min; set electrometer so that 8  $\mu\text{L}$  std soln provides at least half scale peak. Adjust column temp. and N flow so that MeOH retention time is ca 5–7 min.

(b) *Methanol std soln*.—0.4% (v/v). Dil. 4.00 mL MeOH to 100 mL with dioxane; dil. 10.0 mL of this soln to 100 mL with dioxane. Rinse pipet into flask before dilg to vol. with dioxane. Prep. fresh daily.

#### 5.009

#### Preparation of Sample

(a) *For asphalt-base tar compounds and viscous adhesives*.—Refrigerate unopened sample container  $\geq 3$  hr (longer for larger containers) at  $1\text{--}10^\circ$ , open container, and mix well; close container and refrigerate 30 min more. Transfer 1.5–3 g sample to tared, 250 mL, wide-mouth g-s erlenmeyer (tared with stopper in place). Let sample reach room temp. in stoppered erlenmeyer and weigh. Refrigerate 30 min and quickly add 100.0 mL dioxane. Stopper and shake mech. 1 hr. Refrigerate 30 min and filter thru rapid paper (S&S sharkskin, or equiv.). Filter as quickly as possible, covering funnel with watch glass and placing funnel against neck of narrow-mouth g-s receiver. Proceed as in 5.010, dilg with dioxane, if necessary.

(b) *For other less viscous products*.—Prep. soln with pipets and vol. flasks to contain ca 0.4% (v/v) MeOH, dilg with dioxane. Avoid excessive shaking of semiviscous products and do not fill pipet above mark. (Use safety pipet filler to draw liq. to mark and hold until transfer.) Wash pipet with dioxane and add washings to soln.

If MeOH concn is unknown, prep. 2% soln. Prep. addnl dilns as needed.

#### 5.010

#### Determination

Inject portion std soln with 10  $\mu\text{L}$  syringe. Note vol. At  $R_{\text{MA}}$  (retention time relative to MeOH) ca 0.5, inject portion sample soln. Note vol. At  $R_{\text{MA}}$  ca 2 (from second injection), repeat injection of std soln. At  $R_{\text{MA}}$  ca 0.5 (from third injection), repeat injection of sample soln. After MeOH from fourth injection elutes, increase column temp. to  $235^\circ$  as rapidly as possible for time ca  $4 \times R_{\text{MA}}$  until all dioxane ( $R_{\text{MA}}$  ca 5) is removed from column. Cool column to  $160^\circ$  and repeat sequence for subsequent sample. Modify injection time if necessary to sep. MeOH from other peaks. (Note: Injection sequence is used only to save time; it need not be used if desired.)

#### 5.011

#### Calculation

Det. retention areas for each MeOH peak by multiplying peak ht by retention distance. Average retention areas for sample ( $RA$ ) and for std ( $RA'$ ). Presence of solv. in column changes retention times, requiring use of retention areas in calcn.

$$\% \text{ MeOH (w/v) in sample soln} = F \times (RA/RA') \times (V'/V) \times C \times 0.79,$$

where  $F$  = diln factor,  $C$  = % (v/v) std soln,  $V$  and  $V'$  = vol. sample and std soln injected, resp., and 0.79 = density of MeOH.

## Volatile Denaturants in Alcoholic Products (4) Official First Action

#### 5.012

#### Apparatus and Reagents

(a) *Gas chromatograph and integrator*.—See 19.001(a) and (b).

(b) *Std solns*.—6% (v/v). Dil. 6.00 mL of each denaturant of interest to 100 mL with anhyd. alcohol in sep. vol. flasks. Approx. slopes and retention times relative to  $n$ -PrOH are given in Table 5.01.

Table 5.01 Approximate Slopes and Retention Times Relative to  $n$ -Propyl Alcohol (RT) for Denaturants

Compound	Slope	RT
Acetone	0.207	0.694
Benzene	0.464	2.309
$n$ -Butyl alcohol	0.269	2.283
$sec$ -Butyl alcohol	0.246	1.621
Chloroform	0.058	1.543
Ethyl acetate	0.192	1.640
Ethylene glycol monoethyl ether	0.187	3.868
Ethylene glycol monomethyl ether	0.151	2.071
Isopropanol	0.210	0.727
Methanol	0.130	0.266
Methyl isobutyl ketone	0.275	5.436
Toluene	0.454	5.302

#### 5.013

#### Determination

Pipet 25 mL of each expected denaturant std soln into sep. flasks and add 1.00 mL  $n$ -PrOH as internal std. Proceed as in 19.002, starting with "Cap immediately . . .", except inject 0.3  $\mu\text{L}$  portions. Det. peak areas and calc. slope for each compd as:

$$S_x = (PA_x/PA_i)/6.00,$$

where  $PA_x$  and  $PA_i$  = peak areas of compd X in std soln and of  $n$ -PrOH internal std, resp., and 6.00 = % compd X in std soln. Slopes and retention times should approximate those of Table 5.01.

$$\% \text{ Compd X in sample} = (PA/PA_i) = (1/S_x),$$

where  $PA$  = peak area of compd X in sample.

## PREPARATIONS CONTAINING PHENOL

## Phenol

**Method I (5)—Official Final Action**

(Applicable to com. cresols, saponified cresol solns, coal tar dips, and disinfectants, and to kerosene solns of phenols in absence of salicylates or  $\beta$ -naphthol)

5.014

**Reagents**

(Caution: See 51.026 and 51.065.)

(a) *Dilute nitric acid*.—Aerate  $\text{HNO}_3$  until colorless and dil. 1 vol. with 4 vols  $\text{H}_2\text{O}$ .

(b) *Millon reagent*.—To 2 mL Hg in 200 mL erlenmeyer under hood, add 20 mL  $\text{HNO}_3$ . After first violent reaction, shake as needed to disperse Hg and maintain action. After ca 10 min, when action practically ceases even in presence of undissolved Hg, add 35 mL  $\text{H}_2\text{O}$ , and if basic salt seps, add enough dil.  $\text{HNO}_3$  to dissolve it. Add 10% NaOH soln dropwise with thoro mixing until curdy ppt that forms after adding each drop no longer redissolves but disperses as permanent turbidity. Add 5 mL dil.  $\text{HNO}_3$  and mix well. Prep. fresh daily. Millon reagent is dangerously poisonous and should not be transferred with ordinary pipet and mouth suction unless protective trap is used.

(c) *Phenol std soln*.—Dissolve weighed amt pure phenol (congealing point  $\geq 40^\circ$ ) in enough  $\text{H}_2\text{O}$  to make  $\geq 1\%$  soln. On day it is to be used, dil. to make 0.025% aq. soln (final std).

(d) *Formaldehyde soln*.—Dil. 2 mL 37% HCHO soln to 100 mL with  $\text{H}_2\text{O}$ .

(e) *Methyl orange indicator*.—0.5% aq. soln.

5.015

**Apparatus**

(a) *Nessler cylinders*.—50 mL tall-form, matched.

(b) *Test tubes*.—Approx. 180  $\times$  20 mm, with rubber stoppers, marked at 25 mL.

(c) *Water bath for heating test tubes*.—Beaker contg disk of wire gauze raised ca 2.5 cm from bottom may be used.

5.016

**Preparation of Sample**

(a) *Commercial cresol*.—Weigh by difference ca 2.5 g sample into 250 mL vol. flask, dissolve in 10 mL 10% NaOH soln, and dil. to vol. with  $\text{H}_2\text{O}$ .

(b) *Saponified cresol solns, coal tar dips and disinfectants, kerosene solns of phenols, etc.*—Weigh by difference ca 5 g sample (or use 5 mL and calc. wt from density) into 250 mL vol. flask and dil. to vol. with  $\text{H}_2\text{O}$ . With products consisting largely of kerosene, bring  $\text{H}_2\text{O}$  level to mark and take aliquots from aq. portion only.

5.017

**Determination**

Transfer 5 mL aliquot prep'd soln to 200 mL vol. flask and promptly dil. to ca 50 mL. Add 1 drop Me orange, (e), and then dil.  $\text{HNO}_3$  until soln is practically neut. Dil. to vol. and shake well.

Place 5 mL dild soln in each of 2 marked test tubes; in each of 2 addnl test tubes place 5 mL std phenol soln. Flow 5 mL Millon reagent down side of each tube, mix, and place tubes in boiling  $\text{H}_2\text{O}$  bath; continue boiling exactly 30 min, cool immediately and thoroly by immersion in bath of cold  $\text{H}_2\text{O}$   $\geq 10$  min, and add 5 mL dil.  $\text{HNO}_3$  to each tube.

Mix well and add 3 mL HCHO soln to one of each pair of tubes. Dil. all tubes to 25 mL mark with  $\text{H}_2\text{O}$ , stopper, shake well, and let stand overnight. (Tubes contg HCHO fade to yellow; others show orange or red color.)

Pipet 20 mL from each of the 2 phenol tubes to 100 mL vol. flasks; add 5 mL dil.  $\text{HNO}_3$  to each, dil. to vol., and mix. (Red flask contains "phenol std," yellow flask "phenol blank.") Transfer these solns to burets. Pipet 10 mL of each sample soln into Nessler tubes. (The orange or red constitutes the "unknown" and the yellow the "sample blank." Mark each Nessler tube distinctly to avoid confusion.) To "sample blank" tube add measured amt of "phenol std" and add same vol. "phenol blank" to "unknown." Agitate thoroly (aided by insertion of rubber stoppers, if necessary), and compare colors. When tubes are brought to match, each mL phenol std used = 1% phenol if sample weighing exactly 5 g was used, or 2% if exactly 2.5 g was used.

*Note*.—Take following precautions: Pair of phenol tubes provides enough final solns to assay several unknowns, but all the latter must have accompanied phenol solns thruout entire process with identical reagents and treatment. If end point is inadvertently overrun it is possible to work back to it, but since mistakes may be made in this operation it is better to repeat comparison on fresh portions from original tubes. Too much delay in matching tubes must be avoided after titrn is started, otherwise excess HCHO present in blanks may have time after mixing to affect intensity of red color.

**5.018 Method II (6)—Official Final Action**

(Applicable to detn of phenol in presence of salicylates)

Weigh by difference 10 g sample into separator (or use 10 mL and calc. wt from density of sample). Add 50 mL kerosene and ext with three 100 mL portions  $\text{H}_2\text{O}$ . Filter aq. exts thru wet filter into 500 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and proceed as in 5.017.

When tubes are brought to match, each mL phenol std used = 1% phenol if sample weighing exactly 10 g was used.

## SODA LYE

**Carbonate and Hydroxide (7)—Official Final Action**

5.019

**Determination**

Weigh ca 10 g sample from weighing bottle, dissolve in  $\text{CO}_2$ -free  $\text{H}_2\text{O}$ , and dil. to definite vol. Titr. aliquot with 0.5N HCl, 50.011—50.012, using Me orange, 5.014(e), and note total alky found. Transfer equal aliquot to vol. flask and add enough 10%  $\text{BaCl}_2$  soln to ppt all carbonate, avoiding any unnecessary excess. Dil. to vol. with  $\text{CO}_2$ -free  $\text{H}_2\text{O}$ , stopper, shake, and let stand. When liq. clears, pipet off one-half and titr. with the 0.5N HCl, using phthln; mL 0.5N acid required for this titrn  $\times 2$  = mL 0.5N acid equiv. to NaOH present in original aliquot. Difference between this figure and mL 0.5N HCl required for total alky = mL 0.5N acid equiv. to  $\text{Na}_2\text{CO}_3$  present in aliquot. Calc. %  $\text{Na}_2\text{CO}_3$  and NaOH.

## EARTHENWARE

5.020 Cadmium and Lead

See 25.031—25.037.

## 6. Pesticide Formulations

(Pesticide ref. stds may be available from the following: Alltech Associates, 202 Campus Dr, Arlington Hts, IL 60004; Analabs, Inc.; Applied Science Laboratories; Chem Service Inc., Westchester, PA 19380; ICN-K&K Laboratories, Inc.; RFR Corp., 1 Main St, Hope, RI 02831; and Supelco.)

### GENERAL METHODS

#### 6.001 Sampling—Procedure

(Caution: See 51.041.)

Examine shipping cases closely for code numbers, different labels, and other pertinent information. Give special attention to products subject to deterioration.

**Caution:** Use care in sampling and transporting toxic materials to avoid personal injury and contamination of transportation facilities in case of breakage. When dealing with rodenticides and weed-killers, avoid mutual contamination with other products during transportation.

Mark each sample container according to laboratory requirements.

(a) *Small package retail units.*—Take one unopened unit (1 lb if dry, 1 pt if liq.), except take min. of 2 units of small baits in cake form. Size of sample is governed by composition of material and anal. methods.

(b) *Large package dry products (25 lb or more).*—Sample unopened containers, using trier long enough to reach bottom of container by inserting into container at one edge or corner and probing diagonally toward opposite edge or corner. Take cores by code or batch number. Analyze cores from same code or batch number as composite or individually. Clean trier thoroughly after sampling each batch.

Store samples in air-tight glass, metal, plastic, or cardboard containers.

(c) *Large package liquid products (5 gallons or more).*—Use glass, plastic tubing, or stainless steel trier with plunger, or rubber tubing for certain materials. Store samples in glass or containers of other noncorrosive material with screw top caps lined with Teflon or other inert material. Plastic containers may be used only for carefully selected products.

#### 6.002 Sampling of Pressurized Containers (7) Official First Action

**Delivery assembly.**—Construct U-shaped stainless steel assembly from  $\frac{1}{8}$ " od tubing, with 1 arm 70 mm long with front and back ferrules (Swagelok No. SS-204-1 and SS-203-1, Crawford Fitting Co., 29500 Solon Rd, Solon, OH 44139) permanently swaged 3 mm from end, and other arm 135 mm longer (205 mm total length) sepd by 75 mm bend. Remove spray head from can. For male-type outlet, attach assembly from above ferrule to outlet with short piece of Tygon tubing. For female-type outlet, insert ferrule directly into outlet. Sample is released from can by carefully applying firm hand pressure to shoulder of assembly. See Fig. 6:01.

**Sampling.**—Remove cover and spray head from can. Place can and delivery assembly in 800 mL beaker and weigh ( $W_0$ ). Shake can vigorously 5 min. Immediately after shaking attach delivery assembly to spray outlet. Immerse long end into 250 mL separator contg 100 mL  $\text{CHCl}_3$ . Press shoulder to deliver ca 9 g sample (ca 10 sec) into  $\text{CHCl}_3$ . Return can and delivery assembly to beaker and weigh. Shake can vigorously 3 min and repeat delivery of sample until total of 10–15 g is obtained in

$\text{CHCl}_3$ . Reweigh can and delivery assembly in beaker ( $W$ ). Calc. sample wt as ( $W_0 - W$ ).

#### 6.003 Preparation of Sample—Official Final Action

Thoroughly mix all samples before analysis. Det.  $\text{H}_2\text{O}$ -sol. As on samples as received, without further pulverization or drying. In case of lye, NaCN, or KCN, weigh large amts in weighing bottles and analyze aliquots of their aq. solns.

#### 6.004 Moisture—Official Final Action

(Applicable to Paris green, powd Pb arsenate, Ca arsenate, Mg arsenate, Zn arsenite, powd Bordeaux mixt., and Bordeaux mixt. with arsenicals)

Dry 2 g to const wt at  $105\text{--}110^\circ$  and report loss in wt as moisture.

### ARSENIC

#### Total Arsenic—Official Final Action

##### Hydrazine Sulfate Distillation Method (2)

(Nitrates do not interfere. Applicable to detn of total As in Paris green, Pb arsenate, Ca arsenate, Zn arsenite, Mg arsenate, and Bordeaux mixt. with arsenicals)

#### 6.005

#### Reagents

(a) *Arsenious oxide std soln.*—0.1 or 0.05N. See 50.005–50.006.

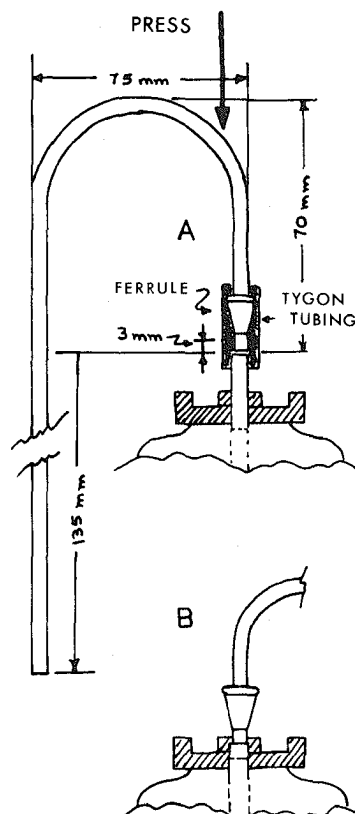

FIG. 6:01—Delivery assembly for sampling pressurized containers

(b) *Iodine std soln.*—0.1 or 0.05*N*. See 50.018–50.019.

(c) *Bromate std soln.*—0.1 or 0.05*N*. Dissolve ca 2.8 or 1.4 g  $\text{KBrO}_3$  in boiled  $\text{H}_2\text{O}$  and dil. to 1 L. Stdze as follows: Pipet 25 mL aliquots  $\text{As}_2\text{O}_3$  soln, (a), into 500 mL erlenmeyers. Add 15 mL  $\text{HCl}$ , dil. to 100 mL, heat to  $90^\circ$ , and titr. with the  $\text{KBrO}_3$  soln, using 10 drops Me orange, (g). Do not add indicator until near end of titrn, and agitate soln continuously to avoid local excess of  $\text{KBrO}_3$  soln. Add  $\text{KBrO}_3$  soln very slowly near end point; at end point soln changes from red to colorless.

(d) *Hydrazine sulfate-sodium bromide soln.*—Dissolve 20 g  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{SO}_4$  and 20 g  $\text{NaBr}$  in 1 L  $\text{HCl}$  (1+4).

(e) *Sodium hydroxide soln.*—Dissolve 400 g  $\text{NaOH}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(f) *Starch indicator.*—Mix ca 2 g finely powd. potato starch with cold  $\text{H}_2\text{O}$  to thin paste; add ca 200 mL boiling  $\text{H}_2\text{O}$ , stirring constantly, and immediately discontinue heating. Add ca 1 mL  $\text{Hg}$ , shake, and let soln stand over the  $\text{Hg}$ .

(g) *Methyl orange indicator.*—0.05%. Dissolve 0.5 g Me orange in  $\text{H}_2\text{O}$  and dil. to 1 L.

#### 6.006

#### Apparatus

See Fig. 6.02. Set 500 mL distn flask on metal gauze that fits over circular hole in heavy sheet of asbestos board, which in turn extends out far enough to protect sides of flask from direct flame of burner. First receiving flask holds 500 mL and contains 40 mL  $\text{H}_2\text{O}$ ; second holds 500 mL and contains 100 mL  $\text{H}_2\text{O}$ . Vol. in first flask should be  $\leq 40$  mL, otherwise compd of As may sep. that is difficult to dissolve without danger of loss of  $\text{AsCl}_3$ . Keep both flasks cool by placing in pan of circulating  $\text{H}_2\text{O}$ , or contg  $\text{H}_2\text{O}$  and ice.

#### 6.007

#### Determination

(Caution: See 51.041 and 51.078.)

Weigh sample contg  $\leq 0.4$  g As and transfer to distg flask. Add 50 mL  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{SO}_4\text{-NaBr}$  soln, close flask with stopper that carries funnel tube, and connect side tube with condenser. Boil 2–3 min, add 100 mL  $\text{HCl}$  from dropping funnel, and distil until vol. in distg flask is reduced to ca 40 mL; add 50 mL more  $\text{HCl}$  and continue distn until vol. is again reduced to ca 40 mL. Wash down condenser, transfer contents of receiving flasks to 1 L vol. flask, dil. to vol., mix thoroly, and proceed as in (a) or (b):

(a) Pipet 200 mL aliquot into erlenmeyer and nearly neutze with  $\text{NaOH}$  soln, using few drops phthln, and keeping soln well cooled. If neut. point is passed, add  $\text{HCl}$  until again slightly acid. Neutze with  $\text{NaHCO}_3$ , add 4–5 g excess, and add std I soln from buret, shaking flask continuously until yellow color disappears slowly from soln. Add 5 mL starch indicator and keep adding std I soln dropwise to permanent blue.

(b) Pipet 200 mL aliquot into erlenmeyer and titr. with  $\text{KBrO}_3$  soln, (c), beginning "... heat to  $90^\circ$  ..."

Calc. % As. Report as  $\text{As}_2\text{O}_3$  or  $\text{As}_2\text{O}_5$ , according to whether As is present in trivalent or pentavalent form. If condition of arsenic is unknown, report as As.

#### Iodimetric Method (3)

(Applicable in presence of sulfides, sulfites, thiosulfates, and large amts of S or org. matter)

#### 6.008

#### Reagent

*Sodium thiosulfate soln.*—Dissolve 13 g crystd  $\text{Na}_2\text{S}_2\text{O}_3\cdot 5\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

See 6.005 for other reagents and solns and 6.006 for app.

#### 6.009

#### Determination

(Caution: See 51.041 and 51.078.)

Weigh sample contg  $\leq 0.4$  g As and transfer to distg flask. Add 50 mL  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{SO}_4\text{-NaBr}$  soln, 6.005(d), and distil as in 6.007. Dil. distillate to vol. in 1 L vol. flask, mix thoroly, and transfer 200 mL aliquot to 400 mL Pyrex beaker or porcelain casserole. Add 10 mL  $\text{HNO}_3$  and 5 mL  $\text{H}_2\text{SO}_4$ , evap. to sirupy consistency on steam bath, and then heat on hot plate to white fumes of  $\text{H}_2\text{SO}_4$ . Cool, and wash into 500 mL erlenmeyer. If vol.  $\text{H}_2\text{SO}_4$  is appreciably lessened by fuming, add enough  $\text{H}_2\text{SO}_4$  to make total vol. ca 5 mL. Dil. to 100–150 mL, add 1.5 g  $\text{KI}$ , and boil until vol. is reduced to ca 40 mL. Cool under running  $\text{H}_2\text{O}$ , dil. to 100–150 mL, and add  $\text{Na}_2\text{S}_2\text{O}_3$  soln, 6.008, dropwise until I color just disappears. Nearly neutze  $\text{H}_2\text{SO}_4$  with  $\text{NaOH}$  soln, 6.005(e), finish neutzn with  $\text{NaHCO}_3$ , add 4–5 g excess, and titr. with std I soln as in 6.007(a). From mL std soln used, calc. % As in sample. Report as  $\text{As}_2\text{O}_3$ ,  $\text{As}_2\text{O}_5$ , or As as in 6.007.

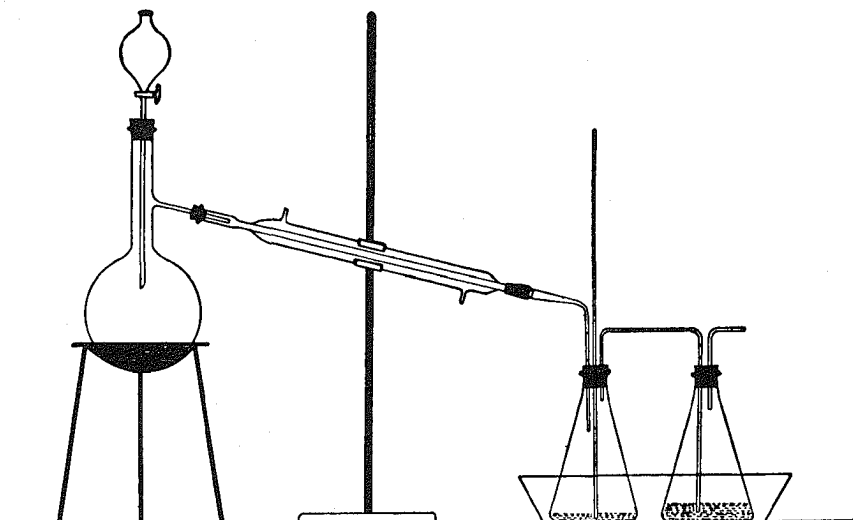

FIG. 6.02—Apparatus for distilling arsenious chloride

**Ion Exchange Method (4)—Official Final Action**

(Applicable to inorg. arsenates and arsenites)

**6.010****Apparatus**

*Ion exchange column.*—Use Allihn filter tube 10 × 2.7 cm od with coarse filter disk. Attach piece of rubber tubing to bottom of filter tube and regulate flow with Hoffman clamp. To tube add aq. slurry of Dowex 50W-X8, 50–100 mesh, using resin bed vol. of 12 mL, and place 500 mL separator above tube.

Regenerate resin bed before each run by first back-washing column few min with H<sub>2</sub>O; then elute with 350 mL 2*N* HCl followed by 200 mL H<sub>2</sub>O at 20 mL/min.

**6.011****Preparation of Sample**

(Caution: See 51.041.)

Weigh 200 mg sample (100 mg if As content is >30%) into 150 mL beaker, add 7 mL HNO<sub>3</sub>, and bring to bp. Add 3 mL 2*N* KBrO<sub>3</sub> and evap. to dryness, avoiding spattering. Backwash and regenerate resin during this evapn. Dissolve cooled residue in 2 mL 6*N* HCl without heat and add 8 mL H<sub>2</sub>O. Filter into separator, and wash filter with three 10 mL portions H<sub>2</sub>O. (If residue dissolves completely in 2 mL 6*N* HCl, omit filtration, and dil. directly to 40 mL.) Pass soln thru resin column at 20 mL/min and collect eluate in 250 mL erlenmeyer. Wash separator and column with 20 and 40 mL portions H<sub>2</sub>O into same erlenmeyer.

**6.012****Determination**

Add 50 mL HCl to eluate to make 4*N*. Add 1 g NaHCO<sub>3</sub>, 0.2 g at time, swirling constantly. Add 1 g KI, stopper, and swirl until all KI dissolves. After 5 min, titr., without starch indicator, with 0.05*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, **50.037–50.038**, to disappearance of I. (Recognition of end point is facilitated by titrg on porcelain stand. In presence of starch, reaction between I and Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> is retarded, so appreciable amt of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> reacts with acid. End point becomes indistinct if >30 mL Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> is used in titrn.) 1 mL 0.05*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 1.873 mg As.

**Water-Soluble Arsenic—Official Final Action**(Applicable to detn of H<sub>2</sub>O-sol. arsenic in Pb arsenate, Ca arsenate, Zn arsenite, Mg arsenate, and Bordeaux mixt. with arsenicals)**6.013****Determination**

(Caution: See 51.041.)

To 2 g original sample if powder, or 4 g if paste, in 1 L Florence flask, add 1 L recently boiled H<sub>2</sub>O that has been cooled to 32°. Stopper flask and place in constant temp. H<sub>2</sub>O bath at 32°. Digest 24 hr, shaking hourly 8 hr during this period. Filter thru dry filter. If filtrate is not clear, refilter thru buchner contg paper and enough Filter-Cel coating to give clear soln. Discard first 50 mL.

Transfer 250–500 mL *clear* filtrate to erlenmeyer, add 3 mL H<sub>2</sub>SO<sub>4</sub>, and evap. to ca 100 mL on hot plate. Add 1 g KI, and continue boiling until vol. is ca 40 mL. Cool, dil. to ca 200 mL, and add Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, **6.008**, dropwise, until I color is exactly removed. (Avoid use of starch indicator at this point.) Neutze with NaHCO<sub>3</sub>, add 4–5 g excess, titr. with std I soln, shaking flask continuously, until yellow disappears slowly, add 5 mL starch indicator, **6.005(f)**, and continue titrn to permanent blue. Correct for amt std I soln necessary to produce same color, using same reagents and vol. From mL std I soln used, calc. % H<sub>2</sub>O-sol. As in sample.

**LEAD (5)—OFFICIAL FINAL ACTION**

(Applicable to such preps as Bordeaux-Pb arsenate, Bordeaux-Zn arsenite, Bordeaux-Paris green, and Bordeaux-Ca arsenate)

(Caution: See 51.026, 51.031, 51.041, 51.059, and 51.078.)

**6.014****Determination**

Weigh 1 g powd sample and transfer to beaker. Add 5 mL *HBr* (ca 1.38 sp gr) and 15 mL HCl, and evap. to dryness to remove As. Repeat treatment; add 20 mL HCl, and again evap. to dryness. Add 25 mL 2*N* HCl to residue, heat to bp, filter immediately to remove SiO<sub>2</sub>, and wash with boiling H<sub>2</sub>O to vol. of 125 mL. See that all PbCl<sub>2</sub> is in soln before filtering; if it will not dissolve completely in 25 mL 2*N* acid, add 25 mL more and dil. filtrate to 250 mL. Pass in H<sub>2</sub>S until pptn is complete. Filter, and wash ppt thoroly with 0.5*N* HCl satd with H<sub>2</sub>S. Save filtrate and washings for Zn detn.

Transfer paper with sulfides of Pb and Cu to 400 mL Pyrex beaker and completely oxidize all org. matter by heating on steam bath with 4 mL H<sub>2</sub>SO<sub>4</sub> and ca 20 mL *fuming HNO<sub>3</sub>* in covered beaker. Evap. on steam bath, and then completely remove HNO<sub>3</sub> by heating on hot plate to copious white fumes of H<sub>2</sub>SO<sub>4</sub>. Cool, add 2–3 mL H<sub>2</sub>O, and again heat to fuming. Cool, add 50 mL H<sub>2</sub>O and 100 mL alcohol, and let stand several hr (preferably overnight). Filter thru gooch, previously washed with H<sub>2</sub>O, then with *acidified alcohol* (100 parts H<sub>2</sub>O, 200 parts alcohol, and 3 parts H<sub>2</sub>SO<sub>4</sub>), and finally with alcohol, and dried at 200°. Wash ppt of PbSO<sub>4</sub> in crucible ca 10 times with acidified alcohol, and then with alcohol, to remove H<sub>2</sub>SO<sub>4</sub>. Retain filtrate and washings for Cu detn, if desired.

Dry at 200° to const wt, keeping crucible covered to prevent loss from spattering. From wt PbSO<sub>4</sub>, calc. % Pb in sample, using factor 0.6832.

**COPPER (5)—OFFICIAL FINAL ACTION**

(Applicable to such preps as Bordeaux-Pb arsenate, Bordeaux-Zn arsenite, Bordeaux-Paris green, and Bordeaux-Ca arsenate)

**6.015 Electrolytic Method**

Evap. filtrate and washings from PbSO<sub>4</sub> pptn, **6.014**, to fuming; add few mL *fuming HNO<sub>3</sub>* to destroy org. matter, and continue evapn to ca 3 mL. Take up with ca 150 mL H<sub>2</sub>O, add 5 mL HNO<sub>3</sub>, and filter if necessary. Wash into 250 mL beaker, adjust vol. to 200 mL, and electrolyze, using rotating anode and weighed gauze cathode with current of 2–3 amp. After all Cu has apparently deposited (ca 30 min), add 15–20 mL H<sub>2</sub>O to electrolyte and continue electrolysis few min. If no further deposition occurs on newly exposed surface of electrode, wash with H<sub>2</sub>O without breaking current either by siphoning or quickly replacing beaker with electrolyte successively with 2 beakers of H<sub>2</sub>O. Interrupt current, rinse cathode with alcohol, dry few moments in oven, and weigh. Calc. % Cu in sample.

**6.016 Volumetric Thiosulfate Method**

Proceed as in **6.015** to point at which filtrate and washings from PbSO<sub>4</sub> pptn are treated with *fuming HNO<sub>3</sub>* and evapd to vol. of ca 3 mL. Take up in ca 50 mL H<sub>2</sub>O, add NH<sub>4</sub>OH in excess, and boil to expel excess NH<sub>3</sub>, as shown by color change in liq. and partial pptn. Add 3–4 mL HOAc (4+1), boil 1–2 min, cool, add 10 mL 30% KI soln, and titr. with std Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, **31.040**, until brown color becomes faint. Add starch indicator, **6.005(f)**, and continue titrn cautiously until blue color due to free I entirely disappears. From mL std Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln used, calc. % Cu in sample.

**ZINC (6)—OFFICIAL FINAL ACTION**

(Applicable to such preps as Bordeaux-Pb arsenate, Zn arsenite, Bordeaux-Zn arsenite, Bordeaux-Paris green, and Bordeaux-Ca arsenate)

**6.017****Reagent**

*Mercury-thiocyanate soln.*—(Caution: See 51.079.) Dissolve 27 g HgCl<sub>2</sub> and 30 g NH<sub>4</sub>SCN in H<sub>2</sub>O and dil. to 1 L.

**6.018****Determination**

Conc. filtrate and washings from sulfide pptn, 6.014, by gentle boiling to ca 50 mL; then evap. on steam bath to dryness. Dissolve residue in 100 mL H<sub>2</sub>O contg 5 mL HCl, and add 35–40 mL Hg-thiocyanate soln with vigorous stirring. Let stand ≥1 hr with occasional stirring. Filter thru weighed gooch, wash with H<sub>2</sub>O contg 20 mL Hg-thiocyanate soln/L, and dry to const wt at 105°. Calc. to % Zn, using factor 0.1312.

*Note:* Some Fe is usually present and during Zn detn should be in ferrous condition. In pptg sulfides pass H<sub>2</sub>S into soln long enough to reduce Fe as well as to ppt Cu and Pb. ZnHg(SCN)<sub>4</sub> ppt normally is white, and occluded Fe(SCN)<sub>3</sub> should not give more than faint pink color.

**FLUORINE****Total Fluorine—Official Final Action****Lead Chlorofluoride Method (7)****6.019****Reagents**

(a) *Fusion mixture.*—Mix 30 g anhyd. Na<sub>2</sub>CO<sub>3</sub> with 40 g anhyd. K<sub>2</sub>CO<sub>3</sub>.

(b) *Lead chlorofluoride wash soln.*—Dissolve 10 g Pb(NO<sub>3</sub>)<sub>2</sub> in 200 mL H<sub>2</sub>O, dissolve 1 g NaF in 100 mL H<sub>2</sub>O and add 2 mL HCl, and mix these 2 solns. Let ppt settle and decant. Wash ppt 4 or 5 times with 200 mL H<sub>2</sub>O by decanting; then add ca 1 L cold H<sub>2</sub>O to ppt and let stand ≥1 hr, with occasional stirring. Filter and use clear filtrate. (Prep. more wash soln as needed by adding more H<sub>2</sub>O to ppt of PbClF and stirring.)

(c) *Silver nitrate std soln.*—0.1 or 0.2N. Stdze as in 50.031.

(d) *Potassium or ammonium thiocyanate std soln.*—0.1N. Stdze against std AgNO<sub>3</sub> soln under same conditions as in detn.

(e) *Ferric indicator.*—To cold satd Cl-free FeNH<sub>4</sub>(SO<sub>4</sub>)<sub>2</sub>·12H<sub>2</sub>O soln add enough colorless HNO<sub>3</sub> to bleach brown color.

(f) *Bromophenol blue indicator.*—Grind 0.1 g powder with 1.5 mL 0.1N NaOH and dil. to 25 mL.

**6.020****Determination**

(a) *Samples difficult to decompose such as cryolite, and others that contain aluminum or appreciable amounts of siliceous material.*—Mix 0.5 g sample (or less if necessary to contain 0.01–0.10 g F) with 5 g fusion mixt. and 0.2–0.3 g powd. SiO<sub>2</sub> in Pt dish, cover with 1 g fusion mixt., and heat to fusion over Bunsen burner. (Use of blast lamp is unnecessary since it is preferable not to heat much beyond melting temp. If much Al is present, uniform, clear, liq. melt cannot be obtained; particles of white solid will sep. in melt. Cooled melt should be colorless, or at least should not have more than gray color.)

Leach cooled melt with hot H<sub>2</sub>O and when disintegration is complete, filter into 400 mL beaker. Return insol. residue to Pt dish with jet of H<sub>2</sub>O, add 1 g Na<sub>2</sub>CO<sub>3</sub>, dil. to 30–50 mL, and boil few min, disintegrating any lumps with flat-end rod. Filter thru same paper, wash thoroly with hot H<sub>2</sub>O, and adjust vol. of filtrate and washings to ca 200 mL. Add 1 g ZnO dissolved in 20 mL HNO<sub>3</sub> (1+9), boil 2 min, stirring constantly, filter, and wash thoroly with hot H<sub>2</sub>O. During this washing return gelatinous

mass to beaker 3 times and thoroly disintegrate in wash soln because proper washing of this ppt on filter is difficult. (Mass can easily be returned to beaker by rotating funnel above beaker while cutting ppt loose from paper with jet of wash soln.)

Add 2 drops bromophenol blue to filtrate, and with cover glass almost entirely over beaker, add HNO<sub>3</sub> (1+4) until color just changes to yellow. Make soln slightly alk. with 10% NaOH soln, and with cover glass on beaker, boil gently to expel CO<sub>2</sub>. Remove from burner; add the HNO<sub>3</sub> until color just changes to yellow and then 10% NaOH until color just changes to blue; then add 3 mL 10% NaCl soln. (Vol. of soln at this point should be ca 250 mL.)

Add 2 mL HCl (1+1) and 5 g Pb(NO<sub>3</sub>)<sub>2</sub> and heat on steam bath. As soon as Pb(NO<sub>3</sub>)<sub>2</sub> is in soln, add 5 g NaOAc, stir vigorously, and digest on steam bath 30 min with occasional stirring. Let stand overnight, filter, and wash ppt, beaker, and paper once with cold H<sub>2</sub>O, then 4 or 5 times with PbClF wash soln, and then once more with cold H<sub>2</sub>O.

Transfer ppt and paper to beaker in which pptn was made, stir paper to pulp, add 100 mL HNO<sub>3</sub> (5+95), and heat on steam bath until ppt dissolves. (5 min is ample to dissolve ppt. If sample contains appreciable amt of sulfates, ppt will contain PbSO<sub>4</sub>, which will not dissolve. In such case heat 5–10 min with stirring and consider PbClF to be dissolved.) Add slight excess 0.1N or 0.2N AgNO<sub>3</sub>, digest on steam bath 30 min, and cool to room temp., protecting from light; filter, wash with cold H<sub>2</sub>O, and det. AgNO<sub>3</sub> in filtrate by titrn with std thiocyanate soln, using 10 mL ferric indicator. Subtract amt of AgNO<sub>3</sub> found in filtrate from that originally added. Difference is amt required to combine with Cl in the PbClF; from this difference calc. % F in sample. 1 mL 0.1N AgNO<sub>3</sub> = 0.00190 g F.

(b) *Water-soluble fluorides in presence of organic matter.*—In presence of ≤50% org. matter such as flour, pyrethrum, tobacco powder, and derris or cubé powders, which readily decompose without addn of powd SiO<sub>2</sub> and contain little or no sulfates, Al, or siliceous compds, mix 0.5 g sample (or less if necessary to contain 0.01–0.1 g F) with 5 g fusion mixt., cover with 1 g fusion mixt., and heat to fusion over Bunsen burner. Leach cooled melt with hot H<sub>2</sub>O, and when disintegration is complete, filter into 600 mL beaker. Wash thoroly with hot H<sub>2</sub>O and proceed as in (a), third par.

In presence of >50% org. matter or org. matter that is impractical to free without preliminary ashing, such as apple peel and pulp, transfer enough sample to Pt crucible to be representative of mixt. and to contain 0.01–0.1 g F. Add 15 mL H<sub>2</sub>O and enough F-free CaO (0.3–0.4 g) to make mixt. distinctly alk. to phthln, mix with glass rod, and evap. to dryness on steam bath and in oven at 105°. Ignite at low heat, preferably in furnace (≤600°), until org. matter is thoroly charred. Pulverize, with glass rod, any lumps present in charred ash, mix with 5 g of the fusion mixt., and proceed as in (a), first par., beginning "... cover with 1 g fusion mixt., ..."

(c) *Water-soluble samples in absence of organic matter and appreciable quantities of sulfates or aluminum salts.*—In absence of org. matter or other interfering substances, fusion may be omitted and detn made on aliquot of aq. soln contg 0.01–0.1 g F, as in (a), third par.

In presence of Al, as in samples contg Na<sub>2</sub>SiF<sub>6</sub> and KAl(SO<sub>4</sub>)<sub>2</sub>·12H<sub>2</sub>O, transfer sample to 400 mL beaker, dissolve in 150 mL hot H<sub>2</sub>O, add 6 g fusion mixt., and boil. Add 1 g ZnO dissolved in 20 mL HNO<sub>3</sub> (1+9), boil 2 min with const stirring, filter into 500 mL vol. flask, and wash thoroly with hot H<sub>2</sub>O. Cool to room temp. and dil. to vol. Transfer 200 mL aliquot contg 0.01–0.10 g F to 600 mL beaker and proceed as in (a), third par.

(d) *Sodium and magnesium fluosilicates, or samples containing more than 5% sulfates in absence of aluminum and*

*boron, with or without moderate amounts of organic matter.*—With large amts of  $\text{Na}_2\text{SiF}_6$  and some other more volatile fluosilicates, e.g.,  $\text{MgSiF}_6$ , where there is possibility of some F being evolved as  $\text{SiF}_4$  before fusion is effected, or in samples contg appreciable amts of sulfates, distil F as in 6.024, and det. F in distillate as follows: Add several drops bromophenol blue, make alk. with NaOH, and adjust vol. to ca 250 mL by gently boiling down vol. from 400 to 250 mL. Proceed as in (a), third par., beginning "Remove from burner; . . ."

*Notes:* These methods give accurate results for 0.01–0.10 g F. Below 0.01 g, results tend to be slightly low, and above 0.10 g, slightly high. Convenient sample to fuse is one contg 0.07–0.08 g F; too large sample may result in incomplete fusion. Large amts of B compds and alkali salts retard or prevent complete pptn of  $\text{PbClF}$ . B has greater effect when amt of F is large than when it is small. In methods described B has little effect, and it may be disregarded in analysis of insecticides if amt of F to be pptd is  $\leq 0.03$  g. With some preps contg  $\text{Na}_2\text{B}_4\text{O}_7$  or  $\text{H}_3\text{BO}_3$ , where it is difficult to obtain representative mixt. when extremely small sample (0.1 g) is used for analysis, take larger sample and ppt  $\text{PbClF}$  from aliquot of fusion soln. Amt of alkali carbonates specified in fusion and in washing of insol. residue is not large enough to cause low results. If sample contains S, remove it with  $\text{CS}_2$  and det. F on air-dried residue, allowing in calcs for % S removed. (Caution: See 51.039, 51.040, and 51.048.)

#### Modified Travers Method (8)

(Applicable in absence of B, Al, and large amts of pyrethrum powder)

#### 6.021

#### Reagents

(a) *Alcoholic potassium chloride soln.*—Dissolve 60 g KCl in 400 mL  $\text{H}_2\text{O}$ , add 400 mL alcohol, and test with phthln; if soln is not neut., adjust to exact neutrality with NaOH or HCl soln.

(b) *Sodium hydroxide std soln.*—0.2N. Prep. and stdze as in 50.032–50.035.

#### 6.022

#### Determination

Treat 0.5 g sample in small beaker with 20–25 mL  $\text{H}_2\text{O}$ . Add 0.3 g finely divided *pptd*  $\text{SiO}_2$  and few drops Me orange. Add HCl dropwise until soln assumes apparently permanent pink;

then add 2 mL excess, cover beaker with watch glass, and boil 1 min. Cool to room temp., add 4 g KCl, and stir until KCl dissolves. Add 25 mL alcohol and let stand 1 hr, stirring frequently. Filter thru gooch contg disk of filter paper covered with medium pad of asbestos. Wash ppt with alc. KCl soln until one washing does not destroy color made by 1 drop 0.2N NaOH and phthln (usually 3–4 washings). Transfer crucible and contents to 400 mL beaker, add 100 mL recently boiled  $\text{H}_2\text{O}$  and 1–2 mL phthln, heat, and titr. with std NaOH soln. Finish titrn with the F soln actively boiling. Calc. % F. 1 mL 0.2N NaOH = 0.0057 g F.

#### Distillation Method (9)

(Applicable to  $\text{H}_2\text{O}$ -sol. or  $\text{H}_2\text{O}$ -insol. insecticides in absence of gelatinous  $\text{SiO}_2$ , B, and Al)

#### 6.023

#### Reagents

(a) *Sodium alizarin sulfonate indicator.*—Dissolve 0.1 g Na alizarin sulfonate in 200 mL  $\text{H}_2\text{O}$ .

(b) *Thorium nitrate soln.*—Approx. 0.05N. Stdze in terms of g F/mL by titrg F obtained by distn from std NaF as in 6.024. In stdzg for use with 6.024(b), add 5 mL satd  $\text{KMnO}_4$  soln in addn to other reagents in distn flask.

#### 6.024

#### Determination

(a) *In absence of organic matter.*—Weigh sample contg ca 0.09 g F, and with aid of little  $\text{H}_2\text{O}$  transfer to 250 mL Claisen distn flask contg 12 glass beads. Adjust to ca 30 mL and close flask with 2-hole rubber stopper, thru which pass thermometer and 4 mm glass tube, both of which extend into soln. (The 4 mm glass tube extends ca 5 cm above rubber stopper and by means of rubber tube, E, connects still with 1 L Florence flask contg  $\text{H}_2\text{O}$  for steam generation. Flask is equipped with steam discharge, H, and pressure tube, G. See Fig. 6:03.)

Bring  $\text{H}_2\text{O}$  in steam generating flask to boil with pinchcock, F, in release tube open. Connect distg flask to condenser, and add 25 mL  $\text{H}_2\text{SO}_4$  thru top of 4 mm tube, using pipet or special funnel. With pinchcock, F, open, connect rubber tubing to 4 mm

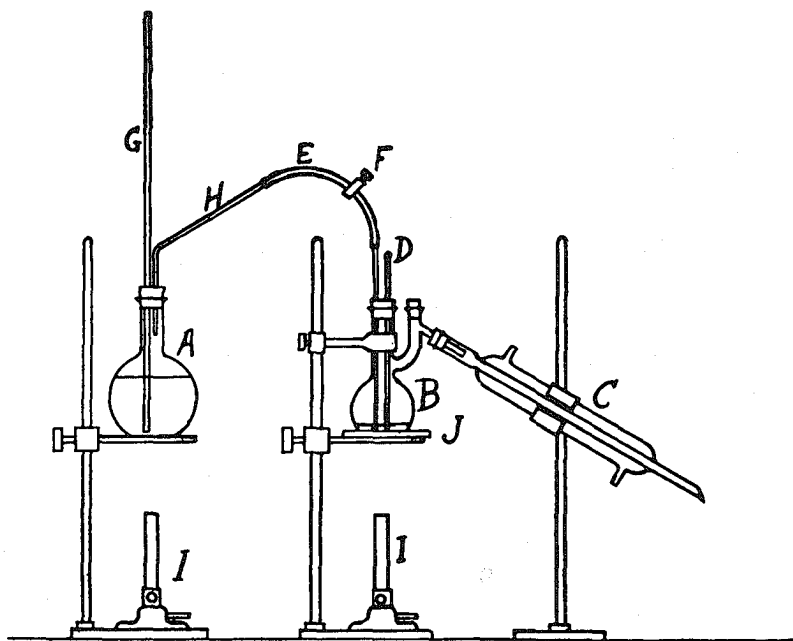

FIG. 6:03—Apparatus for determining fluorine

tube. Light burner under Claisen flask. Regulate flow of steam by adjusting burner flames and pinchcock, *F*, so that vol. of soln is held const and temp. in flask, *B*, is kept at 145–150°. Continue distn until 400 mL distillate collects. Dil. to 500 mL in vol. flask, transfer 50 mL aliquot to tall-form 150 mL beaker, and add 5 drops indicator, **6.023(a)**. Adjust acidity with 1% NaOH soln and HCl (1+249) until pink just disappears. Add 2 mL of the HCl, and titr. with 0.05*N* Th(NO<sub>3</sub>)<sub>4</sub> to permanent pink, using buret graduated in 0.05 mL.

(b) *In presence of organic matter.*—(Caution: See **51.080**.) In presence of moderate amts of org. matter, transfer sample contg ca 0.09 g *F* and contg ≤0.2 g org. matter, with aid of little H<sub>2</sub>O, to 250 mL Claisen distn flask contg 12 glass beads. Add 5 mL satd KMnO<sub>4</sub> soln, adjust to ca 30 mL, and proceed as in (a), beginning "... close flask with 2-hole rubber stopper, ..."

In presence of large amts of org. matter, transfer sample to medium-size Pt dish, add 15 mL H<sub>2</sub>O and enough *F*-free CaO to make mixt. distinctly alk. to phthln, mix with glass rod, and evap. to dryness on steam bath and in oven at 105°. Ignite at low heat, preferably in furnace (≤600°), until org. matter is thoroly charred. Pulverize any lumps present in charred ash with glass rod, transfer to 250 mL Claisen distn flask by brushing, and finally wash out dish with 30 mL H<sub>2</sub>SO<sub>4</sub> (1+9). Except to add 22 mL instead of 25 mL H<sub>2</sub>SO<sub>4</sub>, proceed as in (a), par. 2.

*Note:* If coating of pptd SiO<sub>2</sub> forms on inside of distn flask, remove by treatment with hot concd alkali soln, as it is capable of retaining *F* during distn of some samples and giving it up, at least in part, in later distns.

#### Fluorine Present as Sodium Fluosilicate Official Final Action

(*B*, CaO, and alum absent)

#### 6.025

#### Reagents

*Alcoholic potassium chloride and sodium carbonate soln.*—Dissolve 1.0 g Na<sub>2</sub>CO<sub>3</sub> in 100 mL alc. KCl reagent, **6.021(a)**. For other reagent see **6.021**.

#### 6.026

#### Determination

Weigh 1 g sample into Pt dish, and add rapidly, with continuous stirring, 50 mL of the alc. KCl-Na<sub>2</sub>CO<sub>3</sub> reagent. Do not let soln become acid, and if necessary, use more reagent to insure alky. Continue stirring until all sol. portions of sample dissolve. Proceed as in **6.022**, beginning: "Filter thru gooch ..." Calc. % Na<sub>2</sub>SiF<sub>6</sub> (1 mL 0.2*N* NaOH = 0.009403 g Na<sub>2</sub>SiF<sub>6</sub>).

#### CONTAMINATION BY ORGANOCHLORINE PESTICIDES (10)—OFFICIAL FINAL ACTION

#### AOAC-CIPAC Method

(Applicable to detection of contamination by 0.01% chlorinated hydrocarbons such as aldrin, DDT, dieldrin, and endrin, and 0.05–0.10% of chlordane, Strobane, and toxaphene)

#### 6.027

#### Apparatus

(a) *Thin layer chromatographic apparatus.*—See **29.006**.  
(b) *Ultraviolet apparatus.*—Sterilamp G-15T8 (Westinghouse Electric Corp., Lamp Divisions, One Westinghouse Plaza, Bloomfield, NJ 07003).

#### 6.028

#### Reagents

(a) *Adsorbent.*—Aluminum oxide G, Type E (Brinkmann Instruments, Inc.).

(b) *Mobile solvents.*—(1) *n*-Hexane, (2) *n*-hexane-acetone (98+2), and (3) *n*-hexane-alcohol (98+2).

(c) *Pesticide std solns.*—1 μg/μL EtOAc, acetone, or any convenient solv.

#### 6.029

#### Preparation of Sample

Ext 8 g sample with 20 mL acetone in 250 mL erlenmeyer by shaking intermittently 5 min. Let solids settle. If soln is turbid, filter or centr. to obtain clear supernate for spotting. For samples contg large amts *S*, use 8 g sample and 20 mL pet ether.

#### 6.030

#### Preparation of Plates

Dissolve 0.1–0.15 g AgNO<sub>3</sub> in 1–2 mL H<sub>2</sub>O in 100 mL beaker, add 58 mL MeOH, and mix. Weigh 40 g adsorbent, (a), in 250 mL flask, add AgNO<sub>3</sub>-MeOH soln, and shake vigorously 20 sec. Apply slurry as 0.25 mm thick layer to five 20 × 20 cm (8 × 8") plates positioned on plastic mounting board. After plates appear dry, store in desiccator over desiccant. When plate is dry, scrape 1 cm strip from side edges to ensure even solv. front. Use plate immediately after removal from desiccator.

#### 6.031

#### Detection

Pour *n*-hexane into glass chromatgc tank to depth of 10–20 mm. Place 2 paper blotters (ca 7.5 × 22 cm) on each side of tank or large blotter covering back of tank and let equilibrate ≥2 hr before use.

Spot 10 μL sample ext on plate with 100 μL syringe. Do not disturb adsorbent layer. Also spot std solns of pesticides declared as part of formulation. Spots should be ≤6 mm diam. and placed <30 mm from bottom of plate. Place plate in chromatgc tank, and let plate develop ≥10 cm. Remove plate and expose to shortwave UV, **6.027(b)**. (Caution: See **51.016**.) Chlorinated org. pesticides should be visible as dark spots against white or light gray background. Expose plates ≥1 hr. Longer exposure will not harm plates.

To confirm identification of pesticide, repeat TLC step with different mobile solv., **6.028(b)(2)** or (3).

#### VOLATILITY OF ESTER FORMS OF HORMONE-TYPE HERBICIDES (11)—OFFICIAL FINAL ACTION

#### 6.032

#### Material

(a) *Paper bags.*—No. 20 to open with flat bottom. Close with paper clips.

(b) *Filter paper.*—7 cm diam.

(c) *Bacteriological loop.*—0.01 mL. Wash with acetone after each application or heat to cherry red in flame.

(d) *Test plants.*—Actively growing tomato seedlings 65–75 mm high in 3–4" pots.

(e) *Formulation to be tested.*—Use 0.01 mL aliquot of 4 lb/gal. formulation or equiv. vol. of other concns.

(f) *High and low volatile ester stds.*—Use Bu ester of 2,4-D as high volatile ester and tetrahydrofurfural ester of 2,4-D as low volatile ester with same wt of acid/gal. as formulations to be tested.

#### 6.033

#### Operating Technic

Open bags with flat bottom and place plant toward one side on bottom of bag. Apply 0.01 mL of formulation to middle of filter paper by means of bacteriological loop, and for controls, apply 0.01 mL solv. only. Place treated paper in bottom of bag. Do not touch treated part of paper against plant, sides of bag, or pot. Close bag by folding top, secure with clips, and let stand 24 hr at 85–110°F (29–43°C).

Use 3 plants per treatment and 3 for controls. Repeat test on another day.

Remove plants from bag, let stand 24 hr, and read curvature (stem bending, epinasty) response. (Fold and discard used bags to prevent contamination.) Rate plants according to scale as follows:

- (1) Normal growth of untreated check—no apparent response.
- (2) Epinasty 1–20° compared to normal—no curling.
- (3) Epinasty 21–40° compared to normal—slight curling.
- (4) Epinasty 41–60° compared to normal—moderate curling.
- (5) Epinasty 61–80° compared to normal—moderate curling.
- (6) Epinasty 81 to >90° compared to normal—severe formative effects.

Mean response of 1 to 2.4 for all tests indicates low volatility. Mean response of 2.5 to 6 indicates volatile formulation.

To detect small differences between low volatile esters, or differences between 2,4-D and 2,4,5-T types, hold plants 7 days after treatment to allow time for modified leaves or stem lesions to develop. Absence of such responses indicates that formulation was a low volatile 2,4,5-T ester.

## LEAD ARSENATE

(Caution: See 51.041 and 51.078.)

#### 6.042 Moisture—Official Final Action

(a) *Powder*.—Dry 2 g to const wt at 105–110°. Report loss in wt as  $\text{H}_2\text{O}$ .

(b) *Paste*.—Proceed as in (a), using 50 g. Grind dry sample to fine powder, mix well, transfer small portion to sample bottle, and again dry 1–2 hr at 105–110°. Use this anhyd. material to det. total Pb and total As.

#### Total Arsenic—Official Final Action

#### 6.043 Method I

See 6.007.

#### 6.044 Method II (15)

(Not applicable in presence of Sb)

Dissolve 1 g powd sample with  $\text{HNO}_3$  (1+4) in porcelain casserole or evapg dish, add 5 mL  $\text{H}_2\text{SO}_4$ , and heat on hot plate to copious evolution of white fumes. Cool, add little  $\text{H}_2\text{O}$ , and again evap. until white fumes appear, to assure removal of last trace of  $\text{HNO}_3$ . Wash into 200 mL vol. flask with  $\text{H}_2\text{O}$ , cool, dil. to vol., and filter thru dry filter. Transfer 100 mL filtrate to erlenmeyer and proceed as in 6.013, beginning "... add 1 g KI, ..." From mL std I soln used, calc. % total As as  $\text{As}_2\text{O}_5$ .

#### 6.045 Total Arsenious Oxide (16)—Official Final Action

Weigh 2 g powd sample and transfer to 200 mL vol. flask, add 100 mL  $\text{H}_2\text{SO}_4$  (1+6), and boil 30 min. Cool, dil. to vol., shake thoroly, and filter thru dry filter. Nearly neutze 100 mL filtrate with NaOH soln, 6.005(e), using few drops phthln. If neut. point is passed, make acid again with the dil.  $\text{H}_2\text{SO}_4$ . Continue as in 6.013, beginning "Neutze with  $\text{NaHCO}_3$ , ..." From mL std I soln used, calc. %  $\text{As}_2\text{O}_3$ .

#### Total Arsenic Oxide (17)—Official Final Action

#### 6.046

#### Reagents

(a) *Potassium iodide soln*.—Dissolve 20 g KI in  $\text{H}_2\text{O}$  and dil. to 100 mL.

(b) *Thiosulfate std soln*.—0.05N. Prep. daily by dilg 0.1N soln, 50.037–50.038. 1 mL 0.05N  $\text{Na}_2\text{S}_2\text{O}_3$  = 2.873 mg  $\text{As}_2\text{O}_5$ .

#### 6.047

#### Determination

Weigh 0.5 g powd sample and transfer to erlenmeyer. Add 25–30 mL HCl and evap. to dryness on steam bath. Add 50 mL HCl and if necessary to effect soln, heat on steam bath, keeping flask covered with watch glass to prevent evapn of acid. Cool to 20–25°, add 10 mL of the KI soln and 50 mL (or more if necessary to produce clear soln) 25%  $\text{NH}_4\text{Cl}$  soln, and immediately titr. liberated I with std  $\text{Na}_2\text{S}_2\text{O}_3$  soln. When color becomes faint yellow, dil. with ca 150 mL  $\text{H}_2\text{O}$  and continue titrn carefully, dropwise, until colorless, using starch indicator, 6.005(f), near end point. From mL  $\text{Na}_2\text{S}_2\text{O}_3$  soln used, calc. %  $\text{As}_2\text{O}_5$ .

#### 6.048 Water-Soluble Arsenic—Official Final Action

Proceed as in 6.013, and calc. results as  $\text{As}_2\text{O}_5$ .

#### 6.049 Total Lead (18)—Official Final Action

In 600 mL beaker on hot plate heat 0.5 g powd sample and ca 25 mL  $\text{HNO}_3$  (1+4). Filter to remove any insol. residue. Dil. to  $\geq 400$  mL, heat nearly to bp, and add  $\text{NH}_4\text{OH}$  to slight pptn, then

HNO<sub>3</sub> (1+9) to redissolve ppt, adding 1–2 mL excess. Into this soln, kept almost boiling, pipet 50 mL hot 10% K<sub>2</sub>CrO<sub>4</sub> soln, stirring constantly. Decant while hot thru weighed gooch, previously heated to 140–150°, and wash ppt several times by decanting and then on filter with boiling H<sub>2</sub>O until washings are colorless. Dry PbCrO<sub>4</sub> at 140–150° to const wt. From wt PbCrO<sub>4</sub>, calc. % Pb, using factor 0.6411. (PbCrO<sub>4</sub> ppt may contain small amt PbHAsO<sub>4</sub>, which will cause slightly high results, but this error rarely is >0.1–0.2%.)

#### CALCIUM ARSENATE

(Caution: See 51.041.)

##### 6.050 Moisture—Official Final Action

See 6.004.

##### 6.051 Total Arsenic—Official Final Action

See 6.007.

##### 6.052 Total Arsenious Oxide (19)—Official Final Action

(a) *Not applicable in presence of nitrates.*—Weigh 1 g sample, transfer to 500 mL erlenmeyer, and dissolve in 100 mL HCl (1+3). Heat to 90° and titr. with std KBrO<sub>3</sub> soln, 6.005(c), using 10 drops Me orange, 6.005(g). From mL std KBrO<sub>3</sub> soln used, calc. % As<sub>2</sub>O<sub>3</sub>.

(b) *Applicable in presence of small amounts of nitrates.*—Proceed as in (a) except to titr. at room temp.

##### 6.053 Water-Soluble Arsenic—Official Final Action

Proceed as in 6.013, and calc. results as As<sub>2</sub>O<sub>3</sub>. (In testing Ca arsenate by this method, low value for H<sub>2</sub>O-sol. As is not assurance against plant injury when using this product.)

#### Total Calcium (19)—Official Final Action

##### 6.054

##### Reagents

(a) *Ammonium oxalate soln.*—Dissolve 40 g (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub>·H<sub>2</sub>O in 1 L H<sub>2</sub>O.

(b) *Potassium permanganate std soln.*—0.1N. Prep. and stdze as in 50.025–50.026.

##### 6.055 Method I

Dissolve 2 g sample in 80 mL HOAc (1+3), transfer to 200 mL vol. flask, dil. to vol., and filter thru dry filter. Transfer 50 mL aliquot to beaker, dil. to ca 200 mL, heat to bp, and ppt Ca with (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln. Let beaker stand 3 hr on steam bath, filter, and wash ppt with hot H<sub>2</sub>O. Dissolve ppt in 200 mL H<sub>2</sub>O contg 25 mL H<sub>2</sub>SO<sub>4</sub> (1+4), heat to ca 70°, and titr. with std KMnO<sub>4</sub> soln. From mL KMnO<sub>4</sub> soln used, calc. % Ca.

##### 6.056 Method II

(Not applicable in presence of Pb. Caution: See 51.078.)

Weigh 2 g sample, transfer to beaker, add 5 mL HBr (ca 1.38 sp gr) and 15 mL HCl, and evap. to dryness under hood to remove As. Repeat treatment, add 20 mL HCl, and again evap. to dryness. Take up with H<sub>2</sub>O and little HCl, filter into 200 mL vol. flask, wash, and dil. to vol. Transfer 50 mL aliquot to beaker, add 10 mL HCl and few drops HNO<sub>3</sub>, boil, and make slightly alk. with NH<sub>4</sub>OH. Let stand few min and filter. Dissolve ppt in HCl (1+4), reppt, filter thru same paper, and wash with hot H<sub>2</sub>O. To combined filtrates and washings add 20 mL HOAc (1+3) and adjust to ca 200 mL. Heat to bp, ppt with (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln, and

let stand 3 hr on steam bath. Filter, and wash with hot H<sub>2</sub>O. Ignite at 950°, and weigh as CaO; or dissolve and titr. as in 6.055. From wt CaO or mL KMnO<sub>4</sub> soln used, calc. % Ca.

#### COPPER NAPHTHENATE

(Caution: See 51.041.)

#### Copper (20)—Official First Action

##### 6.065 Titrimetric Method

Accurately weigh sample contg ca 0.2 g Cu into dry g-s flask. Add 5 mL pet ether to concd products. Add 100 mL H<sub>2</sub>O, 1.5 g NH<sub>4</sub>HF<sub>2</sub>, and 5–10 g KI. Stopper and shake vigorously until reaction is complete (usually ca 2 min). Wash stopper and sides of flask with H<sub>2</sub>O and titr. with std 0.1N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> (stdzd against Cu) to light brown. Add starch indicator, 6.005(f), titr. almost to end point, add 2 g KSCN, shake to dissolve, and complete titrn to starch end point.

##### 6.066 Electrolytic Method

Accurately weigh sample contg ca 0.2 g Cu into 200 mL separator. Add 50 mL pet ether and 25 mL HNO<sub>3</sub> (1+4), and shake 2 min. Drain aq. phase into 250 mL beaker and save. Wash pet ether with 15 and 10 mL HNO<sub>3</sub> (1+4), and combine acid exts. Neutze with NH<sub>4</sub>OH, acidify with 6 mL H<sub>2</sub>SO<sub>4</sub> and 4 mL HNO<sub>3</sub>, and proceed as in 6.015, beginning "... adjust vol. to 200 mL, ..." using ca 0.5 amp during first 10 min and 1.5–2.0 amp for ca 20 min.

★ Methods for this product are surplus—see inside front cover.

**BORDEAUX MIXTURE**

(Caution: See 51.041.)

**6.067 Moisture—Official Final Action**(a) *Powder*.—See 6.042(a).

(b) *Paste*.—Heat ca 100 g in oven at 90–100° until dry enough to powder readily and note loss in wt. Powder this partially dried sample and det. remaining H<sub>2</sub>O in 2 g as in (a). Det. CO<sub>2</sub> as in 6.069, both in original paste and in partially dried sample. Calc. total H<sub>2</sub>O by following formula:

$$M = a + \frac{(100 - a)(b + c)}{100} - d,$$

where  $M$  = % total H<sub>2</sub>O in original paste;  $a$  = % loss in wt of original paste during first drying;  $b$  = % loss in wt of partially dried paste during second drying;  $c$  = % CO<sub>2</sub> remaining in partially dried paste after first drying; and  $d$  = % total CO<sub>2</sub> in original paste.

**Carbon Dioxide (27)—Official Final Action****6.068****Apparatus**

Use 200 mL erlenmeyer with 2-hole stopper; in one hole fit dropping funnel with stem extending almost to bottom of flask, and thru other hole pass outlet of condenser that is inclined upward at 30° angle from horizontal. Connect upper end of condenser with CaCl<sub>2</sub> tube, which in turn connects with double U-tube filled in middle with pumice fragments, previously satd with 20% CuSO<sub>4</sub>·5H<sub>2</sub>O soln and subsequently dehydrated, and with CaCl<sub>2</sub> at either end. Connect 2 weighed U-tubes to absorb CO<sub>2</sub>, first filled with porous soda-lime, and second, 1/3 with soda-lime and 2/3 with CaCl<sub>2</sub>, placing the CaCl<sub>2</sub> at exit end of train. Attach Geissler bulb, partly filled with H<sub>2</sub>SO<sub>4</sub>, to last U-tube to show rate of gas flow, and connect aspirator with Geissler bulb to draw air thru app. Connect absorption tower filled with soda-lime to mouth of dropping funnel to remove CO<sub>2</sub> from air entering app.

**6.069****Determination**

Weigh 2 g powder or 10 g paste into the erlenmeyer and add ca 20 mL H<sub>2</sub>O. Attach flask to app., omitting the 2 weighed U-tubes, and draw CO<sub>2</sub>-free air thru app. until it displaces original air. Attach weighed U-tubes as in 6.068, close stopcock of dropping funnel, pour into it 50 mL HCl (1+4), reconnect with soda-lime tower, and let acid flow into erlenmeyer, slowly if there is much CO<sub>2</sub>, rapidly if there is little. When effervescence diminishes, place low Bunsen flame under flask and start flow of H<sub>2</sub>O thru condenser, letting slow current of air flow thru app. at same time. Maintain steady but quiet boil and slow air current thru app. Boil few min after H<sub>2</sub>O begins to condense, remove flame, and continue air flow at ca 2 bubbles/sec until app. is cool. Disconnect weighed absorption tubes, cool in balance case, and weigh. Increase in wt = CO<sub>2</sub>.

**Copper—Official Final Action****6.070 Electrolytic Method**(Also applicable to CuCO<sub>3</sub> and CuSO<sub>4</sub>)

Dissolve powd sample contg 0.2–0.25 g Cu in 45 mL HNO<sub>3</sub> (1+4). Filter if necessary, dil. to 200 mL, and electrolyze as in 6.015.

**6.071 Volumetric Thiosulfate Method**

Dissolve 2 g powd sample in ca 25 mL HNO<sub>3</sub> (1+4), dil. to 50 mL, add NH<sub>4</sub>OH in excess, and heat. Without removing ppt that

has formed, boil off excess NH<sub>3</sub>, add 3–4 mL HOAc, cool, add 10 mL 30% KI soln, and titr. as in 6.016, beginning "... titr. with std Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, ..."

See 4.092, 10th ed.**LIME SULFUR SOLUTIONS AND DRY LIME SULFUR****Soluble Sulfur (27)—Official Final Action**

(Use low S reagents.)

**6.103****Preparation of Sample**

(a) *Solns.*—Accurately weigh ca 10 g soln, transfer to 250 mL vol. flask, and immediately dil. to vol. with recently boiled and cooled  $H_2O$ . Mix thoroly and either take necessary aliquots in individual pipets in min. time for detns or transfer to small bottles, filling them completely and avoiding contact of soln with air as much as possible. Stopper bottles, seal with paraffin, and store in dark, cool place.

(b) *Dry lime-sulfur.*—Thoroly stir 5 g sample with ca 50 mL  $H_2O$  in 250 mL beaker. Let settle and decant thru paper into 250 mL vol. flask. Repeat extn with  $H_2O$  until filtrate is colorless and ca 200 mL is obtained. Transfer residue to paper, wash with hot  $H_2O$ , cool to room temp., and dil. to vol. Dry residue 1.5 hr at  $105^\circ$ , and reserve for free S and sulfite S detns in residue, if desired. (Ext S from dry residue with  $CS_2$  (Caution: See 51.039, 51.040, and 51.048), evap. on steam bath or in air current, dry 15 min at  $105^\circ$ , weigh, and calc. % S.)

Prep. soln in min. time and keep beaker and funnel covered as much as possible.

**6.104****Determination**

With clean, dry pipet transfer 10 mL prepd soln, 6.103(a) or (b), to 250 mL beaker. Partially cover with cover glass and add 2–3 g  $Na_2O_2$  in small portions, with stirring, from tip of spatula. Continue adding  $Na_2O_2$  until all S appears to be oxidized to sulfate (yellow color disappears). Add slight excess  $Na_2O_2$ , completely cover beaker with cover glass, and heat on steam bath, stirring occasionally, 15–20 min.

Wash off cover glass and sides of beaker, acidify with HCl (1+4), and filter if necessary. Dil. to 150–200 mL, heat to bp, and add 10%  $BaCl_2$  soln (11 mL/1 g  $BaSO_4$ ), with const stirring, at such rate that ca 4 min is required to add necessary amt. Let stand until clear and cool, filter thru quant. paper, wash until Cl-free, ignite carefully, and heat to const wt over Bunsen burner. Calc. % S from wt  $BaSO_4$ , using factor 0.1374.

★ Methods for this product are surplus—see inside front cover.

**Thiosulfate Sulfur (27)—Official Final Action****6.105****Reagent**

*Ammoniacal zinc chloride soln.*—Dissolve 50 g  $\text{ZnCl}_2$  in ca 500 mL  $\text{H}_2\text{O}$ , add 125 mL  $\text{NH}_4\text{OH}$  and 50 g  $\text{NH}_4\text{Cl}$ , and dil. to 1 L.

**6.106****Determination**

To 50 mL  $\text{H}_2\text{O}$  in 200 mL vol. flask add 50 mL prep'd soln, **6.103(a)** or **(b)**. Add slight excess of the ammoniacal  $\text{ZnCl}_2$  soln and dil. to vol. Complete detn as rapidly as possible. Shake thoroly and filter thru dry filter. To 100 mL filtrate add few drops Me orange, **6.005(g)**, or Me red, **2.055(i)**, and exactly neutze with 0.1N HCl. Titr. neut. soln with 0.05N I, **6.005(b)**, using few drops starch indicator, **6.005(f)**. From mL I soln used, calc. % thiosulfate S present. (Factor of I soln in terms of  $\text{As}_2\text{O}_3 \times 1.296 = \text{equiv. in thiosulfate S.}$ )

**Sulfide Sulfur—Official Final Action****6.107 Zinc Chloride Method (27)**

To 10–15 mL  $\text{H}_2\text{O}$  in small beaker add 10 mL aliquot prep'd soln, **6.103(a)** or **(b)**. Calc. amt ammoniacal  $\text{ZnCl}_2$  soln, **6.105**, necessary to ppt all S in aliquot and add slight excess. Stir thoroly, filter, wash ppt twice with cold  $\text{H}_2\text{O}$ , and transfer paper and ppt to beaker in which pptn was made. Cover with  $\text{H}_2\text{O}$ , disintegrate paper with glass rod, and add ca 3 g  $\text{Na}_2\text{O}_2$ , keeping beaker well covered with watch glass. Warm on steam bath with frequent shaking until all S is oxidized to sulfate, adding more  $\text{Na}_2\text{O}_2$  if necessary. Acidify slightly with HCl (1+4), filter to remove shreds of paper, wash thoroly with hot  $\text{H}_2\text{O}$ , and det. S in filtrate as in **6.104**.

**6.108 Indirect Method**

Difference between sol. S and sum of thiosulfate S and sulfide S = sulfide S.

**6.109 Sulfate Sulfur—Official Final Action**

Slightly acidify soln from **6.106** with HCl (1+4) and heat to bp. Add slowly, with const stirring, slight excess 10%  $\text{BaCl}_2$  soln, boil 30 min, let stand overnight, and filter. Calc. S from wt  $\text{BaSO}_4$ , and report as % sulfate S.

**6.110 Total Calcium (27)—Official Final Action**

To 25 mL prep'd soln, **6.103(a)** or **(b)**, add 10 mL HCl, evap. to dryness on steam bath, and  $\text{H}_2\text{O}$  and few mL HCl (1+4), warm until all  $\text{CaCl}_2$  dissolves, and filter to remove S and any  $\text{SiO}_2$  present. Dil. filtrate to 200–250 mL, heat to bp, add few mL  $\text{NH}_4\text{OH}$  in excess, and then add excess sat'd  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  soln. Continue boiling until pptd  $\text{CaC}_2\text{O}_4$  assumes well defined granular form, let stand 1 hr, filter, and wash few times with hot  $\text{H}_2\text{O}$ . Ignite at  $950^\circ$  in Pt crucible to const wt (CaO) and calc. % Ca.  $\text{CaO} \times 0.7147 = \text{Ca.}$

**SODIUM HYPOCHLORITE SOLUTIONS (28)****Sodium Hypochlorite****Arsenious Oxide Titration Method—Official Final Action****6.111****Reagents**

(a) *Arsenious oxide std soln.*—0.1N. Prep. as in **50.005–50.006**.

(b) *Iodine std soln.*—Prep. as in **50.018**. Stdze against (a).

**6.112****Determination**

Transfer 20 mL sample to 1 L vol. flask and dil. to vol. Pipet 50 mL aliquot of mixt. into 200 mL erlenmeyer. Add excess  $\text{As}_2\text{O}_3$  soln and then decided excess  $\text{NaHCO}_3$ . Titr. excess  $\text{As}_2\text{O}_3$  with std I soln, using starch soln, **6.005(f)**, or the I as its own indicator. Subtract vol. I soln, corrected to 0.1N, from vol.  $\text{As}_2\text{O}_3$  soln used, and from this value and sp gr of soln, calc. % NaOCl. 1 mL 0.1N  $\text{As}_2\text{O}_3 = 0.003722$  g NaOCl.

**6.113 Available Chlorine—Official Final Action**

Calc. % available Cl from titrn, **6.112**. 1 mL 0.1N  $\text{As}_2\text{O}_3 = 0.003545$  g available Cl.

**6.114 Chloride Chlorine—Official Final Action**

Pipet 50 mL aliquot prep'd soln, **6.112**, into 200 mL erlenmeyer and add slight excess  $\text{As}_2\text{O}_3$  soln, **6.111(a)**, calcd from NaOCl titrn; add slight excess  $\text{HNO}_3$ , neutze with  $\text{CaCO}_3$ , and titr. with 0.1N  $\text{AgNO}_3$ , **50.027–50.029**, using  $\text{K}_2\text{CrO}_4$  soln, **50.028(b)**, or the  $\text{Ag}_3\text{AsO}_4$  formed in soln, as indicator. Det. blank on reagents and correct for any Cl found. From this corrected titrn and sp gr of sample, calc. % Cl. From this value subtract  $\frac{1}{2}$  the % available Cl. Difference = % chloride Cl.

**6.115 Sodium Hydroxide (29)—Official Final Action**

Stdze pH meter equipped with calomel and glass electrodes, using std pH 6.9 buffer soln, **50.007(d)**.

Place 50 mL 10%  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$  soln and 30 mL 3%  $\text{H}_2\text{O}_2$  soln in 250 mL beaker. Neutze to pH 7.5 with ca 0.1N NaOH, using pH meter. Add 10 mL sample from pipet, stir vigorously 1 min, and titr. to pH 7.5 with std'd 0.1N HCl, using pH meter.

% NaOH =  $(\text{mL HCl} \times \text{normality} \times 4.0) / (\text{mL sample} \times \text{sp gr})$

**6.116 ★ Carbon Dioxide—Official Final Action ★**

Evolution into std  $\text{Ba(OH)}_2$  soln. See **4.158–4.159**, 10th ed.

**CALCIUM HYPOCHLORITE AND BLEACHING POWDER (28)****Available Chlorine****6.117 Arsenious Oxide Titration Method Official Final Action**

Weigh 5–10 g thoroly mixed sample into porcelain mortar, add 30–40 mL  $\text{H}_2\text{O}$ , and triturate to smooth cream (high-test  $\text{Ca(OCl)}_2$  will dissolve readily and not form a cream). Add more  $\text{H}_2\text{O}$ , stir well with pestle, and let insol. residue settle few moments. Pour mixt. off into 1 L vol. flask, add more  $\text{H}_2\text{O}$ , and thoroly triturate sample and pour off as before. Repeat operation until all material is transferred to flask. Rinse mortar and pestle, catch wash  $\text{H}_2\text{O}$  in flask, dil. to vol., and mix. Without letting material settle, pipet 25–50 mL aliquot into 200 mL erlenmeyer. Add excess std  $\text{As}_2\text{O}_3$  soln, **6.111(a)**, and then decided excess of  $\text{NaHCO}_3$ . Titr. excess  $\text{As}_2\text{O}_3$  with std I soln, **6.111(b)**, using starch soln, **6.005(f)**, or I as its own indicator. Subtract vol. I soln, corrected to 0.1N, from vol.  $\text{As}_2\text{O}_3$  soln used, and calc. % available Cl. 1 mL 0.1N  $\text{As}_2\text{O}_3 = 0.003545$  g available Cl.

★ Surplus method—see inside front cover.

**CHLORAMINE T (28)****Active Chlorine****Arsenious Oxide Titration Method—Official Final Action****6.118****Determination**

Transfer 0.5 g sample to 300–500 mL erlenmeyer, dissolve in 50 mL H<sub>2</sub>O, and add excess std As<sub>2</sub>O<sub>3</sub> soln, **6.111(a)**, and 5 mL H<sub>2</sub>SO<sub>4</sub> (1+4). Add decided excess NaHCO<sub>3</sub> and titr. excess As<sub>2</sub>O<sub>3</sub> with std I soln, **6.111(b)**, using starch soln, **6.005(f)**, or I as its own indicator. From this titrn, calc. active Cl in sample. 1 mL 0.1*N* As<sub>2</sub>O<sub>3</sub> = 0.001773 g active Cl. (To convert active Cl to available Cl, multiply active Cl by 2.)

**6.119 Total Chlorine—Official Final Action**

Dissolve 0.5 g sample in 50 mL H<sub>2</sub>O in erlenmeyer and add slight excess std As<sub>2</sub>O<sub>3</sub> soln as calcd from active Cl titrn, **6.118**. Add 5 mL HNO<sub>3</sub> (1+4), neutze with CaCO<sub>3</sub>, and titr. with std AgNO<sub>3</sub>, **50.027–50.029**, using K<sub>2</sub>CrO<sub>4</sub>, **50.028(b)**, as indicator. Det. blank on reagents and correct for any Cl found. From corrected titrn, calc. % total Cl in sample. 1 mL 0.1*N* AgNO<sub>3</sub> = 0.003545 g Cl. If total Cl exceeds active Cl, NaCl is indicated.

**6.120 ★ Sodium—Official Final Action ★**

From wt sulfated ash. See **6.183**, 11th ed.

**MINERAL OILS****Unsulfonated Residue (30)—Official Final Action****6.121****Reagent**

(Caution: See **51.030** and **51.031**.)

**Fuming 38*N* sulfuric acid.**—In tared g-s bottle (2.5 L acid bottle is convenient) mix fuming H<sub>2</sub>SO<sub>4</sub> (free from N oxides) (*x*) with H<sub>2</sub>SO<sub>4</sub> (*y*) to obtain mixed acid (*z*), contg slightly >82.38% total SO<sub>3</sub>. Depending on strength of fuming acid available, use following proportions of 2 acids: 100 parts *x* (15–20% free SO<sub>3</sub>) to 50 parts *y*; 100 parts *x* (20–30% free SO<sub>3</sub>) to 75 parts *y*; or 100 parts *x* (50% free SO<sub>3</sub>) to 140 parts *y*. Mix thoroly (considerable heat is generated), let cool, and again weigh to det. amt mixed acid obtained. Det. exact strength of mixed acid (*z*) and also of reserve supply of acid (*y*) as follows:

Pour ca 50 mL into small beaker and fill ca 10 mL weighing bulb or pipet by slight suction, wiping off outside of bulb with moist, then with dry, cloth. Weigh on analytical balance and let acid flow slowly down sides of neck of 1 L vol. flask into ca 200 mL cold H<sub>2</sub>O. (These sizes of bulb and flask give final soln ca 0.5*N*.) When bulb has drained, wash all traces of acid into flask, taking precautions against loss of SO<sub>3</sub> fumes. Dil. to vol. and titr. from buret with std alkali, using same indicator as used in stdzg. Calc. SO<sub>3</sub> content of both acids, and add calcd amt of reserve acid (*y*) to amt of mixed acid (*z*) on hand to bring *z* to 82.38% total SO<sub>3</sub> (equiv. to 100.92% H<sub>2</sub>SO<sub>4</sub>). After adding required amt of *y*, again analyze mixed acid to make certain it is of proper concn (±0.15% H<sub>2</sub>SO<sub>4</sub>). Keep acid in small bottles or in special dispenser bottle (**37**) to prevent absorption of H<sub>2</sub>O from air.

**6.122****Determination**

Pipet 5 mL sample into 6" Babcock cream bottle, **16.157(a)**, either 9 g 50% or 18 g 30% type. To reduce viscosity of heavy oils, warm pipet after initial drainage by passing it several times thru flame; then drain thoroly. If greater accuracy is desired, weigh measured sample and calc. exact vol. from wt and sp gr.

Slowly add 20 mL 38*N* H<sub>2</sub>SO<sub>4</sub>, gently shaking or rotating bottle and taking care that temp. does not rise above 60°. Cool in ice-H<sub>2</sub>O if necessary. When mixt. no longer develops heat on shaking, agitate thoroly, place bottle in H<sub>2</sub>O bath, and heat 10 min at 60–65°, keeping contents of bottle thoroly mixed by shaking vigorously 20 sec at 2 min intervals. Remove bottle from bath and add H<sub>2</sub>SO<sub>4</sub> until oil is in graduated neck. Centrf. 5 min (or longer if necessary to obtain const vol. of oil) at 1200–1500 rpm. Read vol. of unsulfonated residue from graduations on neck of bottle and, to convert to mL, multiply reading from 9 g 50% bottle by 0.1 and reading from 18 g 30% bottle by 0.2. From result obtained, calc. % by vol. of unsulfonated residue.

**SOAP****Moisture (32)****6.123 Toluene Distillation Method—Official Final Action**

Weigh ca 20 g sample into 300–500 mL flask; add 50 mL toluene (tech. grade is satisfactory); and, to prevent foaming, add ca 10 g lump rosin (do not use powd). Distil into Dean and Stark type distg tube receiver and continue distn until no more H<sub>2</sub>O collects in receiver. Cool contents of tube to room temp., read vol. H<sub>2</sub>O under toluene in tube, and calc. % H<sub>2</sub>O.

**6.124 ★ Sodium and Potassium (33)—Official Final Action ★**

Removal of metal ions and P, and weighing as chlorides. See **6.094**, 11th ed.

**MINERAL OIL-SOAP EMULSIONS****Water (34)****6.125 Toluene Distillation Method—Official Final Action**

Weigh ca 25 g sample and proceed as in **6.123**, except use less rosin.

**6.126 Total Oil (35)—Official Final Action**

Weigh ca 10 g sample into Babcock cream bottle, **16.157(a)**. Dil. with ca 10 mL hot H<sub>2</sub>O and add 5–10 mL H<sub>2</sub>SO<sub>4</sub> (1+1). Heat in hot H<sub>2</sub>O bath ca 5 min to hasten sepn of oil, add enough satd NaCl soln to bring oil layer within graduated neck of bottle, centrf. 5 min at 1200 rpm, and let cool. Read vol. of oil layer, det. density, and from these values calc. wt and %. From this % value deduct % fatty acids (and phenols if present), detd sep., to obtain % oil.

**6.127 Soap (34)—Official Final Action**

(Error will result if apparent mol. wt of fatty acids varies appreciably from that of oleic acid.)

Weigh 20 g sample into separator, add 60 mL pet ether, and ext mixt. once with 20 mL and 4 times with 10 mL 50% alcohol. Break emulsion if necessary by letting 1 or 2 mL 20% NaOH soln run down wall of separator. Then gently swirl separator and let stand few min. Drain alc. layers and wash successively thru pet ether contained in 2 other separators. Combine alc. exts in beaker and evap. on steam bath to remove alcohol. Dissolve residue in ca 100 mL H<sub>2</sub>O made alk. with NaOH. Transfer to separator, acidify with HCl or H<sub>2</sub>SO<sub>4</sub>, ext 3 times with Et ether, and wash ether exts twice with H<sub>2</sub>O. Combine ether exts, evap. in weighed beaker on steam bath, and weigh as fatty acids. From wt fatty acids, calc. % soap in sample as Na or K oleate.

**6.128 Unsulfonated Residues—Official Final Action**

Using 5 mL of the recovered oil, **6.126**, proceed as in **6.122**.

★ Surplus method—see inside front cover.

**6.129 Ash (36)—Official Final Action**

Evap. 10 g sample, or more if necessary, in Pt dish. Ignite, and leach charred mass with  $\text{H}_2\text{O}$ . Ignite residue, add leachings, evap. to dryness, ignite, and weigh. From this wt, calc. % ash. Test ash for Cu, Ca,  $\text{CaF}_2$ , etc.

**ORGANIC MERCURIAL SEED DISINFECTANTS****Mercury****6.130 ★ Volatilization Method (37) ★  
Official Final Action**

See 4.150–4.151, 10th ed. (*Caution: See 51.041 and 51.065.*)

**6.131 ★ Precipitation Method (37) ★  
Official Final Action**

Digestion with  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{O}_2$  and pptn as  $\text{HgS}$ . See 6.173, 11th ed.

**Titrimetric Method (38)—Official Final Action****6.132 Principle**

Sample is digested under  $\text{H}_2\text{O}$ -cooled condenser with fuming  $\text{H}_2\text{SO}_4$ -fuming  $\text{HNO}_3$ . Hg is detd by titrn with std  $\text{SCN}$  soln with ferric alum as indicator. Small amts of chloride are oxidized to Cl and expelled thru condenser. Not applicable in presence of large amts of Cl-contg materials.

**6.133 Reagents**

(a) *Ferric indicator*.—Dissolve 8 g  $\text{FeNH}_4(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$  in 80 mL  $\text{H}_2\text{O}$ . Add enough  $\text{HNO}_3$  to destroy brown Fe color and dil. to 100 mL with  $\text{H}_2\text{O}$ .

(b) *Ferrous sulfate soln*.—Dissolve 1 g  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 1 mL  $\text{H}_2\text{SO}_4$ , and dil. to 100 mL with  $\text{H}_2\text{O}$ . Prep. fresh for each detn.

**6.134 Preparation of Sample**

(a) *Solns*.—Mix thoroly and weigh, by difference, amt sample (max. 10 g) contg preferably 0.07 g Hg into 500 mL  $\text{Erlenmeyer}$ .

(b) *Dusts*.—Mix thoroly and, using glass weighing dish, weigh amt sample as in (a). Transfer thru powder funnel into 500 mL  $\text{Erlenmeyer}$ .

**6.135 Determination**

(*Caution: Conduct detn in well ventilated hood. Method is dangerous in presence of material which reacts violently with  $\text{H}_2\text{SO}_4$  and/or  $\text{HNO}_3$ . See 51.019, 51.026, 51.030, 51.031, and 51.079.*)

Connect straight-tube,  $\text{H}_2\text{O}$ -cooled condenser to erlenmeyer contg sample. Place flask in cold  $\text{H}_2\text{O}$  bath. Carefully add 10 mL  $\text{H}_2\text{SO}_4$  thru top of condenser and mix by swirling. Add in small portions, swirling after each addn, 30–40 mL fuming  $\text{H}_2\text{SO}_4$  (20% free  $\text{SO}_3$ ) thru top of condenser, followed by 10 mL red fuming  $\text{HNO}_3$  (98%  $\text{HNO}_3$ ). Remove from bath and dry outside of flask. Heat with small flame to reflux at ca 30 drops/min with red fumes persisting in flask and condenser. Heat 30 min; if small amt chloride is present, heat 2 hr with occasional addn of fuming  $\text{HNO}_3$  as required. Cool, and add 100 mL cold  $\text{H}_2\text{O}$  slowly thru top of condenser while cooling flask in cold  $\text{H}_2\text{O}$  bath. Add 2 or 3 glass beads or boiling chips and boil until N oxides have been expelled to top of condenser (ca 2 min). Wash condenser with 50 mL cold  $\text{H}_2\text{O}$ , disconnect flask, and add satd  $\text{KMnO}_4$  soln

until color remains purple. (If large amts insol. material are present, filter hot soln thru medium tight asbestos mat in gooch before addn of  $\text{KMnO}_4$ . Wash flask and filter 5 times with hot  $\text{H}_2\text{O}$ , and then add  $\text{KMnO}_4$ .) Cool flask, and destroy  $\text{KMnO}_4$  with fresh 1%  $\text{FeSO}_4$  soln. Add 10 mL ferric indicator and titr. with 0.1N  $\text{NH}_4\text{SCN}$  or  $\text{KSCN}$ , 50.003–50.004, to appearance of first permanent faint orange. 1 mL 0.1N  $\text{NH}_4\text{SCN}$  or  $\text{KSCN}$  = 0.01003 g Hg.

**AOAC-CIPAC Gravimetric Method (39)—Official Final Action**

(Applicable in presence of large amts Cl-contg materials; not applicable to chloro- or nitrophenols nor to materials not decomposed by digestion mixt.)

**6.136 Reagents**

(a) *Dilute sulfuric acid*.—Add 30 mL  $\text{H}_2\text{SO}_4$  to  $\text{H}_2\text{O}$  in 100 mL vol. flask, cool, and dil. to vol. with  $\text{H}_2\text{O}$ .

(b) *Sodium sulfite soln*.—10%. Dissolve 10 g  $\text{Na}_2\text{SO}_3$  in  $\text{H}_2\text{O}$  in 100 mL vol. flask and dil. to vol. with  $\text{H}_2\text{O}$ .

(c) *Ammonium citrate soln*.—pH 7.0. See 2.044(a).

(d) *Precipitating reagent*.—Add 20 mL 1,2-propanediamine (Eastman Kodak Co., P3170) to 100 mL 1M  $\text{CuSO}_4$  soln. Store in g-s container.

(e) *Wash soln*.—Add 1 g KI and 2 mL pptg reagent to 1 L  $\text{H}_2\text{O}$ .

**6.137 Preparation of Sample**

(a) *Solns*.—Mix thoroly and weigh, by difference, sample (max. 5 g) contg 0.02–0.08 g Hg into 125 mL  $\text{Erlenmeyer}$ .

(b) *Dusts*.—Mix thoroly and, using glass weighing dish, weigh sample as in (a). Transfer thru powder funnel into 125 mL  $\text{Erlenmeyer}$ .

**6.138 Determination**

(*Caution: Conduct detn in well ventilated hood.*)

Add to sample in following order: 5 mL ethylene glycol, swirling to thoroly suspend solids, 4 g KI, 10 mL dil.  $\text{H}_2\text{SO}_4$ , 0.4 g I, and 2 glass beads. After thoro mixing, connect straight-tube,  $\text{H}_2\text{O}$ -cooled condenser and, with low flame, heat to slight boil so that liq. condenses in lower portion of condenser. Swirl occasionally, avoiding excessive heat and crystn of large amt I in condenser. Reflux 1 hr and, while cooling flask in  $\text{H}_2\text{O}$  bath, immediately wash warm condenser with heavy stream of ca 25 mL  $\text{H}_2\text{O}$ . (If dye or I persists in condenser, loosen by reheating flask contents, without  $\text{H}_2\text{O}$  in condenser, until liq. refluxes slightly beyond adhering material. Wash condenser again with ca 25 mL  $\text{H}_2\text{O}$ , and cool flask.) Disconnect condenser and wash connections directly into flask. Add ca 2 mL 10%  $\text{Na}_2\text{SO}_3$  dropwise, with swirling, until I color slightly lightens. (Excess I must be present.) Neutze soln with  $\text{NH}_4\text{OH}$ , using pH test paper, until very slightly alk. (pH 7.0–7.3). Cool, and filter with vac. thru retentive paper (S&S Blue Ribbon, or equiv.) in buchner into 400 mL beaker. Wash flask and paper thoroly, keeping total filtrate <150 mL. Add 50 mL  $\text{NH}_4$  citrate soln, bring mixt. just to bp, and stir in 5 mL pptg reagent. Cool and let stand  $\geq 2$  hr (preferably overnight); filter thru medium porosity glass crucible, previously dried at  $105^\circ$  and weighed. Transfer ppt with wash soln, and wash with same soln several times. Rinse I from ppt with ca 25 mL alcohol in 5 mL portions (some samples may require up to 50 mL) until filtrate is colorless. (Let alcohol stand few min with occasional swirling after each addn before applying suction. Ppt should be suspended in liq. each time.) Wash ppt with three 5 mL portions  $\text{CHCl}_3$ , suspending ppt each time as above until dye and pesticides are completely removed. Finally wash with 5 mL alcohol, dry 30 min at  $105^\circ$ , cool, and weigh.

Wt Hg = wt ppt  $\times 0.218$ .

★ Surplus method—see inside front cover.

## ANT POISONS AND RODENTICIDES

6.139 ★ **Alpha-Naphthylthiourea (40)** ★  
Official First Action

(Caution: See 51.039, 51.041, and 51.046.)

N detn. See 4.132, 10th ed.

6.140 **Thallous Sulfate (41)**—Official Final Action

(Caution: See 51.019, 51.026, 51.031, and 51.041.)

Weigh sample contg 0.1–0.15 g  $\text{Ti}_2\text{SO}_4$  (usually 10 g), transfer to 800 mL Kjeldahl flask, and add 25 mL  $\text{H}_2\text{SO}_4$  followed by 5–10 mL  $\text{HNO}_3$ . After first violent reaction ceases, heat until white fumes of  $\text{H}_2\text{SO}_4$  appear. Add few drops fuming  $\text{HNO}_3$  and continue heating and adding  $\text{HNO}_3$  until org. matter is destroyed, as shown by colorless or light yellow soln. Cool, add 10–15 mL  $\text{H}_2\text{O}$ , again cool, and wash contents of flask into 400 mL beaker, continuing washing until vol. is 60–70 mL. Boil several min to remove all  $\text{HNO}_3$ , cool, and filter into 400 mL beaker. Wash with hot  $\text{H}_2\text{O}$  until vol. in beaker is 175 mL, neutze with  $\text{NH}_4\text{OH}$ , and then slightly acidify with  $\text{H}_2\text{SO}_4$  (1+4). Add 1 g  $\text{NaHSO}_3$  to ensure reduction of thallic to thallous state. Heat to bp, add 50 mL 10%  $\text{KI}$  soln, stir, and let stand overnight. Filter thru tight gooch contg 2 disks S&S 589 white ribbon paper covered by medium pad of asbestos. Wash 4 or 5 times with 10 mL portions 1%  $\text{KI}$  soln, and finally with absolute alcohol. Dry to const wt at  $105^\circ$  (1–1.5 hr), and weigh as TII.

$$\% \text{Ti}_2\text{SO}_4 = (\text{g TII} \times 0.7619 \times 100) / \text{g sample.}$$
**Warfarin (3-( $\alpha$ -Acetonylbenzyl)-4-hydroxycoumarin) (42)**  
Official Final Action

(Applicable to baits contg ca 0.025% and to concs contg  $\geq 0.5\%$  warfarin. Not applicable to pelleted baits or baits consisting of cracked corn treated with alc. warfarin soln and aq. sugar soln, and then dried.)

## 6.141

## Reagents

(a) *Sodium pyrophosphate soln.*—1%. Dissolve 5 g  $\text{Na}_4\text{P}_2\text{O}_7 \cdot 10\text{H}_2\text{O}$  in 500 mL  $\text{H}_2\text{O}$ .

(b) *Petroleum ether, purified.*—Ext 200 mL pet ether with three 20 mL portions 1%  $\text{Na}_4\text{P}_2\text{O}_7$  soln.

(c) *Warfarin std soln.*—10  $\mu\text{g/mL}$ . Dissolve 100 mg pure warfarin (Wisconsin Alumni Research Foundation, P.O. Box 7365, Madison, WI 53707) in 100 mL 1%  $\text{Na}_4\text{P}_2\text{O}_7$  soln. Dil. 10 mL to 100 mL with 1%  $\text{Na}_4\text{P}_2\text{O}_7$  soln, and dil. 10 mL of second soln to 100 mL with 1%  $\text{Na}_4\text{P}_2\text{O}_7$  soln.

## 6.142

## Determination

Weigh 10 g sample (0.025%), 0.600 g (0.5%), or equiv. wt of higher concn, into 125 mL g-s flask or 100 mL centr. tube and add 50 mL Et ether from pipet. Stopper tightly and shake mech. ca 30 min. Transfer 5 or 10 mL to centr. tube (or centr. directly), stopper, and centr. 5 min at high speed or until clear. Take precautions to avoid evapn of ether.

Pipet 10 mL 1%  $\text{Na}_4\text{P}_2\text{O}_7$  soln into g-s 16  $\times$  150 mm test tube and add 2 mL centrfd ether ext from pipet. Stopper and shake vigorously 2 min. Centr. at high speed until aq. layer is clear. Draw off ether layer, including any emulsion that remains, using fine-tip glass tube attached to aspirator. Add ca 2 mL Et ether, shake vigorously, centr., and completely draw off ether layer. Repeat ether extn, and then ext twice with purified pet ether in same manner.

Prep. blank soln similarly, using 2 mL ether instead of 2 mL ether ext.

Det. A of aq. soln in 1 cm silica cell at 308 nm against blank soln in Beckman spectrophtr, model DU (replaced by models 24/25), or equiv. Det. A' (ca 0.46) of the std warfarin soln against 1%  $\text{Na}_4\text{P}_2\text{O}_7$  soln.

$$\begin{aligned} \% \text{ Warfarin} &= (A/A') \times (10^{-5} \text{ g std/mL}) \\ &\quad \times [100 / (\text{g sample} \times (2/50)(1/10))] \\ &= (A/A') \times (0.250 / \text{g sample}). \end{aligned}$$

## FUMIGANTS

## Fumigant Mixtures (43)—Official First Action

(Applicable to org. components of  $\text{CS}_2$ ,  $\text{CCl}_4$ ,  $(\text{CH}_2)_2\text{Cl}_2$ , and  $(\text{CH}_2)_2\text{Br}_2$  mixts. *Precautions:* Handle with care in hood or well-ventilated area. Mixts are volatile, poisonous, and sometimes flammable and may be fatal if inhaled or swallowed. They cause skin and eye irritation. In case of contact, immediately remove contaminated clothing and flush affected area with copious amts of  $\text{H}_2\text{O}$ . Do not reuse clothing until free of contamination. Do not use containers or equipment of Al, Mg, or their alloys.)

## 6.143

## Principle

Components are detd by GLC. Peak area of each component is measured and compared to stds of same fumigant mixt. Precision of method is  $\pm 0.6\%$  for each component.

## 6.144

## Sampling

Obtain representative 1 L sample from container. Sample bulk containers by means of weighted bottle, lowered toward bottom and raised at such rate that it is  $\frac{3}{4}$  full when withdrawn. Sample drums or small containers with thief or thru tap or valve located so that sample comes from well below surface. Prevent contamination of product or sample.

Place sample in clean, dry, and solv. vapor-tight glass bottle of such size that it is nearly filled (not above shoulder) by sample. Vapor-tight g-s bottles or screw-cap bottles with Sn foil lined caps are satisfactory. Store samples at low temp.; cool to  $<18^\circ$  before opening for analysis.

## 6.145

## Apparatus

(a) *Gas chromatograph.*—With flame ionization or thermal conductivity detector. Typical operating conditions: Column temp.,  $110^\circ$ ; injection port temp.,  $200^\circ$ ; flow rate, 80 mL He/min.

(b) *Recorder.*—0.05–1.05 mv, full scale response. Integrator may be used.

(c) *Syringe.*—Hamilton Co. 10  $\mu\text{L}$  No. 701N, or equiv.

(d) *Column.*—1.2 m (4') stainless steel,  $\frac{1}{4}$ " od, 0.194" id, packed with reagent 6.146(a). Max. temp. is  $160^\circ$ . Other columns can be used but chromatgc conditions and sample size must be adjusted in accordance with column requirements. One such column is: 3 m (10') stainless,  $\frac{3}{16}$ " od, 0.12" id, packed with 20% by wt *N,N*-bis-(2-cyanoethyl) formamide on 80–100 mesh Chromosorb W, acid-washed. Columns are available from com. suppliers. Criterion for use is emergence of each component of mixt. of  $\text{CS}_2$ ,  $\text{CCl}_4$ ,  $(\text{CH}_2)_2\text{Cl}_2$ , and  $(\text{CH}_2)_2\text{Br}_2$  as sep. peak.

## 6.146

## Reagents

(a) *Column packing.*—30% by wt tricresyl phosphate on Chromosorb P, 30–60 mesh.

(b) *Carbon disulfide std.*—ACS.

(c) *Carbon tetrachloride std.*—ACS.

(d) *Ethylene dichloride std.*—Purified 1,2-dichloroethane, available from laboratory supply houses, or use center cut of fractionation of com. product.

(e) *Ethylene dibromide (1,2-dibromoethane) std.*—Purified or distd as in (d).

## 6.147

**Preparation of Standards**

Prep. fresh stds just before analysis which approximate expected composition, by wt, of fumigant mixt. Place proper wt of each component in 25 mL g-s vol. flask and mix well. Do not prep. by vol. Cool CS<sub>2</sub> to prevent loss. Adjust wt stds to detector response.

Carefully fill weighed 10 mL vol. flask to mark with prepd std and weigh. Use this wt to det. g/5  $\mu$ L values for each component of std.

## 6.148

**Determination**

Purge column thoroly at 110° before use. Establish 0 baseline at full sensitivity. Inject 5  $\mu$ L std fumigant mixt. into chromatograph. Attenuate successively so that each peak is at max. % of chart scale, adjusting sample size and attenuation, if necessary. Repeat injection. Detd area for each component, corrected for any baseline drift, should differ by  $\leq 1\%$ . Order of elution from column is: CS<sub>2</sub>, CCl<sub>4</sub>, (CH<sub>2</sub>)<sub>2</sub>Cl<sub>2</sub>, and (CH<sub>2</sub>)<sub>2</sub>Br<sub>2</sub>. Total analysis time is ca 21 min.

Inject 5  $\mu$ L sample into chromatograph. Det. corrected area of each component from chromatogram, or note integrator reading.

g Component =  $S \times C/B$ , where  $S$  = wt component in std,  $B$  = area for component in std, and  $C$  = area for component in sample. Perform calcn for each component in sample.

% Component = g component in sample  $\times 100$  / sum of g components in sample.

Last equation is not applicable in presence of unmeasured contaminants.

## PESTICIDES RELATED TO NATURAL PRODUCTS AND THEIR SYNERGISTS

### Technical Allethrin (44)—Official First Action

(Caution: See 51.041.)

## 6.149

**Principle**

Allethrin reacts quant. with ethylenediamine to form chrysanthemum monocarboxylic acid which is detd by titrn with std NaOMe in pyridine. Chrysanthemum monocarboxylic acid, anhydride, and acid chloride interfere quant. and are detd independently.

## 6.150

**Reagents**

(a) *Absolute alcohol*.—SDF No. 2-B is satisfactory.

(b) *Methanolic hydrochloric acid std soln.*—0.1N. Dil. 17 mL HCl (1+1) to 1 L with anhyd. MeOH. Stdze against std 0.1N NaOH, using phthln. If used at temp.,  $T$ , different from that at which stdzd,  $T_0$ , calc. corrected normality =  $N[1 - 0.001(T - T_0)]$ .

(c) *Sodium methylate std soln.*—0.1N in pyridine. Transfer 50 mL 2N NaOMe (Caution: See 51.038) to 1 L bottle contg 75 mL anhyd. MeOH and dil. to 1 L with redistd pyridine. Stdze against NBS benzoic acid, using pyridine as solv. and thymolphthalein, (i), as indicator. Dispense from 50 mL automatic buret with vents connected to Ascarite tubes. Stdze daily against std methanolic HCl, (b).

(d) *Methanolic potassium hydroxide std soln.*—0.02N. Dissolve 1.12 g KOH in 1 L MeOH. Stdze as in 50.035.

(e) *Morpholine soln.*—Transfer 8.7 mL redistd morpholine to 1 L bottle and dil. to 1 L with anhyd. MeOH. Fit bottle with 2-hole rubber stopper; thru 1 hole insert 20 mL pipet so that tip extends below surface of liq., and thru other hole insert short piece of glass tubing to which is attached aspirator bulb.

(f) *Ethylenediamine*.—Redistd com. grade contg  $< 3\%$  H<sub>2</sub>O.

Dispense from automatic buret with vents connected to Ascarite tubes.

(g) *Dimethyl yellow-methylene blue mixed indicator*.—Dissolve 1 g dimethyl yellow (*p*-dimethylaminoazobenzene; Caution: See 51.085) and 0.1 g methylene blue in 125 mL anhyd. MeOH.

(h)  *$\alpha$ -Naphtholbenzein indicator*.—1% alc. soln.

(i) *Thymolphthalein indicator*.—1% pyridine soln.

## 6.151

**Determination of Chrysanthemum Monocarboxylic Acid Chloride**

Add 8–10 drops mixed indicator, (g), to ca 150 mL anhyd. MeOH and add 0.1N HCl, (b), dropwise until soln appears reddish brown by transmitted light. Add 0.02N KOH, (d), dropwise until appearance of first green. Transfer 25 mL to each of three 125 mL g-s erlenmeyers, reserving 1 flask as ref. color for end point. Into each of other flasks add 1.5–2.5 g sample from weighing pipet, swirling flask while adding sample. Within 5 min, titr. with 0.02N KOH, (d), to first green end point, using blank as ref. color. Calc. milliequiv. chrysanthemum monocarboxylic acid chloride/g sample,  $C = V \times N/g$  sample, where  $V$  = mL  $N$  normal KOH required;

% Chrysanthemum monocarboxylic acid chloride =  $C \times 18.67$ .

## 6.152

**Determination of Chrysanthemum Monocarboxylic Acid**

Transfer 25 mL anhyd. alcohol to each of two 125 mL g-s erlenmeyers, add 8–9 drops  $\alpha$ -naphtholbenzein indicator, and cool to 0° in ice bath. Neutze by adding 0.02N NaOH dropwise to bright green end point. To each flask add 1.5–2.5 g sample from weighing pipet. Immediately titr. with 0.02N NaOH, 50.034, to first bright green end point. Calc. milliequiv. chrysanthemum monocarboxylic acid and acid chloride/g sample:  $D = X \times N/g$  sample, where  $X$  = mL  $N$  normal NaOH required;  $(D - C) \times 16.82$  = % chrysanthemum monocarboxylic acid.

## 6.153

**Determination of Chrysanthemum Monocarboxylic Anhydride**

Pipet 20 mL morpholine soln, (e), into each of four 250 mL erlenmeyers, using same pipet. Fill pipet by exerting pressure in bottle with aspirator bulb. Reserve 2 flasks for blanks; into each of other flasks add 1.5–2.5 g sample from weighing pipet. Swirl flasks and let samples and blanks stand 5 min at room temp. Add 4–5 drops mixed indicator, (g), to each flask and titr. with 0.1N HCl, (b), until color changes from green to faint red when viewed by transmitted light. Calc. milliequiv. chrysanthemum monocarboxylic anhydride/g sample:  $E = (B - Y) \times N/g$  sample, where  $Y$  = mL  $N$  normal HCl required for sample, and  $B$  = mL  $N$  normal HCl required for blank;  $(E - 2C) \times 31.84$  = % chrysanthemum monocarboxylic anhydride.

## 6.154

**Determination of Allethrin**

Add sample contg 0.8–1.1 g allethrin to each of two 250 mL erlenmeyers from weighing pipet. To each of 2 flasks as blanks and to samples add 25 mL ethylenediamine, (f), with swirling. Let samples and blanks stand 2 hr at 25 $\pm$ 2°. Wash down sides of flasks with 50 mL redistd pyridine. To each flask add 6–10 drops thymolphthalein indicator, (i), and titr. with 0.1N NaOMe, (c), to first permanent blue-green end point. (With colorless samples, first blue end point may be used.) Calc. milliequiv. allethrin/g sample:  $F = (Z - B) \times N/g$  sample, where  $Z$  = mL  $N$  normal NaOMe required for sample, and  $B$  = av. mL  $N$  normal NaOMe required for blank;  $(F + C - D - E) \times 30.24$  = % allethrin.

***d-trans*-Allethrin (dl-2-Allyl-4-hydroxy-3-methyl-2-cyclopentene-1 Ester of *d-trans*-2,2-Dimethyl-3-(2-methylpropenyl)cyclopropanecarboxylic Acid) (45)  
Official Final Action**

**Gas Chromatographic Method**

(Caution: See 51.041.)

**6.155**

**Principle**

*d-trans*-Allethrin is dild in acetone contg dibutyl phthalate as internal std. Ratios of GLC peak hts of *d-trans*-allethrin and dibutyl phthalate in sample and std are compared for quant. detn. Method is applicable to both tech. *d-trans*-allethrin and various formulations of it. Not applicable to formulations contg large amt MGK Repellent 874 (2-hydroxyethyl-*n*-octyl sulfide).

**6.156**

**Apparatus and Reagents**

(a) *Gas chromatograph*.—Equipped with flame ionization detector and 1.2 m (4') × 4 mm id glass column packed with 5% OV-1 (Analabs, Inc.) on 80–100 mesh Chromosorb W (HP). Operating conditions: temps (°)—column 165, injection port 230, detector 230; gas flows (mL/min)—N carrier gas 125, air 350–400, H 40–50; sensitivity—10<sup>-9</sup> amp full scale, attenuation 4× for tech. material, 10<sup>-9</sup> amp full scale, attenuation 1 for formulations. Before use, condition column 2–3 hr at 275° with N flow 50 mL/min. If necessary, vary column temp. or gas flow to attain retention times of ca 4 and 7 min for internal std and *d-trans*-allethrin, resp. Also vary detector sensitivity or injection vol. to attain ≥100 mm peak ht for each compd (ca 16 μg *d-trans*-allethrin). Theoretical plates/ft must be >200.

Calc. theoretical plates/ft (*N*) as follows:  $N = 16L^2/(M^2 \times F)$ , where *L* = retention of GLC peak in mm; *M* = peak baseline produced by drawing tangents to points of inflection of peak; and *F* = length of column (ft).

(b) *Internal std soln*.—4.0 mg dibutyl phthalate/mL acetone.

(c) *d-trans*-Allethrin std solns.—(1) *Soln 1*.—Approx. 4 mg/mL. Accurately weigh ca 1.0 g *d-trans*-allethrin (available from McLaughlin Gormley King Co., 8810 Tenth Ave N, Minneapolis, MN 55427) into 50 mL vol. flask and dil. to vol. with acetone. Pipet 20 mL this soln into 100 mL vol. flask, add 50 mL internal std soln by pipet, and dil. to vol. with acetone. Use this soln for detn of tech. material. (2) *Soln 2*.—Approx. 1 mg/mL. Pipet 25 mL *Soln 1* into 100 mL vol. flask and dil. to vol. with acetone. Use this soln for detn of *d-trans*-allethrin in formulations.

**6.157**

**Preparation of Sample**

(a) *Technical material*.—Accurately weigh sample contg ca 1.0 g *d-trans*-allethrin into 50 mL vol. flask and dil. to vol. with acetone. Pipet 20 mL aliquot into 100 mL vol. flask, add 50 mL internal std soln by pipet, and dil. to vol. with acetone.

(b) *Formulations*.—Accurately weigh sample contg ca 200 mg *d-trans*-allethrin into 50 mL vol. flask, add 25 mL internal std soln by pipet, and dil. to vol. with acetone. Pipet 25 mL aliquot into 100 mL vol. flask and dil. to vol. with acetone.

**6.158**

**Gas Chromatography**

(a) *Technical material*.—Inject aliquots (ca 3 μL) std *Soln 1* until ratio of *d-trans*-allethrin:dibutyl phthalate peak hts varies <1% for successive injections. Repeat with sample soln, followed by duplicate injections of std soln. If peak ht ratios differ >±1% from previous std injections, repeat series of injections.

(b) *Formulations*.—Proceed as in (a), using std *Soln 2*. Repeat std injections after each series of 3 sample injections. If peak ht ratios differ >±1.5% from previous std injections, repeat injections.

**6.159**

**Calculations**

(a) *Technical material*.—Calc. peak ht ratios for duplicate std injections before and after sample injections and average the 4 values. Calc. and average peak ht ratios for sample injections.

$$\% \text{ } d\text{-trans-Allethrin} = (W' \times P \times R)/(W \times R'),$$

where *W'* and *W* = g std and sample, resp.; *P* = % purity of std; and *R'* and *R* = peak ht ratios of std and sample, resp.

(b) *Formulations*.—Calc. av. for all std peak ht ratios and for sample peak ht ratios.

$$\% \text{ } d\text{-trans-Allethrin} = (W' \times P \times R \times 2)/(W \times R'),$$

where *W'* = g std in final diln.

**DERRIS AND CUBE POWDER**

**Rotenone**

**Crystallization Method (46)—Official Final Action**

(Caution: See 51.049 and 51.084.)

**6.160**

**Reagents**

(a) *Purified rotenone*.—Dissolve rotenone in boiling CCl<sub>4</sub>; cool in refrigerator or ice bath at 0–10° until pptn of rotenone-CCl<sub>4</sub> solvate stops. Filter thru buchner and wash once or twice with ice-cold CCl<sub>4</sub>. Conc. filtrate, crystallize, and filter as before. Transfer cryst. residue to beaker, add ca twice their vol. alcohol, and heat nearly to boiling. (Crystals need not dissolve completely.) Cool to room temp., filter thru buchner, and draw air thru cryst. residue until most alcohol is removed. Remove rotenone from funnel, dry in air, and finally heat 1 hr at 105°. Mp, detd in Pyrex, of purified material should be 163–164°. (Mother liquors may be concd and rotenone-CCl<sub>4</sub> solvate allowed to crystallize. Cryst. material may be used for further purification, or kept for prepn of wash solns or for seeding to induce crystn in detn.)

(b) *Rotenone-CCl<sub>4</sub> solvate*.—Ppt rotenone from CCl<sub>4</sub> soln, filter by suction, and dry in air.

(c) *Rotenone-CCl<sub>4</sub> wash soln*.—Sat. CCl<sub>4</sub> at 0°, and keep at 0° during use.

(d) *Alcohol saturated with rotenone at room temp.*

(e) *Charcoal, activated*.—Norit-A neutral, or equiv.

**6.161**

**Preparation of Solution**

(a) Weigh 30 g (if sample contains >7% rotenone, use amt to give 1.0–1.5 g rotenone in 200 mL aliquot) finely powd root and 10 g of the C, (e), into 500 mL g-s erlenmeyer. Add 300 mL CHCl<sub>3</sub>, measured at known room temp.; fasten stopper securely and place flask on shaking machine. Agitate vigorously ≥4 hr, preferably interrupting shaking with overnight rest (or flask may be shaken continuously overnight). Rapidly filter mixt. into suitable flask, using fluted paper without suction and keeping funnel covered with watch glass to avoid evapn loss. Stopper flask and adjust temp. of filtrate to that of original CHCl<sub>3</sub>.

(b) *Alternative extraction method*.—If sample has ratio of rotenone to total ext of >0.4, use amt contg 1.0–1.5 g rotenone and successively ext 4 times with CHCl<sub>3</sub>, using 300 mL CHCl<sub>3</sub> and 4 hr agitation for first extn as in (a) and 200 mL and 2 hr each for other extns. Filter after each extn and return marc to flask for extn with fresh solv. Finally combine exts, evap. almost to dryness, and use entire ext to det. rotenone.

(c) *Extraction method for formulations containing 0.75–1.0% rotenone with or without sulfur and/or pyrethrins*.—Weigh two 50 g portions sample into sep. 500 mL g-s erlenmeyers. Add 5 g of the C and 300 mL CHCl<sub>3</sub>, measured at known room temp., to each. Stopper and continue as in (a).

**6.162****Determination**

(Caution: See 51.011, 51.018, 51.046, 51.049, and 51.056.)

Pipet 200 mL soln, 6.161 (or entire soln if alternative extn, (b), is used), into 500 mL Pyrex erlenmeyer and distil until ca 25 mL remains. (For formulations, 6.161(c): In absence of S, combine the 2 exts in one of the erlenmeyers. In presence of S, remove all  $\text{CHCl}_3$  on steam bath in air current, avoiding prolonged heating. Add 35 mL acetone to each residue and boil gently on steam bath to dissolve all resins. Remove from steam bath, stopper tightly, and hold 2 hr at 0–5°. Filter both acetone solns thru same 15 mL, medium porosity, fritted glass buchner into single 500 mL erlenmeyer. Rinse and wash with acetone at 5°. Remove acetone as  $\text{CHCl}_3$  was removed above.)

Evap. almost to dryness on steam bath in current of air. Remove remainder of solv. under reduced pressure, heating cautiously on steam bath when necessary to hasten evapn. (Suction may be applied directly to flask if stopper with vent is used to release pressure, so that excessive vac. may be avoided. Use flasks with slightly convex bottoms; do not use flasks below av. wt.) Dissolve ext in 15 mL hot  $\text{CCl}_4$  and again, in similar manner, remove all solv. Repeat with another 10–15 mL portion hot  $\text{CCl}_4$ . (This treatment removes all  $\text{CHCl}_3$  from resins.  $\text{CHCl}_3$  ext is usually completely sol. in  $\text{CCl}_4$ ; if small amts of insol. material are present, purification described later will eliminate them.)

Dissolve residue in ca 10 mL  $\text{CCl}_4$  and transfer quant. with hot  $\text{CCl}_4$  to 50 mL erlenmeyer marked at 25 mL. Adjust vol. to 25 mL by evapg on steam bath or by adding  $\text{CCl}_4$ . Cool flask in ice bath several min, stopper flask, and swirl until crystn is apparent. Seed with few crystals of rotenone- $\text{CCl}_4$  solvate if necessary to induce crystn. If at this stage only small amt of cryst. material seps, add accurately weighed amt of purified rotenone, 6.160(a), estd to be enough to assure that final result, expressed as pure rotenone, is  $\geq 1$  g. Then warm to dissolve completely, and again induce crystn. At same time prep. satd soln of rotenone in  $\text{CCl}_4$ , 6.160(c), for washing. Place flasks contg ext and washing soln in ice bath capable of holding temp. at 0°, and let stand overnight. (Store ice bath in refrigerator to keep ice from melting too rapidly.)

After 17–18 hr in ice bath, rapidly filter ext thru weighed gooch fitted with filter paper disk, removing flask from ice bath only long enough to pour each fraction of ext into crucible. Rinse cryst. residue from flask and wash under suction once with the ice-cold satd rotenone- $\text{CCl}_4$  wash soln. ( $\leq 12$ –15 mL soln should be used for rinsing and washing.) Continue suction ca 5 min; then dry to const wt at 40° (ca 1 hr). Wt obtained is crude rotenone- $\text{CCl}_4$  solvate.

Break up contents of crucible with spatula, mix thoroly, and weigh 1.000 g into 50 mL erlenmeyer. Add 10 mL alcohol previously satd with rotenone at room temp., swirl flask few min, stopper tightly, and set aside  $\geq 4$  hr, preferably overnight, at same temp. Filter on weighed gooch fitted with filter paper disk. Rinse crystals from flask and wash under suction with alcohol satd with rotenone at temp. of recrystn (ca 10 mL usually required). Continue suction 3–5 min and then dry crucible at 105° to const wt (ca 1 hr).

Multiply g residue by g total crude rotenone- $\text{CCl}_4$  solvate, and add 0.07 g to product as correction for rotenone held in soln in the 25 mL  $\text{CCl}_4$  used in crystn. If any pure rotenone was added, subtract its wt from value obtained. This gives wt pure rotenone contained in aliquot of ext.

*Note:* Most important precaution in using this method is to keep temp. of  $\text{CCl}_4$ -rotenone wash soln and crucibles as near 0° as possible. Keep wash soln surrounded by crushed ice except when actually being used. In warm weather keep crucibles in refrigerator until ready to use.

**Infrared Method (47)—Official First Action**

(Not applicable to derris products)

**6.163****Standardization**

Prep. std solns of purified rotenone, 6.160(a), in  $\text{CHCl}_3$  at concns of 5, 10, 15, and 20 mg/mL. Scan each std soln from 7.0 to 8.0  $\mu\text{m}$  at speed of 6 min/ $\mu\text{m}$  and scale of 10 cm/ $\mu\text{m}$ , using 0.1 mm cell and accurately matching cell filled with  $\text{CHCl}_3$  as ref. Scan each in duplicate. Obtain av. *A* of each concn, using 7.57  $\mu\text{m}$  as base point and 7.65  $\mu\text{m}$  as peak. Plot *A* against concn.

**6.164****Determination**

Weigh sample contg 250–300 mg rotenone into 25 × 200 mm culture tube. Add 1–2 g anhyd.  $\text{Na}_2\text{SO}_4$ , 2 g activated charcoal, and 50 mL  $\text{CHCl}_3$  by pipet. Close securely with Teflon-lined screw cap and tumble end over end 1 hr at ca 35 rpm. Filter thru medium paper, avoiding evapn losses. Transfer 20 mL aliquot to 50 mL erlenmeyer and evap. on steam bath with current of air. Transfer residue to 10 mL g-s vol. flask and dil. to vol. with  $\text{CHCl}_3$ . Stopper, and mix thoroly.

Scan from 7.0 to 8.0  $\mu\text{m}$ , using 0.1 mm cell and matched cell filled with  $\text{CHCl}_3$  as ref. Det. *A* by baseline method from 7.57 to 7.75  $\mu\text{m}$  and peak at 7.65  $\mu\text{m}$ , using same scanning speed and scale expansion as in stdzn.

Calc. % rotenone from std curve and wt sample in final diln.

**6.165 Total Ether Extract—Official Final Action**

(Caution: See 51.009, 51.039, 51.054, and 51.070(b).)

Ext 5 g finely powd root with ether 48 hr in Soxhlet or other efficient extn app. Conc. ext and filter off any insol. material present. Receive filtrate in tared beaker, evap. ether on steam bath, and dry in oven at 105° to const wt.

**Piperonyl Butoxide (48)—Official Final Action****6.166****Apparatus and Reagents**

(a) *Photoelectric colorimeter*.—Equipped with narrow band-pass interference type filter with central wavelength 630 nm. (Filter is available from: Baird-Atomic Inc.; Bausch and Lomb Optical Co., 10 Champeney Terrace, Rochester, NY 14602; and Photovolt Corp., 1115 Broadway, New York, NY 10010.) Spectrophtr set at wavelength in range 625–635 nm may also be used.

(b) *Purified tannic acid*.—Purify as follows: To 20 g tannic acid (USP reagent grade) add 100 mL EtOAc (99%) and stir mech. ca 1 hr. Filter by suction thru fritted glass funnel, and wash residue with three 5 mL portions EtOAc. To combined filtrate and washings add 2 g finely powd Darco G-60 (or equiv. decolorizing C), and stir mech. ca 0.5 hr. Filter by gravity thru double thickness Whatman No. 1, or equiv., paper into graduated dropping funnel. Wash residue several times with EtOAc until vol. filtrate and washings is ca 125 mL. Place dropping funnel over 1 L, 3-neck, r-b flask, equipped with mech. stirrer, and with vigorous agitation in flask, add filtrate dropwise to 5 times its vol. of toluene. Purified tannic acid is pptd immediately.

Filter by suction thru fritted glass funnel, and wash product thoroly with toluene, stirring solids with toluene to assure complete removal of EtOAc. Continue suction until practically all toluene is removed. Dry purified tannic acid in vac. oven at ca 40°, and place in tightly stoppered bottle.

(c) *Tannic acid reagent*.—Completely dissolve exactly 0.025 g purified tannic acid in 20 mL HOAc by shaking at room temp. Add 80 mL  $\text{H}_3\text{PO}_4$  and mix thoroly. Prep. fresh daily. Store tightly stoppered, as it is hygroscopic.

(d) *Purified piperonyl butoxide*.—Purify by low pressure fractional distn of tech. product. (Caution: See 51.015.) Also available from Fairfield American Corp., 3932 Salt Rd, Medina, NY 14103.

(e) *Piperonyl butoxide std soln*.—50 µg/0.1 mL. Weigh exactly 1.000 g purified piperonyl butoxide into 100 mL vol. flask. (Hypodermic syringe and needle are convenient for adding compd to flask.) Dil. to vol. with deodorized kerosene and mix well. Pipet 10 mL of this soln into 200 mL vol. flask. Dil. to vol. with deodorized kerosene and mix well. This soln is stable for several months. If std is to be used with sample contg pyrethrum, add enough pyrethrum ext to std before initial diln to give ratio piperonyl butoxide to pyrethrins similar to sample.

## 6.167

*Preparation of Sample*

Accurately weigh sample contg 0.5–1.5 g piperonyl butoxide into tared 100 mL vol. flask, dil. to vol. with deodorized kerosene, and mix well. Pipet 10 mL into 200 mL vol. flask, dil. to vol. with deodorized kerosene, and mix well.

## 6.168

*Determination*

Pipet 0.1 mL (from 1 mL pipet graduated in 0.1 mL) sample soln into 18 × 150 mm test tube. Add exactly 5 mL tannic acid reagent and shake vigorously 1 min. Treat std and blank, consisting of 0.1 mL deodorized kerosene, simultaneously in same manner.

Place test tubes in test-tube basket and place in vigorously boiling H<sub>2</sub>O bath 5 min. Remove basket and let tubes cool to room temp. Transfer solns to colorimeter tubes and read, against H<sub>2</sub>O, using 625–635 nm filter or setting. (After cooling to room temp. there is no appreciable change in A for several hr.)

Subtract A<sub>0</sub> of deodorized kerosene from readings of both sample, A, and std, A'.

$$\text{mg Piperonyl butoxide} = A \times 0.05/A'$$

## PYRETHRINS

*Mercury Reduction Method (49)—Official Final Action*

(Caution: See 51.039, 51.054, 51.070, and 51.073.)

## 6.169

*Reagents*

(a) *Deniges reagent*.—Mix 5 g yellow HgO with 40 mL H<sub>2</sub>O, and, while stirring, slowly add 20 mL H<sub>2</sub>SO<sub>4</sub>; then add addnl 40 mL H<sub>2</sub>O and stir until all dissolves. Test for absence of mercurous Hg by adding few drops of (b) to 10 mL and titrg with (c) as in 6.171, par. 2, beginning "Add 50 mL previously prepd and cooled dil. HCl . . ."

(b) *Iodine monochloride soln*.—Dissolve 10 g KI and 6.44 g KIO<sub>3</sub> in 75 mL H<sub>2</sub>O in g-s bottle; add 75 mL HCl and 5 mL CHCl<sub>3</sub>, and adjust to faint I color (in CHCl<sub>3</sub>) by adding dil. KI or KIO<sub>3</sub> soln. If much I is liberated, use stronger soln of KIO<sub>3</sub> than 0.01M at first, making final adjustment with 0.01M soln. Keep in dark and readjust when necessary. Do not store in refrigerator.

(c) *Potassium iodate std soln*.—0.01M. Dissolve 2.14 g pure KIO<sub>3</sub>, previously dried at 105°, in H<sub>2</sub>O and dil. to 1 L. 1 mL = 0.0057 g pyrethrin I and needs no further stdzn.

(d) *Alcoholic sodium hydroxide soln*.—(1) 1.0N.—Dissolve 40 g NaOH in alcohol and dil. to 1 L with alcohol. (2) 0.5N.—Dil. 1.0N with alcohol (1+1).

(e) *Petroleum ether*.—Aromatic-free, bp range 30–60°.

(f) *Ethyl ether*.—Peroxide-free, reagent grade.

## 6.170

*Preparation of Sample*

(a) *Pyrethrum powder*.—Ext sample contg 40–150 mg total pyrethrins in Soxhlet or other efficient extn app. 7 hr with pet

ether. After extn is complete, evap. pet ether to ca 40 mL, stopper flask, and place in refrigerator at 0±0.5° overnight. Filter cold ext thru cotton plug satd with cold pet ether, in stem of funnel, collecting filtrate in 250 mL erlenmeyer. Wash with three 15 mL portions cold pet ether. Evap. filtrate and washings on H<sub>2</sub>O bath, using air current, until <1 mL solv. remains.

Add 15–20 mL 0.5N alc. NaOH to evapd ext, connect to reflux condenser, and boil gently 1–1.5 hr. Transfer to 600 mL beaker and add enough H<sub>2</sub>O to bring vol. to 200 mL. Add few glass beads, or preferably use boiling tube, and boil down to 150 mL. Transfer to 250 mL vol. flask and add 1 g Filter-Cel and 10 mL 10% BaCl<sub>2</sub> soln. Do not shake before dilg to vol. Dil. to vol., mix thoroly, filter off 200 mL, neutze with H<sub>2</sub>SO<sub>4</sub> (1+4), using 1 drop phthln, and add 1 mL excess. (If necessary to hold soln overnight at this point, leave in alk. condition.)

(b) *Pyrethrum extracts in mineral oil*.—Weigh or measure sample contg 40–150 mg total pyrethrins, add 50 mL pet ether and 1 g Filter-Cel, and place in refrigerator at 0±0.5° overnight. Filter thru gooch into 300 mL erlenmeyer and wash with three 15 mL portions cold pet ether. Evap. filtrate and washings on H<sub>2</sub>O bath, using air current, until <1 mL solv. remains.

Add 20 mL 1N alc. NaOH, or more if necessary, to ext, connect to reflux condenser, and boil gently 1–1.5 hr. Transfer to 600 mL beaker and add enough H<sub>2</sub>O to make aq. layer 200 mL. If >20 mL alc. NaOH soln was used, add enough H<sub>2</sub>O so that all alcohol is removed when vol. is reduced to 150 mL. Add few glass beads, or preferably use boiling tube, and boil aq. layer down to 150 mL. Transfer to 500 mL separator and drain aq. layer into 250 mL vol. flask. Wash oil layer once with H<sub>2</sub>O and add wash H<sub>2</sub>O to aq. portion. If slight emulsion still persists after draining aq. layer and washings, add 2–3 mL 10% BaCl<sub>2</sub> soln, but do not shake vigorously after adding BaCl<sub>2</sub> because reversed emulsion difficult to sep. may form. To aq. soln in 250 mL flask add 1 g Filter-Cel and ≥10 mL of the BaCl<sub>2</sub> soln. Swirl gently and let stand 30 min. Dil. to vol., mix thoroly, and filter off 200 mL. Test filtrate with BaCl<sub>2</sub> soln to see if enough has been added to obtain clear soln. Neutze with H<sub>2</sub>SO<sub>4</sub> (1+4), using 1 drop phthln, and add 1 mL excess. (If necessary to hold soln overnight at this point, leave in alk. condition.)

## 6.171

*Determination of Pyrethrin I*

Filter acid soln from 6.170(a) or (b) thru 7 cm paper, coated lightly with suspension of Filter-Cel in H<sub>2</sub>O, on buchner, and wash with three 15 mL portions H<sub>2</sub>O. Transfer to 500 mL g-s separator and ext with two 50 mL portions pet ether. Shake each ext ≥1 min, releasing pressure if necessary by inverting separator and carefully venting thru stopcock. Let layers sep. ≥5 min or until aq. layer is clear before draining and re-extn. Reserve aq. layer for pyrethrin II detn. Do not combine pet ether exts but wash each in sequence with same three 10 mL portions H<sub>2</sub>O, and filter pet ether exts thru small cotton plug into clean 250 mL separator. Wash separators and cotton in sequence with 5 mL pet ether. Ext combined pet ether solns with 5 mL 0.1N NaOH, shaking vigorously ≥1 min. Let layers sep. ≥5 min before draining aq. layer into 100 mL beaker. Wash pet ether with addnl 5 mL portion 0.1N NaOH and with 5 mL H<sub>2</sub>O, adding washings to beaker. Add 10 mL Deniges reagent and let stand in complete darkness 1 hr at 25±2°.

Add 20 mL alcohol and ppt HgCl with 3 mL satd NaCl soln. Warm to ca 60° and let stand several min until ppt coagulates and settles. Filter thru small paper, transferring all ppt to paper, and wash with ≥10 mL hot alcohol. Wash with 2 or more 10 mL portions hot CHCl<sub>3</sub> and place paper and contents in 250 mL g-s erlenmeyer. Add 50 mL previously prepd and cooled dil. HCl (3+2). Add 5 mL CHCl<sub>3</sub> or CCl<sub>4</sub> and 1 mL freshly adjusted ICl

soln, and titr. with 0.1*M* KIO<sub>3</sub> soln, shaking vigorously  $\geq 30$  sec after each addn, until no l color remains in CHCl<sub>3</sub> or CCl<sub>4</sub> layer. Take as end point when red color disappears from solv. layer and does not return within 1–3 min. From mL std KIO<sub>3</sub> soln used in titrn and blank on Deniges reagent, calc. % pyrethrin I.

(Reactions:

Addn of ICl does not change vol. relationship between mercurous Hg and KIO<sub>3</sub> soln, and aids in detg end point in titrn of small amts of Hg.)

*Note:* Chrysanthemum monocarboxylic acid reacts with Deniges reagent to form series of colors beginning with phthln red, which gradually changes to purple, then to blue, and finally to bluish green. Color reaction is very distinct with 5 mg monocarboxylic acid, and amts as low as 1 mg can usually be detected. Therefore no pyrethrin I should be reported if color reaction is neg.

With samples contg much perfume or other saponifiable ingredients, it may be necessary to use as much as 50 mL 1*N* alc. NaOH. When lethanes are present, after washing HgCl ppt with alcohol and CHCl<sub>3</sub>, wash once more with alcohol and then several times with hot H<sub>2</sub>O.

#### 6.172

#### Determination of Pyrethrin II (50)

If necessary, filter aq. residue from pet ether extn thru gooch. Conc. filtrate to ca 50 mL and transfer to 500 mL g-s separator. Wash beaker with three 15 mL portions H<sub>2</sub>O. Acidify with 10 mL HCl and sat. with NaCl. (Acidified aq. layer must contain visible NaCl crystals thruout following extns.)

Ext with 50 mL ether, drain aq. layer into second separator, and ext again with 50 mL ether. Continue extg and draining aq. layer, using 35 mL for third and fourth extns. Shake each ext  $\geq 1$  min, releasing pressure, if necessary, by inverting separator and carefully venting thru stopcock. Let layers sep.  $\geq 5$  min or until aq. layer is clear before subsequent draining and extn. Combine ether exts, drain, and wash with three 10 mL portions satd NaCl soln. Filter ether exts thru cotton plug into 500 mL erlenmeyer and wash separator and cotton with addnl 10 mL ether. Evap. ether on H<sub>2</sub>O bath, and remove any fumes of HCl with air current and continued heating  $\leq 5$  min. Dry 10 min at 100°.

(a) *For crude pyrethrum exts.*—Treat residue with 75 mL boiling H<sub>2</sub>O and filter thru 9–11 cm Whatman No. 1, or equiv., paper. Wash flask and paper with five 20 mL portions boiling H<sub>2</sub>O or until filtrate from final wash is neut. to litmus. Add 1–2 drops phthln and rapidly titr. with 0.02*N* NaOH (1 mL = 0.00374 g pyrethrin II). Check normality of 0.02*N* NaOH same day sample is titrd.

(b) *For refined pyrethrum exts.*—Add 2 mL neut. alcohol and 20 mL H<sub>2</sub>O, and heat to dissolve acid. Cool, filter thru gooch if necessary, add 1–2 drops phthln, and titr. with 0.02*N* NaOH (1 mL = 0.00374 g pyrethrin II). Check normality of 0.02*N* NaOH same day as sample is titrd.

#### Sabadilla Alkaloids (51)—Official Final Action

(In dust formulations)

#### 6.173

#### Determination

(Caution: See 51.011, 51.040, and 51.056.)

Weigh 10 g mixed 50% sabadilla dust (or corresponding amt of lesser concn) into 500 mL g-s erlenmeyer. Add exactly 300 mL ether-CHCl<sub>3</sub> (3+1), and shake 5 min. Make alk. with 10 mL NH<sub>4</sub>OH and shake mech. 2 hr. Let stand overnight; then shake 1 hr.

Filter, avoiding evapn. Place 200 mL aliquot in 500 mL separator, acidify with H<sub>2</sub>SO<sub>4</sub> (3+97), and shake; withdraw small amt aq. layer and test with litmus paper, returning soln to separator. Add 50 mL of the dil. H<sub>2</sub>SO<sub>4</sub> and shake. Let sep. and transfer acid ext to second 500 mL separator. Add 50 mL pet ether to acid ext and shake. Let layers sep. and transfer acid ext to third separator. Repeat extn of soln in first separator with two 50 mL portions of the dil. H<sub>2</sub>SO<sub>4</sub>, using same 50 mL pet ether in second separator for washing. Collect acid exts in third separator.

Make acid exts alk. to phthln with NH<sub>4</sub>OH. Ext with three 50 mL portions CHCl<sub>3</sub>. Wash each CHCl<sub>3</sub> ext by shaking gently with same 100 mL portion H<sub>2</sub>O in fourth separator. (If emulsion forms, add small amt anhyd. Na<sub>2</sub>SO<sub>4</sub>.)

Filter each CHCl<sub>3</sub> ext thru cotton into weighed 250 mL flask. Evap. CHCl<sub>3</sub> on steam bath. Add few mL alcohol, and evap. again. Dry 1 hr at 100° and weigh sabadilla alkaloids. Calc. % total alkaloids.

#### 6.174

#### Qualitative Test

Add 1–2 mL H<sub>2</sub>SO<sub>4</sub> to few mg of residue, 6.173. Presence of sabadilla alkaloids is indicated by yellow that gradually becomes intensely red with greenish fluorescence.

### TOBACCO AND TOBACCO PRODUCTS

#### Nicotine

(*Note:* Nicotine is very toxic. Avoid contact with skin.)

#### Silicotungstic Acid Method (52)—Official Final Action

(Includes nornicotine)

#### 6.175

#### Reagent

*Silicotungstic acid soln.*—Dissolve 120 g silicotungstic acid (4H<sub>2</sub>O.SiO<sub>2</sub>.12WO<sub>3</sub>.22H<sub>2</sub>O or SiO<sub>2</sub>.12WO<sub>3</sub>.26H<sub>2</sub>O) in H<sub>2</sub>O and dil. to 1 L. (Acid should be white or pale yellow crystals, free from green color; soln should be free from cloudiness and green color. Of the several silicotungstic acids, 4H<sub>2</sub>O.SiO<sub>2</sub>.10WO<sub>3</sub>.3H<sub>2</sub>O and 4H<sub>2</sub>O.SiO<sub>2</sub>.12WO<sub>3</sub>.20H<sub>2</sub>O do not give cryst. ppts with nicotine and should not be used.)

#### 6.176

#### Determination

Weigh sample contg preferably 0.1–1.0 g nicotine. If sample contains very little nicotine (ca 0.1%), do not increase amt to point where it interferes with distn. Wash with H<sub>2</sub>O into 500 mL Kjeldahl flask, and if necessary add little paraffin to prevent frothing and few small pieces pumice to prevent bumping. Add 10 g NaCl and 10 mL *NaOH soln* (30% by wt), and close flask with rubber stopper thru which passes stem of trap bulb and inlet tube for steam. Connect trap bulb to well-cooled condenser, lower end of which dips below surface of 10 mL HCl (1+4) in suitable receiving flask. Steam distil rapidly. When distn is well under way, heat flask to reduce vol. of liq. as far as practicable without bumping or excessive sepn of insol. matter. Distil until few mL distillate shows no cloud or opalescence when treated with drop silicotungstic acid soln and drop HCl (1+4). Confirm alky of residue in distn flask with phthln.

Adjust distillate, which may total 1.0–1.5 L, to convenient exact vol. (soln may be concd on steam bath without loss of nicotine), mix well, and pass thru dry filter if not clear. Test distillate with Me orange to confirm acidity. Pipet aliquot contg ca 0.1 g nicotine into beaker. (If samples contain very small amts of nicotine, aliquot contg as little as 0.01 g nicotine may be used.) To each 100 mL liq., add 3 mL HCl (1+4) and 1 mL silicotungstic acid for each 0.01 g nicotine supposed to be

present. Stir thoroly and let stand overnight at room temp. Before filtering, stir ppt to see that it settles quickly and is in cryst. form. Filter on either ashless paper or gooch and wash with HCl (1+1000) at room temp. Continue washing for 2 or 3 fillings of filter after no more opalescence appears when few mL fresh filtrate is tested with few drops nicotine distillate. With paper, transfer paper and ppt to weighed Pt crucible, dry carefully, and ignite until all C is destroyed. Finally heat over Meker burner  $\leq 10$  min. Wt residue  $\times 0.1141$  = wt nicotine in aliquot. With gooch, dry in oven 3 hr at  $105^\circ$  and weigh. Wt residue  $\times 0.1012$  = wt nicotine in aliquot.

## HALOGENATED PESTICIDES

### Aldrin, Dieldrin, and Endrin—Official Final Action

#### ★ Total Chlorine by Sodium Biphenyl ★ Reduction Method (53)

#### 6.177

#### Principle

Org. halogen compds are decomposed by Na biphenyl and liberated halide ion is titrd by Volhard method or potentiometrically after extn with  $H_2O$  from reaction medium. Applicable to detn of aldrin, dieldrin, or endrin in dusts, granules, wettable powders, emulsifiable concs, and solns in absence of other org. Cl-contg compds. More than trace amts of  $H_2O$  and appreciable amts of org. compds contg labile H cause excessive consumption of Na biphenyl. Interference of S is avoided, when present, by special treatment.

#### 6.178

#### Reagents

(a) *Dilute nitric acid*.—6% by wt. Add 60 mL  $HNO_3$  to 945 mL  $H_2O$ .

(b) *Sodium biphenyl reagent*.—30% w/w. (Caution: See 51.034 and 51.038.) Place 300 mL dry toluene and 58 g Na in dry 2 L 3-neck flask equipped with adjustable speed sealed stirrer, inlet for N, and reflux condenser. With stirrer off, and with slow stream of N passing thru flask, warm until refluxing begins and Na is entirely melted. Agitate vigorously until Na is finely dispersed; then cool to  $<10^\circ$ . Remove reflux condenser and add 1.25 L anhyd. ethylene glycol dimethyl ether. Add 390 g biphenyl with moderate stirring and with slow stream of N passing thru flask. Reaction should begin within few min, indicated by blue or green color which gradually darkens to black. Maintain temp. at  $<30^\circ$  with oil bath or other cooling medium not involving hazard should flask contg Na break. Reaction should be complete in 1 hr. Reagent protected from moisture and air has useful life of 1–2 months at  $25^\circ$ .

(Premixed reagent, packed in 15 mL vials, each enough for 1 detn, is available from Southwestern Analytical Chemicals, Inc., PO Box 485, Austin, TX 78767.)

(c) *Toluene*.—Nitration grade, Cl-free.

#### 6.179

#### Preparation of Sample

(Caution: See 51.041 and 51.084.)

(a) *Technical products*.—Accurately weigh ca 0.1 g sample into 125 mL separator contg 25–30 mL toluene. Cautiously add 10–14 g Na biphenyl reagent, mix by swirling, and let stand 5 min. If soln is not dark green, add addnl 10–14 g reagent. (Dieldrin and endrin require 15 min reaction time after final addn of reagent.)

Destroy excess reagent by dropwise addn of  $H_2O$ , shaking frequently between addns, until green color is completely removed. Then slowly add 25 mL dil.  $HNO_3$ , with intermittent swirling. Stopper separator, and mix with gentle rocking motion,

venting occasionally. Avoid vigorous shaking during this first extn.

Let sep., rinse stopper and walls of separator with  $H_2O$ , and drain aq. phase into 250 mL g-s erlenmeyer. Re-ext reaction mixt. with two 25 mL portions dil.  $HNO_3$ , shaking vigorously. Add aq. exts to erlenmeyer and det. Cl.

(b) *Emulsifiable concentrates and oil spray solns*.—Mix thoroly and weigh sample contg 0.05–0.08 g Cl into 250 mL separator contg 25–30 mL toluene. Proceed as in (a), beginning "Cautiously add . . ."

(c) *Dusts, granules, and wettable powders*.—Weigh sample contg 0.1–0.15 g active ingredient in paper Soxhlet extn thimble, place in extn app., and ext with ca 150 mL acetone in 300 mL flask 3 hr. Evap. ext to dryness on steam bath, dissolve residue in few mL toluene, and quant. transfer to 250 mL separator, using 25–30 mL toluene. Continue as in (a), beginning "Cautiously add . . ."

If S is brought into soln by decomposition of emulsifiers or other compds such as org. thiophosphates, remove as follows: Add 30% NaOH soln to acid soln in erlenmeyer until alk. to phthln, and add 1 mL excess. Add 5 mL 30%  $H_2O_2$ , heat to bp on hot plate, and boil ca 10 min. Let cool slightly, cautiously add 5 mL more 30%  $H_2O_2$ , and boil again ca 10 min. Cool, and add small flake (ca 0.05 g) *hydrazine sulfate* to remove last traces of  $H_2O_2$ . Neutze with dil.  $HNO_3$  to phthln and add 2–3 mL excess.

#### 6.180

#### Determination

(a) *Colorless solns*.—To acid aq. soln add 30 mL  $H_2O$ , 10 mL nitrobenzene, 3 mL ferric indicator, 6.019(e), and, from buret, 0.4–0.6 mL 0.05N KSCN. Swirling constantly, titr. with 0.1N  $AgNO_3$  until red is discharged, and add 2–5 mL excess. Stopper flask tightly and shake vigorously 15 sec. Without refilling buret, titr. slowly with the 0.05N KSCN until end point approaches. Stopper flask, shake vigorously 20–30 sec, and continue titrn until 1 drop produces distinct reddish color which does not fade on swirling or vigorous shaking.

(b) *Colored solns or chloride in presence of bromide and/or iodide*.—To acid aq. soln add 30 mL  $H_2O$ , transfer to 400 mL beaker, adjust vol. to 200–250 mL, and add 0.5 g  $Ba(NO_3)_2$ . Titr. with 0.1N  $AgNO_3$  potentiometrically, with stirring, using cell system of either glass ref. electrode and Ag indicating electrode or Ag-AgCl electrode system, electronic voltmeter, and 10 mL buret.

(c) *Blank determination*.—Det. blank on all reagents by adding 10–14 g Na biphenyl reagent to 25 mL toluene and continuing as in 6.179(a).

#### 6.181

#### Calculations

% Aldrin, dieldrin, or endrin = (net mL  $AgNO_3$  – mL blank)  $\times$  normality  $\times 35.45 \times F / (10 \times g \text{ sample})$ , where  $F$  is 1.61 for aldrin, 1.81 for dieldrin, and 1.74 for endrin. Net mL  $AgNO_3$  = [mL 0.1N  $AgNO_3$  – (mL 0.05N KSCN/2)].

(For most accurate results, det. factor  $F$  for specific batch of tech. pesticide used in formulation. Toxicant content is stenciled on drum. Calc.  $F = P/C$ , where  $P$  = % purity (toxicant content as stenciled on drum), and  $C$  = % Cl by wt.)

#### Infrared Method (53)

#### 6.182

#### Principle

Dieldrin and endrin in dusts, granules, wettable powders, emulsifiable concs, and solns are purified on adsorbent columns. Hexachloro-epoxy-octahydro-endo,exo-dimethanonaphthalene

★ Surplus method—see inside front cover.

(HEOD) content of the purified dieldrin or of tech. dieldrin is detd by IR, using baseline technic, and dieldrin is calcd assuming 85% HEOD content. Endrin content of purified or tech. endrin is detd as hexachloro-epoxy-octa-hydro-endo,endo-dimethanonaphthalene similarly.

Aldrin is extd from dusts, wettable powders, and inorg. fertilizers on adsorbent column. Hexachloro-hexahydro-endo,exo-dimethanonaphthalene (HHDN) content of the ext or of tech. aldrin is detd by IR, using baseline technic, and aldrin is calcd assuming 95% HHDN content. Method is not applicable to emulsifiable concs or granules contg petroleum hydrocarbon solvs or to mixts contg other common pesticides or adjuvants that absorb in same wavelength region as HHDN.

**6.183****Reagents and Apparatus**

(a) *Chromatographic solvent A.*—Mix 1 vol.  $\text{CHCl}_3$  with 19 vols hexane.

(b) *Chromatographic solvent B.*—Mix 1.5 vols acetone with 98.5 vols chromatgc solvent A.

(c) *Extraction solvent.*—Mix 1 vol. acetone with 19 vols  $\text{CS}_2$ .

(d) *Infrared spectrophotometer.*—With sealed liq. cells with NaCl windows, having optical path length of ca 0.1 mm (dieldrin and endrin) and 0.2 mm (aldrin).

**6.184****Preparation of Standard Solutions**

(a) *HEOD std soln for dieldrin.*—Accurately weigh ca 100, 200, 300, 400, 500, and 600 mg std hexachloro-epoxy-octahydro-endo,exo-dimethanonaphthalene (HEOD) into 10 mL vol. flasks, dissolve in  $\text{CS}_2$ , and dil. to vol. Concn will be 1, 2, 3, 4, 5, and 6 g/100 mL, resp.

(b) *Std soln for endrin.*—Accurately weigh ca 50, 100, 150, 200, 300, and 400 mg std hexachloro-epoxy-octahydro-endo,endo-dimethanonaphthalene (endrin) into 10 mL vol. flasks, dissolve in  $\text{CS}_2$ , and dil. to vol. Concn will be 0.5, 1.0, 1.5, 2.0, 3.0, and 4.0 g/100 mL, resp.

(c) *HHDN std soln for aldrin.*—Accurately weigh ca 100, 150, 200, 250, 300, and 350 mg std hexachloro-hexahydro-endo,exo-dimethanonaphthalene (HHDN) into 10 mL vol. flasks, dissolve in  $\text{CS}_2$ , and dil. to vol. Concn will be 1.0, 1.5, 2.0, 2.5, 3.0, and 3.5 g/100 mL, resp.

**6.185****Preparation of Standard Curve**

Fill 0.1 mm cell (0.2 mm for aldrin) with most dil. of stds solns, using hypodermic syringe. Adjust spectrophtr to optimum settings for gain, slit width, response, speed, and drum drive. Make duplicate scans of  $\text{CS}_2$  soln over scanning range indicated in Table 6:01 and repeat with each of other std solns at same instrument settings.

For each of scans of the 6 std solns of each compd, draw line between baseline points indicated in table. Draw perpendicular from zero radiation line thru absorption peak to baseline and measure distance from 0 line to peak,  $P$ , and to baseline  $P_0$ . Calc.  $A (= \log P_0/P)$  and plot as ordinate against concn in g/100 mL as abscissa.

Since std curve intersects abscissa at pos. concn value, method is not applicable to concns below this value.

Peak wavelengths given in table are characteristic for low

**Table 6:01 Characteristic Wavelength Points for Infrared Determination of Dieldrin, Endrin, and Aldrin,  $\mu\text{m}$**

Compound	Scanning Range	Baseline Points	Peak at Low Concn
HEOD	11.59–12.18	11.64, 12.18	11.80
Endrin	11.43–12.04	11.50, 11.97	11.76
HHDN	11.79–12.24	11.85, 12.24	12.01

concn and they shift at higher concns.  $P$  is always detd as distance from 0 line to point of max. absorption.

**6.186****Preparation of Sample**

(Caution: See 51.011, 51.041, 51.046, 51.056, and 51.061.)

(a) *Dusts and wettable powders.*—Transfer 3–20 g sample, depending on concn (75–0.5%), weighed to nearest 0.01 g, to chromatgc tube contg 25–50 mm (ca 5.5 g) Hyflo Super-Cel. (For finely divided dieldrin or endrin powder, use 3 g activated C instead of Super-Cel.) Tamp or vibrate column slightly to settle contents. Place 250 mL wide-mouth erlenmeyer or 500 mL evapg dish under tip of column.

Working in well ventilated hood, add 50 mL portions extn solv. to column (if S is present, ext with acetone instead of extn solv.), letting solv. percolate thru column between addns, until 150 mL ext collects. Rinse tip of column with addnl 10 mL extn solv.

Evap. solv. almost to dryness on steam bath under N. Dry HEOD or HHDN residues 15 min at 75°; dry endrin in vac. oven 15 min at 30° and 10 mm pressure. (Extd endrin may no longer be associated with its inhibitors. Residue must not be exposed to elevated temps and must be dissolved promptly to avoid decomposition.)

Cool residue and dissolve in few mL  $\text{CS}_2$ . Quant. transfer to vol. flask of such size (5–100 mL) as to give optimum concn of 3 g HEOD, 2 g endrin, or 2 g HHDN/100 mL, dil. to vol. with  $\text{CS}_2$ , and mix thoroly. If soln is cloudy from  $\text{H}_2\text{O}$ , add little NaCl, shake, and let settle.

(b) *Granules containing dieldrin or endrin.*—Slurry 40 g Florisil in 200 mL beaker with 100 mL hexane. Transfer to chromatgc column with stream of hexane from wash bottle. Eliminate any bubbles or voids by vibration or agitation. Let hexane drain until only 2–3 mm layer remains above surface of column. Add small layer of  $\text{Na}_2\text{SO}_4$  to top of column.

Transfer 2–10 g finely ground sample, depending on concn (10–1%), to prepd column. Rinse down column walls with three 10 mL portions chromatgc solv. A, letting each portion enter column before adding next. Add 170 mL chromatgc solv. A, let percolate thru column, and discard.

Gently flow 10 mL chromatgc solv. B down walls of tube, avoiding disturbing surface of adsorbent. After solv. sinks into column, repeat washing with 2 addnl 10 mL portions. Add 220 mL chromatgc solv. B and let flow at rate of 2–5 mL/min, collecting eluate in 500 mL wide-mouth erlenmeyer or evapg dish. Evap. solv. to dryness on steam bath, avoiding spattering, and proceed as in (a), using 5–10 mL vol. flask.

(c) *Emulsifiable concentrates and solns.*—Weigh 1.5 g dieldrin conc. (1.5 lb/gal.), 1.0 g endrin conc. (1.6 lb/gal.), or 30.0 g 0.5% dieldrin soln, and add 5 mL hexane. Transfer to prepd column and proceed as in (b).

(d) *Technical materials.*—Transfer sample contg 1.75–4.00 g dieldrin, 1.50–3.00 g endrin, or 1.00–2.00 g aldrin, weighed to 0.01 g, to 100 mL vol. flask. Dissolve in  $\text{CS}_2$  and dil. to vol. with  $\text{CS}_2$ .

**6.187****Determination**

Fill same 0.1 mm cell (0.2 mm for aldrin) used for prepn of std curve with sample soln. Make duplicate scans, and calc.  $A$  and mean  $A$  as in prepn of std curve. From appropriate std curve, obtain g HEOD, endrin, or HHDN/100 mL sample soln,  $W$ .

$$\% \text{ dieldrin} = W \times V \times 1.175/S;$$

$$\% \text{ endrin} = W \times V/S;$$

$$\% \text{ aldrin} = W \times V \times 1.053/S;$$

where  $V$  = mL sample soln;  $S$  = g sample; 1.175 and 1.053 = conversion factors HEOD to dieldrin and HHDN to aldrin, resp.

**Amiben (3-Amino-2,5-dichlorobenzoic Acid) (54)—Official Final Action**

**AOAC-CIPAC Method**

**6.188**

**Principle**

Amiben contains conjugated  $\pi$  electron system of benzene which absorbs strongly in UV. Absorption is measured quant. at 297 nm. (*Caution: See 51.018 and 51.041.*)

**6.189**

**Apparatus and Reagents**

- (a) *Spectrophotometer*.—For use in UV, with 1 cm cells.  
 (b) *Shake-out flask*.—250 mL erlenmeyer, with screw cap.  
 (c) *Amiben std solns.*—(1) *Stock soln.*—0.38 mg/mL. Accurately weigh  $19 \pm 2$  mg amiben (Amchem Products, Inc., Ambler, PA 19002) into 50 mL vol. flask, add 25 mL 1% NaOH, agitate until dissolved, dil. to vol., and mix. (2) *Working soln.*—0.038 mg/mL. Pipet 5 mL stock soln into 50 mL vol. flask, dil. to vol. with 1% NaOH soln, and mix.

**6.190**

**Preparation of Sample**

Mix 10 g granular sample on  $12 \times 12$ " paper by lifting alternate corners.

**6.191**

**Determination**

- (a) *Dry granular formulations*.—Add amt solid material and 1% NaOH soln specified in Table 6:02 to 250 mL shake-out flask and shake 30 min. Filter, and transfer stated aliquot to vol. flask. Dil. to vol. with 1% NaOH soln and mix. Det.  $A$  at 360 and 297 nm against 1% NaOH. Calc.  $\Delta A = A_{297} - A_{360}$ . Det.  $\Delta A'$  of working std soln similarly.

% Amiben =  $(\Delta A \times (\text{mg std/mL}) \times F) / (\Delta A' \times \text{g sample} \times 10)$ , where  $F$  = factor in Table 6:02.

- (b) *Liquid formulations*.—Weigh amt liq. indicated in Table 6:02 into 100 mL vol. flask, dil. to vol. with 1% NaOH soln, and mix. Transfer 1 mL aliquot to 100 mL vol. flask, dil. to vol. with 1% NaOH, and mix. Proceed as in (a).

**Benzene Hexachloride (BHC) (Hexachlorocyclohexane)  
Gamma Isomer (Lindane)**

**Partition Chromatographic Method (55)  
Official Final Action**

(*Caution: See 51.009, 51.011, 51.039, 51.040, 51.041, and 51.054.*)

**6.192**

**Apparatus**

- (a) *Partition column*.—Column and O type reduction valve are shown in Fig. 6:04. Construct column of heavy-wall Pyrex tubing ca 3.5 mm thick, 90 cm long  $\times$  2.5 cm diam. Seal coarse porosity fritted glass disk in place and attach No. 18/9  $\frac{1}{8}$  joint 5 cm below disk. Supply pressure from laboratory supply line. (Column available from SGA Scientific, Inc.; specify Cat. No. JC 1800 constructed from heavy rather than std wall tubing.)

- (b) *Solvent evaporator*.—Fig. 6:04. Evap. fractions to dryness

under reduced pressure at 60°, with aid of H<sub>2</sub>O pump. Recover solv. in trap consisting of Kjeldahl flask immersed in mixt. of NaCl and ice.

- (c) *Melting point apparatus*.—Use Thiele mp app. equipped with mech. stirrer. App. shown in Fig. 6:05, or Hershberg modification (56) (available from Ace Glass, Inc., Cat. No. 7686) is suitable.

- (d) *Thermometer*.—Precision grade, meeting NBS specifications: partial immersion; range 90–120° in 0.2° subdivisions. Calibrated by NBS or against thermometer checked by NBS.

- (e) *Melting point tubes*.—1–2 mm capillary tubes of uniform wall thickness and diam.

**6.193**

**Reagents**

- (a) *n-Hexane*.—Com. grade, distd before use.  
 (b) *Nitromethane*.—Reflux com. grade material 4 hr and distil. No visible residue is left after evapn of 10 mL purified material.  
 (c) *Silicic acid*.—Use Mallinckrodt reagent grade (for chromatgy) which meets following requirements: When column prep'd as in 6.195 is used for detn on sample contg known amt of  $\gamma$ -isomer, flow rate and packing characteristics should be similar to those of an H<sub>2</sub>SiO<sub>3</sub> known to be satisfactory, and recovery of  $\gamma$ -BHC should be within  $\pm 3\%$  of the  $\gamma$ -BHC content.  
 (d) *Dye soln*.—Dissolve 25 mg D&C Violet No. 2 (1-hydroxy-4-*p*-toluidino-anthraquinone) in 50 mL mobile solv. and store in g-s bottle. (Available from Aldrich Chemical Co.)  
 (e) *Mobile solvent*.—Satd soln nitromethane in *n*-hexane. Vigorously shake 2 L *n*-hexane with excess nitromethane in g-s bottle. Decant mobile solvent from nitromethane as needed.

**6.194**

**Preparation of Sample**

- (a) *Powders containing more than 10%  $\gamma$ -BHC*.—Crush and thoroly mix sample with mortar and pestle. Weigh enough sample into tared 125 mL erlenmeyer to provide ca 0.2 g  $\gamma$ -isomer after extg and aliquoting. Add 25 mL mobile solv., heat just to bp on steam bath, and cool to room temp., shaking occasionally. Decant ext thru buchner with ca 34 mm medium porosity fritted disk into 100 mL Kohlrausch flask, with gentle suction. Re-ext residue in flask, using 10 mL mobile solv. Wash residue and flask with five 10 mL portions cold mobile solv., decanting each wash thru buchner. Add 2 mL dye soln and dil. to vol. with mobile solv.

- (b) *Dusts containing less than 10%  $\gamma$ -BHC*.—Weigh enough sample to provide 1.75–2.00 g  $\gamma$ -isomer. Transfer to Soxhlet extractor and ext overnight with ether. Evap. most of ether on steam bath and evap. remainder at room temp. under vac. Ext  $\gamma$ -isomer from residue with mobile solv. as in (a).

**6.195**

**Preparation of Column**

(*Caution: See 51.004 and 51.061.*)

Transfer  $100 \pm 0.5$  g H<sub>2</sub>SiO<sub>3</sub> to high-speed blender, add 300 mL mobile solv., and with mixing, add 55 mL nitromethane. Mix 15–30 sec; then pour into column thru glass funnel. Stir slurry with long glass stirring rod to displace air bubbles. Wash down

**Table 6:02 Parameters for sample analysis**

Sample	Amiben, %	Sample Wt, g $\pm 0.1$	1% NaOH, mL	Aliquot, mL	Final Diln	Factor (F)
Dry granular	1.2	3.0	50	2	50	1,250
Dry granular	4	7.5	100	1	100	10,000
Dry granular	10	3.0	100	1	100	10,000
Liquid	21.6	1.8	100	1	100	10,000

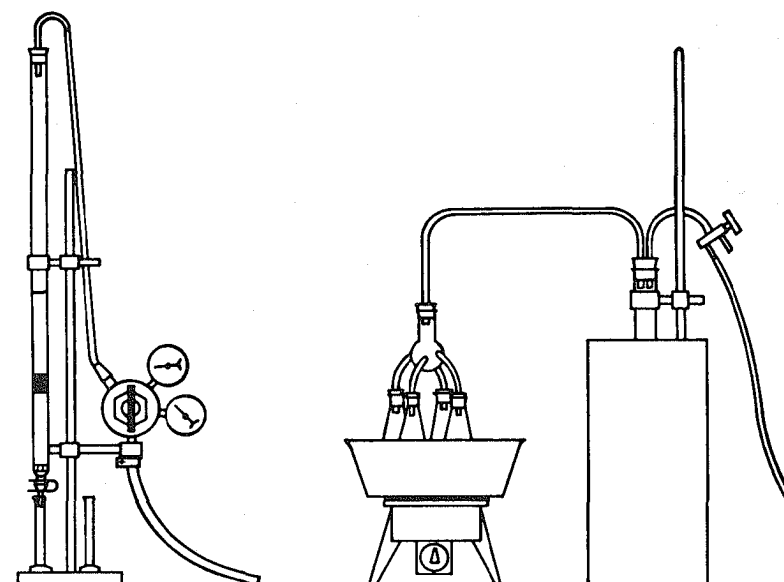

FIG. 6:04—Partition column and solvent evaporator

sides of column with few mL mobile solv. and apply 5 lb pressure to pack column and force out excess solv.; tap column gently to aid packing. When boundary between solv. and  $\text{H}_2\text{SiO}_3$  remains stationary, release pressure cautiously, pipet out most of excess solv., and reapply pressure until ca 3 mm solv. remains above adsorbent.

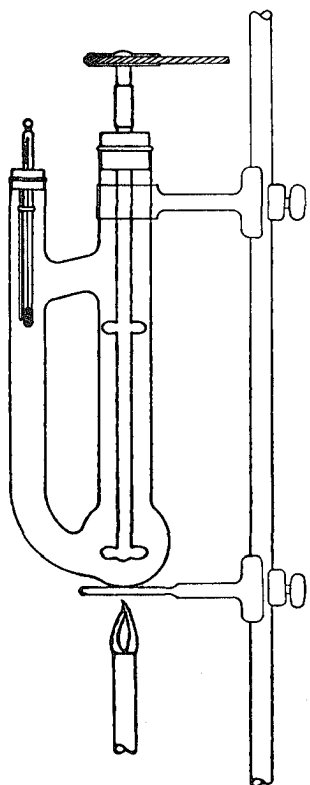

FIG. 6:05—Melting point apparatus

## 6.196

**Determination**

(Caution: See 51.015 and 51.018.)

Pipet 10 mL aliquot of sample soln onto column by letting it flow slowly down inside of column without disturbing  $\text{H}_2\text{SiO}_3$  surface. Wash down side of column with 2 mL mobile solv. and force soln into column by applying 2–3 lb pressure, releasing pressure when all solv. has entered column. Add 10 mL mobile solv. and force into column. Release pressure and slowly add mobile solv. to within 7–12 cm from top of column. Apply enough pressure to force solv. thru column at 3–4 mL/min. Just before last trace of dye leaves column, begin to collect 10 mL fractions, alternately using two 10 mL graduates. Transfer each fraction to 125 mL erlenmeyer and evap. to dryness, using solv. evaporator. (Evap. fractions without boiling; if boiling begins, raise flask momentarily from  $\text{H}_2\text{O}$  bath.)

Appearance of  $\gamma$ -isomer upon evapn is recognized by its tendency to cover bottom of flask as white residual film with typical crystal formation. When first residue of  $\gamma$ -isomer is recognized, begin to collect 10 mL fractions until all  $\gamma$ -isomer is obtained (usually  $\leq 8$  fractions). Dissolve residue in each flask with 5 mL *n*-hexane and transfer to weighed flask, rinsing flasks successively with 5 mL portions *n*-hexane. Evap. solv., using solv. evaporator. Evacuate flask ca 20 min at room temp. with vac. pump. (There is little danger in evacuating 125 mL erlenmeyer; larger size erlenmeyer, however, is likely to collapse under vac.) Release vac., wipe with clean, moist towel, and let stand 5 min. Weigh, and calc. %  $\gamma$ -benzene hexachloride in original sample.

## 6.197

**Melting Point Determination of the Gamma Fraction**

Dissolve residue in min. amt acetone and transfer quant. to 10 mL beaker. Evap. acetone at  $40^\circ$ , using filtered air stream. Scrape residue from beaker for mp detn. (Beaker may be set on piece of solid  $\text{CO}_2$  to ensure prepn of finely powd product.) Place material in agate mortar and mix thoroly with pestle.

Select 2 clean, dry capillary tubes and fill with sample. Be sure material is well packed into bottom of tube to ensure max. contact between sample and wall of tube. Insert tubes and

thermometer bulb in Thiele tube so that samples and thermometer bulb touch. Start stirrer and heater, and adjust heating rate to 1°/min at 90°. Continue heating until sample melts or reaches 106°. Reduce heating rate to 0.5°/min and continue heating until sample melts.

Sample mp is corrected temp. of bath when last solid disappears into the clear melt. If mp is <108°, check result by IR method, 6.198–6.201.

**Infrared Spectrophotometric Method (57)**  
**Official Final Action**

(Applicable to tech. BHC. *Caution:* See 51.018, 51.041, and 51.048.)

## 6.198

**Apparatus**

*Infrared spectrometer.*—With matched pair of liq. absorption cells, 0.5–1.1 mm thick.

## 6.199

**Calibration of Cells**

Det., in spectrometer, difference between deflections of the 2 cells filled with CS<sub>2</sub>. Plainly mark one cell to be used as sample cell for reading *I*. Correct values of *I*<sub>0</sub> obtained with other cell by adding or subtracting difference between cells and refer to this as cell factor *F*. Check factor every 10–14 days.

## 6.200

**Preparation of Standards and Working Curves**

Obtain α, β, γ, and δ isomers of BHC, either by fractional crystn from tech. material or as sepd materials, and recrystallize several times from solvs that have been redistd from all-glass app. Recrystallize from following solvs until mps by capillary tube method become const: α isomer from benzene followed by MeOH (mp ca 158°); β isomer from toluene (mp ca 210.5°, sealed capillary); γ isomer from MeOH (mp ca 113°); and δ isomer from CCl<sub>4</sub> followed by CHCl<sub>3</sub> (mp ca 138.5°).

Confirm purity of each isomer as follows: Evap. to dryness enough mother liquor from last crystn to yield ≥1 g dissolved solids, grind residue, and dry overnight in evacuated desiccator. Weigh and dissolve in enough CS<sub>2</sub> to make 4 g/100 mL soln. Prep. corresponding soln of recrystd isomer as std. Compare solns of residue and std in spectrometer at wavelength points used for analysis of other isomers. Consider purity of isomer satisfactory if *A* of residue soln is not significantly greater than that of std at these points.

Prep. working curves of the isomers by detg *T* of their solns in CS<sub>2</sub> at various concns as in 6.201. Calc. *A* and plot against concn in g/L.

## 6.201

**Determination**

Reduce sample of tech. BHC to ca 2 g by grinding and quartering, and dry 24 hr *in vacuo* at room temp. Weigh 1.5000 g dried material into 50 mL vol. flask and dil. to vol. with CS<sub>2</sub> (equiv. to 30 g/L). Shake vigorously to dissolve (β isomer is not completely sol. and will settle out). Pipet 25 mL of this sample soln into another 50 mL vol. flask and again dil. to vol. with CS<sub>2</sub> (equiv. to 15 g/L). Fill sample cell with the concd soln for reading *I*, and fill blank cell with CS<sub>2</sub>, place in spectrometer, and read *T* in duplicate at following wavelengths:

*Wavelength, μm*

Alpha	12.58
Beta	13.46
Gamma	14.53
Delta	13.22
Epsilon	13.96

Average duplicates for calcns. Repeat readings with dil. soln (15 g/L) at α and γ wavelengths. Calc. *A* of each of isomers at the various wavelengths from *T* measurements by equation:

$$\text{Log} \frac{(F \times I_b) - (F \times I_b \times \% \text{Sct})}{I_s - (F \times I_b \times \% \text{Sct})} = A,$$

where *F* = cell factor, *I*<sub>b</sub> = reading of blank cell, % Sct = % scatter, *I*<sub>s</sub> = reading of sample cell, and *A* = absorbance.

Obtain approx. concns from working curves, 6.200. Correct *A* at each wavelength for absorption of interfering components. (Altho β isomer has low solubility in CS<sub>2</sub>, this isomer interferes with δ analytical point; therefore det. *A* of β isomer in CS<sub>2</sub> at this point and apply as correction.) Since these new values are overcorrected, make repeated evaluations until successive values are const, within desired precision.

**6.202 ★ Radioactive Tracer Method (58) ★**  
**Official First Action**

See 6.257–6.260, 11th ed.

***N*-Butyl-*N*-ethyl-α,α,α-trifluoro-2,6-dinitro-*p*-toluidine**  
**(Balan®) or Trifluralin (α,α,α-Trifluoro-2,6-dinitro-*N,N*-**  
**dipropyl-*p*-toluidine (59)—Official Final Action**

**Ultraviolet Method**

## 6.203

**Principle**

Trifluralin or Balan is extd from solid carrier or dissolved in *n*-hexane if liq., purified by chromatgy on Florisil, and detd by UV spectrometry at 376 nm.

## 6.204

**Reagents**

(a) *Florisil.*—100–200 mesh. Test elution characteristics of Florisil by adding 5 mL std soln to prepd column. Proceed as in 6.207. Elution vol. should be ≥80 mL but <100 mL. If elution vol. does not fall within this range, adjust H<sub>2</sub>O content of Florisil by trial and error to obtain proper elution (add H<sub>2</sub>O to decrease elution time; dry at 130° to increase it).

(b) *Std soln.*—1.25 mg/mL. Weigh 0.125 g trifluralin or Balan Ref. Std (Elanco Products Co.), into 100 mL vol. flask, dil. to vol. with *n*-hexane, and mix.

## 6.205

**Preparation of Column**

Insert glass wool plug in bottom of 25 × 400 mm glass tube with Teflon stopcock. Add, with const tapping of column, 5 g anhyd. Na<sub>2</sub>SO<sub>4</sub>, stdzd Florisil, (a), to ht of 50 mm, and 5 g anhyd. Na<sub>2</sub>SO<sub>4</sub>. With stopcock open, add 50 mL *n*-hexane and let drain to top of column. Close stopcock.

## 6.206

**Preparation of Sample**

(a) *Dry formulations (containing more than 1% trifluralin or Balan).*—Weigh sample contg 0.25 g trifluralin or Balan into Soxhlet extn thimble (33 × 80 mm), cover with glass wool, and ext with CHCl<sub>3</sub> 1 hr beyond time when no further color is extd. Quant. transfer ext to 200 mL vol. flask with CHCl<sub>3</sub>, dil. to vol. with CHCl<sub>3</sub>, and mix. Transfer 5 mL to r-b flask and evap. *just* to dryness on rotary evaporator.

(b) *Dry formulations (containing 1% or less trifluralin or Balan).*—Weigh sample contg 0.05 g trifluralin or Balan, ext, transfer to 200 mL vol. flask, and dil. as in (a). Transfer 25 mL to r-b flask and evap. *just* to dryness on rotary evaporator.

(c) *Liquid formulations.*—Weigh sample contg 0.12 g trifluralin or Balan into 100 mL vol. flask. Dil. to vol. with *n*-hexane and mix vigorously. Proceed as in 6.207.

★ Surplus method—see inside front cover.

**6.207****Determination**

Transfer 5 mL soln from (c) or residue from (a) or (b), with aid of *n*-hexane, to Florisil column. Transfer 5 mL std soln to second Florisil column. Wash sample into column with small portions *n*-hexane. Let each portion drain to top of column before adding next. Fill column with *n*-hexane, discarding eluate until band has moved ca ¼ length of column. Collect eluate contg trifluralin or Balan band (first yellow-orange band to elute) in 100 mL vol. flask. (If band requires >100 mL vol. to elute, replace vol. flask with r-b flask, evap., and transfer quant. to 100 mL vol. flask.) (Caution: See 51.011(a) and 51.061.) Dil. to vol. with *n*-hexane and mix. Det. *A* of sample and std solns in 1 cm cells at 376 nm against *n*-hexane as ref.

**6.208****Calculations**

% Trifluralin or Balan =  $(A \times g \text{ std} \times F \times P) / (A' \times g \text{ sample})$ , where *A* and *A'* refer to sample and std solns, resp.; *P* = % purity of std; and *F* = 2, 0.4, or 1 for sample preps (a), (b), or (c), resp.

**Gas-Liquid Chromatographic Method****6.209****Principle**

Trifluralin or Balan is extd from solid carrier, or dissolved in acetone if liq., and detd by GLC.

**6.210****Reagents**

(a) *Diisobutyl phthalate internal std soln.*—Weigh 0.625 g diisobutyl phthalate (ICN-K&K Laboratories, Inc.) into 250 mL vol. flask, dil. to vol. with acetone, and mix.

(b) *Std soln.*—1.6 mg/mL. Weigh 0.16 g trifluralin or Balan. Ref. Std into 100 mL vol. flask, dil. to vol. with acetone, and mix.

**6.211****Apparatus**

(a) *Gas chromatograph.*—Equipped with flame ionization detector; capable of programmed column temp. from 135 to 190° at 8°/min. Approx. instrumental conditions: inlet 205°, detector 275°, N carrier gas 60 mL/min.

(b) *Column.*—1.5 m (5') × ⅛ or ¼" od, stainless steel or Pyrex glass tube packed with 5% DC 200, 12,500 cstokes (Analabs, Inc.) on 80–100 mesh Chromosorb W (HP). Condition newly prepd column at 230° overnight with N carrier gas.

**6.212****Preparation of Sample**

(a) *Dry formulations (containing more than 1% trifluralin or Balan).*—Weigh sample contg 0.16 g trifluralin or Balan into Soxhlet extn thimble (33 × 80 mm), cover with glass wool, and ext with acetone 1 hr beyond time when no further color is extd. (Caution: See 51.011(a) and 51.046.) Evap. to ca 60 mL on steam bath with stream of air directed into flask. Transfer quant. to 100 mL vol. flask with acetone. Dil. to vol. with acetone and mix.

(b) *Dry formulations (containing 1% or less trifluralin or Balan).*—Weigh sample contg 0.04 g trifluralin or Balan, ext, and evap. as in (a). Transfer quant. to 100 mL vol. flask with acetone and proceed as in 6.213 without dilg, beginning, "... add 10 mL internal std soln, ..."

(c) *Liquid formulations.*—Weigh sample contg 0.16 g trifluralin or Balan into 100 mL vol. flask, dil. to vol. with acetone, and mix.

**6.213****Determination**

Pipet 25 mL acetone soln, 6.212(a) or (c), and 25 mL std soln, (b), into sep. 100 mL vol. flasks, add 10 mL internal std soln, dil. to vol. with acetone, and mix.

Inject 2.5 µL trifluralin or Balan std soln and start temp. program to give symmetrical peak ca 70% scale deflection and retention time 5.5 min. Diisobutyl phthalate internal std peak appears ca 2 min after std peak. Repeat injection of std soln until ratio of trifluralin or Balan peak area to internal std peak area is reproducible.

Without changing conditions inject 2.5 µL sample soln.

**6.214****Calculations**

Calc. areas of trifluralin or Balan and diisobutyl phthalate peaks. Divide area of trifluralin or Balan peak by area of diisobutyl phthalate internal std peak to det. ratio, *R*.

$$\% \text{ Trifluralin or Balan} = (R \times W' \times P) / (R' \times W \times F),$$

where *R* and *R'* = ratio for sample and std solns, resp.; *W* and *W'* = g sample and std, resp.; *P* = % purity of std; and *F* = 1, 1, or 4 for sample preps (a), (c), or (b), resp.

**Captan (N-(Trichloromethylthio)-4-cyclohexene-1,2-dicarboximide) (60)—Official First Action**

**AOAC-CIPAC Method**

(Caution: See 51.039 and 51.041.)

**6.215****Principle**

Captan is extd from inerts with soln contg dieldrin in dioxane. Ratio of captan peak ht to dieldrin peak ht in gas chromatgy is measured and compared to ratio from std captan prep similarly. Method applies to tech. and dry formulated products contg captan as only active ingredient.

**6.216****Reagents**

(a) *Extracting soln.*—Weigh ca 5.0 g dieldrin (ca 85% HEOD) into 500 mL vol. flask, add ca 300 mL 1,4-dioxane, shake to dissolve dieldrin, and dil. to vol. with dioxane.

(b) *Captan std soln.*—Accurately weigh, by difference, 0.25 g captan ref. std into glass vial. Pipet 25 mL extg soln into vial, stopper, and shake until dissolved. Prep. fresh after 24 hr.

**6.217****Gas Chromatography**

Use any app. that will completely sep. captan from HEOD and with following conditions: Sample inlet port 10–30° higher than column; thermal conductivity or H flame detector maintained ≥20° higher than column (typical column temp. 220°); 1.5 m (5') × ¼" od glass column packed with 3% XE-60 silicone nitrile gum rubber on Chromosorb G, acid-washed and dimethyl dichlorosilane-treated (allowable variations are 0.6–1.8 m (2–6'), ⅛–¼" od, 2–10% liq. loading, Chromosorb W). Condition newly prepd column at 230° overnight while purging with carrier gas (He for thermal conductivity or N for H flame detectors).

**6.218****Preparation of Sample**

Accurately weigh, by difference, well mixed portion of sample contg ca 0.25 g captan into 30 mL glass vial with plastic-lined screw cap. Into vial pipet 25 mL same extg soln used for prep of std soln. Stopper and shake mech. 15 min. Centrf. if necessary to ppt inerts. Sample supernate with syringe for captan detn. Prep. fresh after 24 hr.

**6.219****Determination**

Adjust column temp., carrier gas flow, injection size, and recorder attenuation so that captan and HEOD peaks are completely sep'd in <10 min and so that ht of HEOD peak, which elutes first, is ca ¾ full scale. Repeat injections of std soln until peak ht ratio captan:HEOD of 2 consecutive injections varies

<2%. Without changing conditions, inject supernate from sample. If sample ratio differs by  $\geq 10\%$  from std ratio, reweigh sample. For detn, inject std, sample in duplicate, and std.

Measure HEOD and captan peak hts. When solv. peak tailing extends into region of HEOD and captan peaks, draw curved extension as baseline. Det. peak ht ratio captan:HEOD and average the 2 values ( $R_s$ ) for std injections just before and after sample injections. Calc. and average peak ht ratio of the 2 samples ( $R_x$ ).

$$\% \text{ Captan} = (R_x/W_x) \times (W_s \times P/R_s),$$

where  $W_s$  = g std,  $W_x$  = g sample, and  $P$  = % purity of captan std.

#### Technical Chlordane

##### Total Chlorine Method (61)—Official Final Action

(Caution: See 51.011, 51.018, 51.038, 51.039, 51.040, 51.041, and 51.045.)

#### 6.220 Standardization of Standard Solutions

(a) *Sodium chloride std soln.*—0.1*N*. Dissolve 5.845 g NaCl, previously dried 2 hr at 105°, in H<sub>2</sub>O, and dil. to 1 L in vol. flask.

(b) *Silver nitrate std soln.*—0.1*N*. Prep. as in 50.027. To 250 mL g-s erlenmeyer add 15.00 mL 0.1*N* NaCl, (a), 50 mL H<sub>2</sub>O, 10 mL HNO<sub>3</sub> (1+1), boiled to expel oxides of N, and 25.00 mL of the AgNO<sub>3</sub> soln. Add 3 mL nitrobenzene, stopper, and shake vigorously 15 sec. Add 5 mL ferric indicator, 6.019(e), and back-titr. with 0.1*N* KSCN, (c), to reddish-brown end point. (Potentiometric titrn using Ag indicator electrode and Ag-AgCl or glass ref. electrode may be substituted for indicator method, but must be used in both stdzn and detn.)

(c) *Potassium thiocyanate std soln.*—0.1*N*. Prep. and titr. against AgNO<sub>3</sub> soln, (b), as in 50.030(b). Calc.  $F = \text{mL AgNO}_3 \text{ soln} / \text{mL KSCN soln}$ .

$$\text{Normality AgNO}_3 \text{ soln} = \text{mL NaCl soln} \times 0.1000 / (\text{mL AgNO}_3 \text{ soln} \div \text{mL KSCN soln} \times F).$$

#### 6.221 Preparation of Sample

(a) *Emulsifiable concentrate formulations.*—Accurately weigh sample contg 0.5±0.05 g tech. chlordane into 50 mL vol. flask, dissolve, and dil. to vol. with toluene. Transfer 5 mL aliquot to 125 mL separator, add 15 mL or g Na biphenyl reagent, 6.178(b), and swirl. If soln is not dark green, add more reagent. Let stand 3 min and add 3–5 mL H<sub>2</sub>O dropwise. With stopper removed, swirl soln gently to decompose excess reagent. Add 25 mL H<sub>2</sub>O, stopper, and mix with gentle rocking motion. (Do not shake vigorously.) Let layers sep. and drain lower aq. layer into 250 mL erlenmeyer. Re-ext solv. layer with two 25 mL portions 3*N* HNO<sub>3</sub> and combine aq. solns in erlenmeyer.

(b) *Dusts, granular impregnates, and wettable powders.*—Accurately weigh sample contg 0.5±0.05 g tech. chlordane into Soxhlet extn thimble. Ext with 80 mL benzene in Soxhlet app. 1 hr. Transfer to 100 mL vol. flask, washing with several 3 mL portions benzene. Dil. to vol. with benzene and transfer 10 mL aliquot to 125 mL separator. Proceed as in (a).

#### 6.222 Determination

Add 15.00 mL 0.1*N* AgNO<sub>3</sub> and 3 mL nitrobenzene to erlenmeyer, stopper, and shake vigorously 15 sec. Rinse stopper, add 5 mL ferric indicator, 6.019(e), and back-titr. with 0.1*N* KSCN to reddish-brown end point. (Designate mL KSCN as  $D$ .)

Det. blank on reagents by pipetting 5 mL toluene into 125 mL separator, add 15 mL or g Na biphenyl reagent, and proceed as in 6.221(a), thru combining aq. solns in erlenmeyer. Add 15.00

mL 0.1*N* NaCl, 25.00 mL 0.1*N* AgNO<sub>3</sub>, and 3 mL nitrobenzene, and proceed as above. Calc. blank correction factor,  $C = \text{mL KSCN used in stdzn of AgNO}_3 - \text{mL KSCN used in blank detn}$ .

$$\% \text{ Chlorine} = [15 - (C + D) \times F] \times \text{normality AgNO}_3 \times 3.545 / \text{g sample}.$$

$$\% \text{ Tech. chlordane} = \% \text{ Cl} \times 1.56.$$

#### Colorimetric Method (62)—Official Final Action

(Method is empirical; all conditions must be reproduced exactly to attain good precision. Temp., reaction time, and vol. of reagents affect color intensity.)

#### 6.223

##### Apparatus

(a) *Constant temperature bath.*—Capable of maintaining 100±1° and holding twelve 20 × 150 mm test tubes.

(b) *Cuvets.*—10 or 2 mm light path (available from Pyrocell Mfg. Co., 91 Carver Ave, PO Box 176, Westwood, NJ 07675).

(c) *Spectrophotometer.*—Capable of accepting cuvetts, (b).

#### 6.224

##### Reagents

(a) *Methanol.*—90% (by vol.).

(b) *Methanol-benzene.*—Mix 7 vols MeOH with 3 vols benzene.

(c) *Diethanolamine.*—Purify by vac. distn at ca 20 mm Hg and take middle fraction. (Caution: See 51.011 and 51.015.)

(d) *Diethanolamine-KOH soln (Davidow reagent).*—Mix 1 vol. reagent (c) with 2 vols 1.0*N* KOH in MeOH.

(e) *Chlordane std solns.*—1.5, 2.5, and 3.5 mg/mL. Ref. grade (available from Velsicol Chemical Corp.). Dissolve tech. chlordane in reagent (b). Discard stds after 2 weeks.

#### 6.225

##### Preparation of Sample

(a) *Liquid formulations.*—Transfer weighed sample contg 200–300 mg tech. chlordane to 100 mL graduate and dil. to 100 mL with MeOH-benzene.

(b) *High concentration solid formulations (10% chlordane or more).*—Treat as in (a) and shake vigorously several min. Let settle 1 hr.

(c) *Low concentration solid formulations (less than 10% chlordane).*—Transfer weighed sample contg 200–300 mg tech. chlordane to Soxhlet and ext 1 hr with pentane. (Caution: See 51.039 and 51.074.) Evap. pentane on steam bath and transfer ext to 100 mL g-s graduate. Dil. to 100 mL with MeOH-benzene.

#### 6.226

##### Determination

Pipet 2 mL aliquot prepd sample to 20 × 150 mm test tube. Add No. 8 grit SiC boiling chip and 2 mL Davidow reagent, and place in 100° const temp. bath. Remove after exactly 45 min and cool immediately in beaker of cold H<sub>2</sub>O. Transfer to 10 mL vol. flask and dil. to vol. with 90% MeOH. Transfer aliquot of soln to 2 mm cell and read  $A$  at 550 nm within 15 min with 90% MeOH as ref. (Comparable results are obtained by dilg soln to 50 mL and using 1 cm cell.)

Treat 2 mL each std soln with each set of samples. (Read 1 std soln before samples, 1 after half the samples are read, and 1 after last sample is read.)

#### 6.227

##### Calculations

Calc. absorptivity ( $a$ ) for each of 3 stds, and use av. in subsequent calcs (expected  $a$  is ca 0.25):  $a = A'/W$ , where  $A' = A$  std soln and  $W$  = mg tech. chlordane (2 × concn std soln in mg/mL).

$$\% \text{ Tech. chlordane in sample} = A \times 5000 / (a \times \text{mg sample}).$$

### Hexachlorocyclopentadiene (HEX) (63)—Official Final Action

(Applicable to tech. chlordane, but not to formulations)

#### 6.228

#### Reagent

*Hexachlorocyclopentadiene (HEX) std solns.*—Stock soln.—0.1 g/100 mL. Weigh 0.1000 g hexachlorocyclopentadiene Ref. Std (available from Velsicol Chemical Corp.) in 100 mL vol. flask, dil. to vol. with MeOH, and shake to dissolve. *Std soln 1.*—0.005 g/100 mL. Dil. 5 mL stock soln to 100 mL with MeOH. *Std soln 2.*—0.002 g/100 mL. Dil. 2 mL stock soln to 100 mL with MeOH.

#### Method I

#### 6.229

#### Calibration

With MeOH in both ref. and sample cells (matched 1 cm silica), adjust 0 and 100% settings on UV spectrophtr at 324 nm. Empty sample cell, rinse several times with, and then fill with, *std soln 1*, and read *A*. Empty sample cell, rinse with MeOH, then rinse and fill with *std soln 2*, and read *A*. Calc. *A* factor, *K*, for each std soln = (g std HEX/100 mL)/*A*. Average the two *K* values.

#### 6.230

#### Determination

Weigh 0.5 g sample in 100 mL vol. flask, dil. to vol. with MeOH, and shake to dissolve. Proceed as in 6.229, treating sample soln in same manner as stds.

$$\% \text{ HEX in sample} = (A \text{ of sample soln} \times 100 \times K) / (\text{g sample} / 100 \text{ mL}).$$

#### 6.231

#### Method II

(Includes corrections for other components of chlordane which absorb at 324 nm)

Proceed as in 6.229–6.230, except det. *A* of all solns at 300, 324, and 350 nm. Settings of 0 and 100% must be repeated at 300, 324, and 350 nm for *A* readings at those points. Calc. *K* = (g std HEX/100 mL) / [*A*<sub>324</sub> – 0.5(*A*<sub>300</sub> + *A*<sub>350</sub>)].

$$\% \text{ HEX in sample} = [A_{324} - 0.5(A_{300} + A_{350})] \times 100 \times K / (\text{g sample} / 100 \text{ mL}).$$

### AG Chlordane (Octachloro-4,7-methanotetrahydroindane) (64)—Official Final Action

#### $\alpha$ - and $\gamma$ -Isomers in Technical Products—Infrared Method

(Not applicable to tech. chlordane or its formulations)

#### 6.232

#### Apparatus and Reagent

(a) *Infrared spectrophotometer.*—Double beam, with matched NaCl cells, 0.1 and 0.2 mm.

(b) *Std soln.*—Into tared 10 mL vol. flask, weigh 1.00±0.05 g ref. std  $\alpha$ -chlordane and 0.38±0.02 g ref. std  $\gamma$ -chlordane (Velsicol Chemical Corp.), dissolve in CS<sub>2</sub>, and dil. to vol. with CS<sub>2</sub>.

#### 6.233

#### Preparation of Sample

Melt entire sample in 100° oven and mix. Weigh 1.5±0.02 g into tared 10 mL vol. flask, dissolve in CS<sub>2</sub>, and dil. to vol. with CS<sub>2</sub>.

#### 6.234

#### Determination

(a)  $\alpha$ -Chlordane.—Fill ref. cell with CS<sub>2</sub>. Scan std and sample solns from 750 to 710 cm<sup>-1</sup> (13.3 to 14.1  $\mu$ m), using 0.1 mm NaCl cells. Construct baseline from 738 to 715 cm<sup>-1</sup> (13.6 to 14.0  $\mu$ m) and draw line from point of max. *A*, ca 725 cm<sup>-1</sup> (13.8  $\mu$ m), to intersect baseline.

(b)  $\gamma$ -Chlordane.—Fill ref. cell with CS<sub>2</sub>. Scan std and sample solns from 1390 to 1290 cm<sup>-1</sup> (7.19 to 7.75  $\mu$ m), using 0.2 mm NaCl cells. Proceed as in (a), using min. at 1370 and 1310 cm<sup>-1</sup> (7.30 and 7.63  $\mu$ m), and det. *A* at max. 1320 cm<sup>-1</sup> (7.58  $\mu$ m).

#### 6.235

#### Calculations

$$\text{Wt } \% \alpha(\text{-chlordane}) \text{ or } \gamma(\text{-chlordane}) = (A \times F \times 100) / W_s$$

$$F = [W(\alpha \text{ or } \gamma \text{ in std}) \times \% \text{ purity in std}] / A'(\alpha \text{ or } \gamma \text{ of std}),$$

where *W* = wt (g), and *A* and *A'* refer to sample and std, resp.

(Wts given are for cell thicknesses specified. For other cells, adjust wts to yield peak *A* between 0.2 and 0.5 (30–65% *T*).)

### AG Chlordane in Granular Formulations—Infrared Method

(Not applicable to tech. chlordane or its formulations. *Caution:* See 51.011, 51.041, 51.046, and 51.048.)

#### 6.236

#### Apparatus

(a) *Infrared spectrophotometer.*—See 6.232.

(b) *Soxhlet extraction apparatus.*—With 25 × 80 mm Whatman cellulose thimble.

(c) *Vigreux distilling tube.*—15 mm long.

(d) *Vials.*—5 dram, with plastic-lined screw caps.

#### 6.237

#### Reagents

(a) *Acetone.*—Spectral grade.

(b) *Std soln.*—Into tared 5 dram vial, weigh 1.00±0.05 g Ref. Std  $\alpha$ -Chlordane and 0.38±0.02 g Ref. Std  $\gamma$ -Chlordane (Velsicol Chemical Corp.) and pipet in 10 mL CS<sub>2</sub>.

#### 6.238

#### Preparation of Sample

Into tared thimble, weigh sample equiv. to wt of std and cover with glass wool. Insert into extn app. and attach to 250 mL flat-bottom  $\frac{3}{8}$  flask contg boiling chips. Add 125 mL acetone, attach extractor to condenser, and ext 1 hr.

Rinse extn app. with acetone. Sep. flask from extractor and condenser, attach distg tube to flask, and evap. acetone on steam bath. Remove tube, add 5 mL CS<sub>2</sub>, and evap. carefully. Repeat addn and evapn of CS<sub>2</sub> 4 more times. (All residual acetone must be removed because acetone interferes with IR measurement.) Dry residue further, using forced air, until cryst. solid appears. Pipet 10 mL CS<sub>2</sub> into flask, and swirl carefully to dissolve solid. Release stopper pressure.

#### 6.239

#### Determination

Proceed as in 6.234.

#### 6.240

#### Calculation

Proceed as in 6.235 for calcn of wt %.

$$\% \text{ Total AG chlordane} = \% \alpha\text{-chlordane} + \% \gamma\text{-chlordane}.$$

Generally, factor representing specification grade of 95% AG chlordane may be used. Then,

$$\% \text{ AG chlordane} = \% \text{ total } (\alpha + \gamma) \times 1.053.$$

### Heptachlor in AG Chlordane—Gas Chromatographic Method

(Not applicable to tech. chlordane or its formulations)

#### 6.241

#### Apparatus and Reagents

(a) *Gas chromatograph.*—Equipped with flame ionization detector and 1.5 m (5') ×  $\frac{1}{8}$ " id glass column packed with 5% silicone DC 200 (Viscosity 12500, Analabs, Inc.) on 130–140 mesh

Anakrom ABS. Operating conditions: temps (°)—column 165, injector 215, detector 220; N carrier gas 30 mL/min (ca 80 psig at inlet); and chart speed 0.5"/min.

(b) *Stds.*—Ref. Std  $\alpha$ -Chlordane,  $\gamma$ -Chlordane, and Heptachlor (Velsicol Chemical Corp.) and hexachlorobenzene ( $C_6Cl_6$ ) internal std (Eastman Kodak Co.), recrystd from benzene.

(c) *Std soln.*—Accurately weigh following components into 10 mL vol. flask, dissolve in  $CS_2$ , and dil. to vol.: 0.48 g  $\alpha$ -chlordane, 0.18 g  $\gamma$ -chlordane, 0.010 g  $C_6Cl_6$ , and 0.010 g heptachlor.

## 6.242

**Preparation of Sample**

Melt entire sample in 100° oven and mix. Accurately weigh 0.73 g sample and 0.010 g  $C_6Cl_6$  into 10 mL vol. flask, and dil. to vol. with  $CS_2$ .

## 6.243

**Determination**

Inject 1.5  $\mu$ L sample soln into gas chromatograph; retention times for  $C_6Cl_6$  and heptachlor are ca 2 and 4 min, resp. Also inject 1.5  $\mu$ L std soln to det. response factor (RF).

Use attenuation (ca 2 $\times$ ) to keep internal std peak on scale and include in calcs.

## 6.244

**Calculations**

Calc. each peak area by any convenient means. Built-in integrators or planimeters provide most accurate method of detg areas where peaks are not perfectly symmetrical.

$$\% \text{ Heptachlor} = (PH \times RF \times WI \times 100) / (PI \times W)$$

$$RF = (PI \times W') / (PH' \times WI),$$

where PH, PH', and PI = peak areas of sample, std heptachlor, and internal std, resp.; W, W', and WI = g sample, std heptachlor, and internal std, resp.

**Chlorotoluron [3-(3-Chloro-4-methylphenyl)-1,1-dimethylurea], Chloroxuron [3-[4-(4-chlorophenoxy)phenyl]-1,1-dimethylurea], or Metoxuron (Dosanex®)[3-(3-Chloro-4-methoxyphenyl)-1,1-dimethylurea] (65)—Official Final Action**

**CIPAC-AOAC Method**

## 6.245

**Principle**

Pesticide is extd from formulations with  $CH_2Cl_2$ , free amines are removed with acid, and ext is hydrolyzed by alkali to  $Me_2NH$  which is distd and titrd. Related byproducts, 3-(3-chloro-4-methylphenyl)-1-methylurea (I), 3-(4-methylphenyl)-1,1-dimethylurea (II) (from chlorotoluron), 3-[4-(4-chlorophenoxy)phenyl]-1-methylurea (III) and 3-(4-chlorophenyl)-1,1-dimethylurea (IV) (from chloroxuron), and 3-(3,4-dichlorophenyl)-1,1-dimethylurea (V), 3-(3-chloro-4-hydroxyphenyl)-1,1-dimethylurea (VI), and 3-(4-methoxyphenyl)-1,1-dimethylurea (VII) (from metoxuron), which may interfere, are detd by semiquant. TLC. Limit of detection for TLC is 0.1% for each byproduct. On same TLC plate for chloroxuron, free amine 4-(4-chlorophenoxy)aniline (VIII) is detd by sep. detection technic. Other byproducts, 1,3-bis(3-chloro-4-methylphenyl) urea (IX), 1,3-bis[4-(chlorophenoxy)phenyl] urea (X), and 1,3-bis(3-chloro-4-methoxyphenyl) urea (XI), do not interfere with chlorotoluron, chloroxuron, and metoxuron detns, resp.

## 6.246

**Preparation of Sample**

(a) *Technical formulation.*—Accurately weigh ca 3 g sample (4 g for chloroxuron) and transfer, using 100 mL  $CH_2Cl_2$ , into 250 mL separator, dissolve, and add 50 mL 1N HCl.

(b) *Wettable powder.*—Accurately weigh ca 3.5–4.0 g sample

(for 80%) or 6.0–6.5 g (for 50%) into 200 mL beaker. Add 100 mL  $CH_2Cl_2$  and stir mag. 5 min. Filter thru fritted glass crucible contg paper and 0.5 g layer of Celite, and rinse beaker and crucible with portions of  $CH_2Cl_2$  to total vol. of ca 200 mL. Use only slight vac. to prevent crystn of pesticide on walls of crucible. Transfer quant. to 500 mL separator, and add 50 mL 1N HCl.

## 6.247

**Determination**

Vigorously shake mixt. 1 min and drain lower org. layer into second separator. Add 25 mL (50 mL for chloroxuron) 1N HCl, shake 30 sec, and drain lower layer into 500 mL r-b flask. Wash the 2 acid layers successively with same 100 mL portion  $CH_2Cl_2$  (with two 50 mL portions for chloroxuron) and drain lower layer into the 500 r-b flask. Discard acid.

Vac.-evap.  $CH_2Cl_2$  in rotary evaporator to dryness at max. of 40°. Remove all solv. to prevent interference in subsequent titrn. Add 100 mL propylene glycol, 40 g KOH, and some boiling stones to residue. Immediately connect flask securely to distn app. (Fig. 6:06) whose joints are lubricated with thin film of silicone grease. Place end of condenser delivery tube ( $\geq 10$  mm id) in 400 mL beaker below level of absorbing soln of 0.2 g  $H_3BO_3$  and 1 mL mixed indicator soln (40 mg methylene blue and 60 mg Me red dissolved in 100 mL alcohol) in 150 mL  $H_2O$ . (To enhance end point, use 150 mL MeOH (2+1).)

Gently warm flask until all particles dissolve; then boil 10 min or until propylene glycol distils into condenser. Titrd.  $Me_2NH$  continuously with stdzd 1N HCl, 50.011–50.017. Complete distn by carefully adding  $H_2O$  dropwise from dropping funnel at rate of 1 drop/sec. Continue titrn until end point persists 2 min (V mL). Perform blank detn (B mL) with each series.

$$\% \text{ Pesticide} = [(V - B) \times N \times F / \text{g sample}]$$

$$- \% \text{ byproducts (from 6.248),}$$

where F = 21.27 for chlorotoluron, 29.07 for chloroxuron, or 22.87 for metoxuron, and N = normality of stdzd HCl.

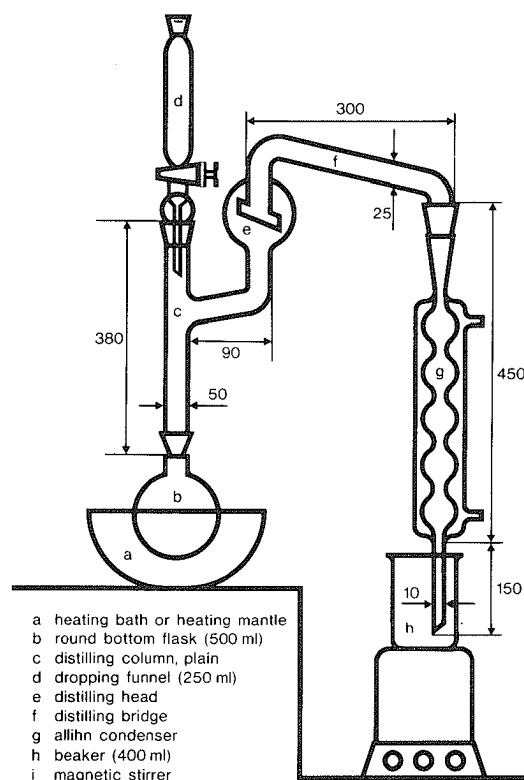

FIG. 6:06—Distillation apparatus (all dimensions in mm)

## 6.248

**Determination of Byproducts**

(a) *For chlorotoluron.*—Dissolve 100 mg each of byproducts I and II (6.245) (available from Ciba-Geigy Ltd, Analytical Department, CH-4002 Basel, Switzerland) together in tetrahydrofuran and dil. to 50 mL in vol. flask. Dil. aliquots of 1, 2, 3, 4, and 5 mL to 20 mL with tetrahydrofuran, equiv. to 0.2, 0.4, 0.6, 0.8, and 1.0%, resp., of each byproduct.

Dissolve 1.0 g sample in tetrahydrofuran, and dil. to 20 mL with same solv.

Spot 5  $\mu$ L each of sample and std solns on 20  $\times$  20 cm glass plates precoated with 0.25 mm layer of silica gel 60 F-254 (No. 5715, E. Merck, Darmstadt, Germany, or equiv.), and develop by ascending technic in tank, presatd 30 min with developing solv.  $\text{CHCl}_3$ -EtOAc (4+1), without filter paper linings, for ca 70 min (13 cm migration). Expose plate to 254 nm UV light and compare spots of samples with those of stds to est. concn of byproducts. Approx  $R_f$  values: chlorotoluron, 0.50; byproduct I, 0.25; byproduct II, 0.35; and byproduct VI (does not interfere), 0.82.

(b) *For chloroxuron.*—Dissolve 100 mg each of byproducts III, IV, and VIII (available from Ciba-Geigy Ltd) together in acetone and dil. to 100 mL in vol. flask. Dil. aliquots of 1, 3, 5, 8, and 10 mL to 50 mL with acetone, equiv. to 0.1, 0.3, 0.5, 0.8, and 1% resp., of each byproduct.

Dissolve 1.0 g sample in acetone, and dil. to 50 mL with same solv. Proceed as in (a), but use  $\text{CHCl}_3$ -dioxane (9+2) as developing solv. for ca 80 min (14 cm). Approx  $R_f$  values: chloroxuron 0.75; byproduct III, 0.40; byproduct IV, 0.65; and byproduct X (does not interfere), 0.90.

Det. byproduct VIII on same TLC plate. Place beaker contg ca 2 g  $\text{NaNO}_2$  in empty developing tank and pour ca 3 mL HCl over salt. After 2 min, insert plate into tank 3 min, remove, and dry 5 min at room temp. with hair dryer. Spray with 1% soln of *N*-(1-naphthyl)ethylenediamine.2HCl in 0.1*N* HCl and compare violet sample spots with those of stds ( $R_f$ , 0.85).

(c) *For metoxuron.*—Proceed as in (a), except use 100 mg each of byproducts V, VI, and VII (available from Sandoz Ltd, Agrochemical Division, Research, CH-4002 Basel, Switzerland). Approx  $R_f$  values: metoxuron, 0.25; byproduct III, 0.34; byproduct IV, 0.08; byproduct V, 0.13; and byproduct VII (does not interfere), 0.46.

## 6.249

**Identification**

(a) *Technical chloroxuron.*—Record IR spectrum of 1%  $\text{CH}_2\text{Cl}_2$  soln of sample and compare with spectrum of 1%  $\text{CH}_2\text{Cl}_2$  soln of authentic ref. std.

(b) *50% Wettable powder.*—Stir ca 2 g sample and 2 g silica gel (70–230 mesh) with 100 mL  $\text{CH}_2\text{Cl}_2$  5 min and percolate thru fluted filter. Record IR spectrum of filtrate in NaCl cell (0.5 mm path length) from 3000 to 650  $\text{cm}^{-1}$ , using blank solv. as ref. Identity is established if sample spectrum corresponds qual. to that of std.

**Dichlobenil (2,6-Dichlorobenzonitrile) (66)****CIPAC—AOAC Method**

## 6.250

**Reagents and Apparatus**

(a) *Dichlobenil.*— $\geq 99.5\%$  purity (Philips-Duphar B.V., Weesp, Netherlands), or equiv.

(b) *Methyl myristate.*—Fluka AG Cat. No. 70129,  $\geq 99.5\%$  purity (Fluka AG, Buchs, Switzerland), or equiv.

(c) *Mixed solvent soln.*—1,2-Dichloroethane-ether (1 + 1).

(d) *Internal std soln.*—Dissolve 0.80 g Me myristate, (b), in 100 mL mixed solv. soln, (c).

(e) *Calibration soln.*—Accurately weigh ca 0.10 g dichlobenil,

(a), into conical flask, pipet in 5 mL internal std soln, (d), and add 45 mL solv. soln, (c).

(f) *Gas chromatograph.*—With on-column injection, flame ionization detector, injection port heating, and, preferably, detector heating. Pyrex column 1.83 m  $\times$  3 mm id, packed with 10% Carbowax 20M on 100–120 mesh Chromosorb P, acid washed, dimethyldichlorosilane treated (available from Analabs, Cat. No. GCP-009D). Operating temps ( $^{\circ}$ ): oven 200, injection port 210, detector 210. Carrier gas (N) flow rate 25 mL/min. Approx. retention times 7 and 12 min for Me myristate and dichlobenil, resp.

## 6.251

**Preparation of Sample**

(a) *Technical dichlobenil.*—Accurately weigh ca 2.0 g dichlobenil into 100 mL vol. flask. Dissolve in mixed solv. soln, (c), and dil. to vol. Pipet 5 mL aliquot into 100 mL conical flask, add 5.00 mL internal std soln, (d), and dil. to 50 mL with mixed solv., (c).

(b) *Wettable powders.*—Accurately weigh sample contg ca 1.0 g dichlobenil into 100 mL vol. flask, add few mL mixed solv., (c), swirl, and dil. to vol. with mixed solv. Let settle, pipet 10 mL clear supernate into 100 mL conical flask, and continue as in (a).

(c) *Granules.*—Accurately weigh ca 6.0 g sample into 100 mL conical flask. Add 20 mL dichloroethane and stir 10 min on mag. stirrer. Filter with vac. thru glass filter paper (Whatman GF 82, or equiv.), supported on fritted glass filter. Wash granules 5 times with 5 mL dichloroethane, collect filtrate in 100 mL vol. flask, and dil. to vol. with ether. Pipet aliquot of this soln, contg ca 0.1 g dichlobenil (10 mL for 20% granules, 25 mL for 7% granules), into 100 mL conical flask, add 5.00 mL internal std soln, (d), and dil. to 50 mL with mixed solv., (c).

## 6.252

**Determination**

Inject 2  $\mu$ L portions of calibration soln, (e), until response factor varies  $<1\%$  for successive injections. Inject duplicate 2  $\mu$ L portions of sample soln, followed by 2  $\mu$ L portions of calibration soln, (e). Measure peak areas of dichlobenil and Me myristate, either by multiplying peak ht by retention time, or by digital integration. Use av. of duplicate values.

## 6.253

**Calculation**

$$p = (I_a \times r \times 20) / (I_i \times q),$$

where  $p$  = response factor,  $I_a$  and  $I_i$  = peak areas of internal std and dichlobenil, resp.,  $q$  = g internal std,  $r$  = g dichlobenil in calibration soln. (Response factor is ca 1.5.)

$$\% \text{ Dichlobenil} = (I_d \times q \times p \times F \times 100) / (I_m \times W \times 20),$$

where  $I_d$  and  $I_m$  = peak areas of dichlobenil and internal std, resp.,  $p$  = response factor,  $F$  = diln factor for sample (100/ $x$ ), where  $x$  = mL taken to obtain final soln), and  $W$  = g sample.

**Dichlorodiphenyltrichloroethane (1,1,1-Trichloro-2,2-bis(p-chlorophenyl) Ethane) (DDT)—Official Final Action****★ Total Benzene-Soluble Chlorine Method (67) ★**

(Applicable in absence of other org. Cl compds. Use  $\text{H}_2\text{O}_2$  and isoamyl alcohol-ether extn method on dispersible powders or sprays that contain surface active agents or other ingredients that react with  $\text{AgNO}_3$ . *Caution:* See 51.034, 51.039, 51.040, 51.041, and 51.045.)

## 6.254

**Reagents**

(a) *Benzene.*—Thiophene- and Cl-free.

(b) *Metallic sodium.*—Ribbons or small pieces.

★ Surplus method—see inside front cover.

(c) *Decolorizing carbon*.—Test for presence of Cl by heating with  $\text{HNO}_3$  (1+4), filtering, and adding  $\text{AgNO}_3$  soln to filtrate. If Cl is present, wash with the  $\text{HNO}_3$  until washings are Cl-free.

Note: Det. blank on all reagents, limiting 0.1N  $\text{AgNO}_3$  to 5 mL.

## 6.255

### Preparation of Solution

(a) *Technical grade DDT*.—Weigh sample contg ca 1 g DDT and transfer to 250 mL vol. flask. Dissolve sample in 10 mL benzene; then dil. to vol. with 99% *isopropanol*. Transfer 25 mL aliquot to 250–500 mL  $\text{Erlenmeyer}$ . (Direct weighing of sample may be substituted, provided it does not introduce error >0.1%.)

Add 2.5 g Na and shake to mix sample with *isopropanol*. Do not add Na thru top of condenser or get Na on ground glass joints. Connect flask to reflux condenser and boil gently  $\geq 30$  min, shaking occasionally. Eliminate excess Na by cautiously adding 10 mL 50% *isopropanol* thru condenser at rate of 1–2 drops/sec. Disconnect condenser, add 60 mL  $\text{H}_2\text{O}$ , boil soln ca 30 min to expel *isopropanol*, and proceed as in 6.256(a), (b), (c), or (d).

(b) *Dusting mixtures containing DDT in absence of organic matter*.—Weigh sample contg ca 0.75 g DDT, transfer to 100–200 mL vol. flask, and add exactly 100 mL benzene. Shake until DDT dissolves and soln is well mixed. Let settle and transfer 10 mL aliquot to 250–500 mL  $\text{Erlenmeyer}$ .

Evap. on steam bath to remove most of benzene. (Do not evap. to dryness, as DDT may decompose with loss of  $\text{HCl}$ .) Add 25 mL 99% *isopropanol* and proceed as in (a), second par.

If free S is present, proceed as in (f), beginning "Then add 5 mL 30%  $\text{H}_2\text{O}_2$ , ..."

(c) *Dusting mixtures in presence of organic matter (coloring matter, plant resins, etc.)*.—Weigh sample contg ca 0.75 g DDT, transfer to 100–200 mL vol. flask, and add 0.5–1.0 g decolorizing C and exactly 100 mL benzene. Shake until DDT dissolves and soln is well mixed. Filter into narrow-neck flask thru fast qual. paper without suction, keeping funnel covered with watch glass to avoid evapn loss. Transfer 10 mL aliquot to 250–500 mL  $\text{Erlenmeyer}$ . Proceed as in (b), second par. Before detg Cl remove org. matter as follows:

Cool, add 2–3 drops phthln, and neutze by adding  $\text{HNO}_3$  (1+1) dropwise; then 10 mL excess. Cool, if necessary, to room temp., transfer contents of flask and aq. washings to small separator, and shake with 15 mL *isoamyl alcohol-ether* (1+1). Drain aq. layer into second separator and ext again with 15 mL *isoamyl alcohol-ether* (1+1). Drain aq. layer into 250 mL beaker. Wash the 2 exts successively with two 10 mL portions  $\text{H}_2\text{O}$ . Combine aq. wash solns with aq. soln in beaker. Det. Cl by one of following methods:

(1) Proceed as in 6.256(a), beginning "Add slight excess 0.1N  $\text{AgNO}_3$ , ..."

(2) Proceed as in 6.256(b), beginning "Add 0.1N  $\text{AgNO}_3$ , ..."

(3) Proceed as in 6.256(c), beginning "Cool flask to room temp. ..."

(4) Add 2–3 drops phthln to sample, make alk. by adding 1N  $\text{NaOH}$ , and proceed as in 6.256(d), beginning "... transfer contents to Pt dish."

(d) *Mineral oil sprays in absence of organic matter (plant extractive material, organic thiocyanates)*.—Transfer weighed sample contg 0.065–0.075 g DDT to 250–500 mL  $\text{Erlenmeyer}$  flask. Add 25 mL 99% *isopropanol* and proceed as in (a), second par.

Note: If DDT content is <2%, use *isoamyl alcohol-ether* extn, (c), second par., to remove excess oil.

Proceed as in 6.256(a), (b), (c), or (d).

(e) *Mineral oil sprays in presence of organic matter (plant extractive material from pyrethrum or derris and/or cubé)*.—

Proceed as in (d), using *isoamyl alcohol-ether* extn, (c), to remove excess oil.

(f) *Mineral oil sprays in presence of organic thiocyanates with or without plant extractive material*.—Transfer sample contg 0.065–0.075 g DDT to 250–500 mL  $\text{Erlenmeyer}$ . Add 25 mL 99% *isopropanol* and proceed as in (a), second par., thru "... add 60 mL  $\text{H}_2\text{O}$ , ..." Then add 5 mL 30%  $\text{H}_2\text{O}_2$ , few drops at time, thru top of condenser, heat mixt. in flask to bp, and boil 15 min. Add addnl 5 mL  $\text{H}_2\text{O}_2$  and again boil 15 min. Add 15 mL more  $\text{H}_2\text{O}_2$ , disconnect reflux condenser, and boil 15–30 min to expel *isopropanol*. Proceed as in (c), second par.

(g) *Emulsions (solvent, emulsifier, and water)*.—Weigh well mixed sample contg ca 0.75 g DDT in weighing bottle. Wash into 100 mL vol. flask and dil. to vol. with *isopropanol*. Transfer 10 mL aliquot to 250–500 mL  $\text{Erlenmeyer}$ . Expel *isopropanol* and  $\text{H}_2\text{O}$  on steam bath in air current. If drops of  $\text{H}_2\text{O}$  still remain, add 10 mL *isopropanol* and repeat evapn. Add 25 mL 99% *isopropanol* and proceed as in (a), second par.

Note: If S is brought into the soln as by decomposition of emulsifier, proceed as in (f), beginning "Then add 5 mL 30%  $\text{H}_2\text{O}_2$ , ..."

## 6.256

### Determination

(a) Cool flask and transfer contents to 250 mL beaker. Add 2–3 drops phthln and neutze with  $\text{HNO}_3$  (1+1); then add 10 mL excess. Add slight excess 0.1N  $\text{AgNO}_3$ , 50.031, and coagulate pptd  $\text{AgCl}$  by digesting on steam bath 30 min, stirring frequently. Cool, filter thru fast qual. paper, and wash thoroly with  $\text{H}_2\text{O}$ . Add 5 mL satd ferric indicator, 6.019(e), and det. excess  $\text{AgNO}_3$  in filtrate by titrn with 0.1N  $\text{KSCN}$ , 50.030(b). Subtract amt  $\text{AgNO}_3$  found in filtrate from that originally added. Difference is that required to combine with Cl in the DDT. 1 mL 0.1N  $\text{AgNO}_3$  = 0.003545 g Cl.  $\text{Cl} \times 2 = \text{DDT}$ .

(b) Cool flask, add 2–3 drops phthln soln, and neutze with  $\text{HNO}_3$  (1+1); then add 10 mL excess. Add 0.1N  $\text{AgNO}_3$  from buret in excess of amt necessary to ppt all Cl; then add 5 mL *nitrobenzene* and 0.5 g  $\text{Fe}_2(\text{SO}_4)_3$  and swirl flask to coagulate ppt. Back-titr. excess  $\text{AgNO}_3$  with 0.1N  $\text{KSCN}$  to faint pink. Cross-titr. with both std solns, crossing end point in each direction to assure results. From vol.  $\text{AgNO}_3$ , calc. % DDT as in (a).

(c) Cool flask, add 2–3 drops phthln, neutze with  $\text{HNO}_3$  (1+1), and add 6 mL excess. Cool flask to room temp. and transfer contents to 400 mL beaker. (Vol. should be 200–250 mL.) Tit. Cl with 0.1N  $\text{AgNO}_3$  potentiometrically, using  $\text{Ag-AgCl}$  electrodes (Fisher Titrimeter, or equiv.). Calc. % DDT as in (a).

Note: When this method is used, decolorizing C step in 6.255(c), and *isoamyl alcohol-ether* extn in 6.255(c), (d), and (e), may be omitted.

(d) Cool flask and transfer contents to Pt dish. Evap. to dryness and ignite as thoroly as possible at  $\leq 525^\circ$ . Ext with hot  $\text{H}_2\text{O}$ , filter, and wash. Return residue to Pt dish and ignite to ash; dissolve in  $\text{HNO}_3$  (1+4), filter from any insol. residue, wash thoroly, and add this soln to aq. ext. Add 0.1N  $\text{AgNO}_3$ , avoiding more than slight excess. Heat to bp, protect from light, and let stand until ppt coagulates. Filter on weighed gooch, previously heated to 140–150°, and wash with hot  $\text{H}_2\text{O}$ , testing filtrate to prove excess of  $\text{AgNO}_3$ . Dry  $\text{AgCl}$  at 140–150°, cool, and weigh. Calc. % Cl and DDT as in (a).

### Infrared Method (68)

(Caution: See 51.041.)

## 6.257

### Reagent

*DDT std soln*.—Weigh 0.250 g tech. DDT into 50 mL vol. flask or g-s container and add exactly 25 mL  $\text{CS}_2$ . If sample to be analyzed contains S, add wt of S expected in portion of

sample to be taken for analysis. Shake to dissolve and add small amt anhyd.  $\text{Na}_2\text{SO}_4$ . Centrf. portion of soln if it is not clear.

**6.258****Determination**

Weigh sample contg ca 0.25 g DDT into 50 mL vol. flask and add exactly 25 mL  $\text{CS}_2$  and small amt anhyd.  $\text{Na}_2\text{SO}_4$ . Let stand  $\geq 30$  min with occasional shaking. Transfer portion to g-s test tube and centrf. short time. Transfer to NaCl cell and scan with infrared spectrophtr, using 0.5 mm cell in region, 8.5–10.5  $\mu\text{m}$ .

Scan std soln in same manner.

Measure *A* of DDT peak at 9.83  $\mu\text{m}$  with baseline from 9.4 to 10.2  $\mu\text{m}$ , and calc. % DDT.

**Dimethyl 2,3,5,6-Tetrachloroterephthalate  
(Dacthal) (69)—Official Final Action**

(Caution: See 51.011, 51.018, 51.039, 51.040, 51.041, 51.045, 51.046, and 51.048.)

**Gas Chromatographic Method**

(Under conditions specified, other pesticides or ingredients may interfere with GLC analysis, e.g., aldrin has same retention time as Dacthal. Aldrin and Dacthal may be sepd at 170° column temp.)

**6.259****Apparatus**

*Gas chromatograph.*—1.8 m (6')  $\times$  1/8" id stainless steel column contg 10% silicone UC-98 (Applied Science Laboratories, Inc.) on 80–100 mesh silanized Diatoport S (Hewlett-Packard Co., Rt 41, Avondale, PA 19311). Conditions (applicable to Hewlett-Packard F&M Model 5750)—temps(°): column 200, injection port 240, flame ionization detector 260; H, air, and He carrier flows, 115, 600, and 25 mL/min, resp.; chart speed 0.25"/min; attenuation 4 $\times$ ; range setting 10<sup>2</sup> (10<sup>-10</sup> amp full scale).

**6.260****Preparation of Standard Curve**

(a) *Dacthal std solns.*—Weigh 0.5 g Dacthal (available from Diamond Shamrock Corp., PO Box 348, Painesville, OH 44077) into 100 mL vol. flask, add ca 90 mL acetone (soln is rapid), and dil. to vol. Pipet 5, 10, and 15 mL into sep. 25 mL vol. flasks and dil. to vol. with acetone.

(b) *Hexachlorobenzene (HCB) std solns.*—Weigh 0.5 g ref. grade HCB into 100 mL vol. flask, add 90 mL benzene, and dil. to vol. with benzene. Pipet 1, 2, and 3 mL into sep. 25 mL vol. flasks and evap. to dryness with current of dry air. Add 20 mL acetone to each flask and dil. to vol. with acetone.

Inject 5  $\mu\text{L}$  each dild HCB and Dacthal std at least twice. Prep. curve of peak area or ht against concn for Dacthal and peak ht against concn for HCB.

**6.261****Determination**

(a) *Benzene extraction.*—Grind granular product. Weigh portion contg ca 300–400 mg Dacthal into Whatman extn thimble (33  $\times$  88 mm). Cover with glass wool. Place thimble in medium Soxhlet extractor; add 150–175 mL benzene and 3 glass beads. Ext 6 hr. Quant. transfer ext to 400 mL beaker and evap. to ca 5 mL on steam bath with dry air current; remove and evap. to dryness with air current. Add ca 150 mL acetone and let stand until soln is complete (white, flaky crystals may indicate incomplete soln; soln may be hastened by placing flask in ultrasonic cleaner). Filter soln thru glass wool into 200 mL vol. flask. Wash beaker with acetone, transfer washings to vol. flask, and dil. to vol.

(b) *Alternative acetone extraction.*—Substitute acetone for

benzene in extn. Proceed as in (a) thru "Ext 6 hr." Continue with "Filter soln thru glass wool..."

Inject duplicate 5  $\mu\text{L}$  sample soln into gas chromatograph. Compare peak ht or peak area to std curve to det. % hexachlorobenzene (HCB) and Dacthal.

**Infrared Method****6.262****Preparation of Sample**

Grind granular product. Weigh sample contg 200–500 mg Dacthal into Whatman extn thimble. Proceed as in 6.261(a) thru "... evap. to dryness with air current." Add 25 mL  $\text{CS}_2$ , allow ca 30 min for complete soln, and transfer quant. to 50 mL vol. flask with  $\text{CS}_2$ , filtering sample thru glass wool. Dil. to vol.

**6.263****Preparation of Standard Solution**

Weigh 1.25 g Dacthal into 100 mL vol. flask. Add ca 90 mL  $\text{CS}_2$  (soln may be hastened by placing flask in ultrasonic cleaner) and dil. to vol. Pipet 10, 15, and 20 mL into sep. 25 mL vol. flasks and dil. to vol.

**6.264****Determination**

Set spectrophtr at optimum operating condition. Use 0.5 mm KBr (or NaCl) matched cells. Fill ref. cell with  $\text{CS}_2$ . Transfer dild stds to other cell and scan slowly from 1100 to 900  $\text{cm}^{-1}$ . Repeat with samples. Construct baseline from 1030 to 925  $\text{cm}^{-1}$  and draw line from midpoint of max. *A* at ca 964  $\text{cm}^{-1}$  to intersect baseline. Compute  $\Delta A$  at 964  $\text{cm}^{-1}$  at point of intersection of stds and sample.

Prep.  $\Delta A$ -concn curve for std; Beer's law is obeyed over concn range 2–15 mg Dacthal/mL. Calc. % Dacthal from std curve.

**Dicamba (3,6-Dichloro-*o*-anisic Acid; 2-Methoxy-3,6-dichlorobenzoic Acid) (70)—Official Final Action**

**6.265****Reagents and Apparatus**

(a) *Acetone.*—Spectral grade.

(b) *Dimethylamine (DMA) soln.*—60% (w/w).

(c) *Dicamba std.*—Ref. grade (Velsicol Chemical Corp.).

(d) *Infrared spectrophotometer.*—With  $\text{BaF}_2$  cells, 0.025 mm, and matched NaCl cells, 0.2 mm.

**6.266****Preparation of Sample**

(Sample wts are for cell thicknesses specified. For other cells, adjust wts to yield peak between 30 and 60% *T*.)

(a) *Aqueous solns of DMA salt (4 lb/gal.).*—Pipet, using same pipet as for std, 5.00 mL sample into tared 25 mL vol. flask and weigh. Dil. to vol. with acetone. (Use this soln directly in 0.025 mm  $\text{BaF}_2$  cell.)

(b) *Solns of DMA salt (other concentrations).*—Prep. as in (a), adjusting sample size to yield 2.4 g dicamba/25 mL.

(c) *Technical dicamba.*—Weigh 0.2  $\pm$  0.005 g sample into tared 25 mL vol. flask and dil. to vol. with  $\text{CS}_2$ .

**6.267****Preparation of Standard**

(a) *Liquid formulations.*—(1) *Aqueous solns of DMA salt (4 lb/gal.).* Weigh 11.98  $\pm$  0.02 g dicamba std into tared 50 mL beaker. Add 5 mL  $\text{H}_2\text{O}$  and 4 mL 60% DMA. Adjust pH to 7.0 by titrg with 60% DMA soln, using mag. stirrer and pH meter. (All solids should be dissolved at this time.) Rinse each pH electrode with two 1 mL  $\text{H}_2\text{O}$  rinses (4 mL total), collecting rinses in the 50 mL beaker. Cool soln to room temp. and transfer to tared 25 mL vol. flask. Rinse beaker twice with  $\text{H}_2\text{O}$ , collecting rinses in

flask. Dil. to vol. with H<sub>2</sub>O and mix thoroly. Weigh flask and contents to det. total wt of soln. Pipet 5.0 mL std formulation into tared 25 mL vol. flask, weigh, and dil. to vol. with acetone.

(2) *Aqueous solns of DMA salt (other concentrations)*: Prep. as in (a)(1), adjusting dicamba content to required concn.

(b) *Technical dicamba*.—Weigh  $0.2 \pm 0.005$  g dicamba std into tared 25 mL vol. flask and dil. to vol. with CS<sub>2</sub>.

## 6.268

**Determination**

(a) *Liquid formulations*.—Record spectra of std and sample between 1070 and 930 cm<sup>-1</sup> (9.3–10.7 μm), using BaF<sub>2</sub> cell. Use air in ref. beam. Obtain ΔA and ΔA' for sample and std, resp., at 1012 cm<sup>-1</sup> (9.89 μm) from horizontal baseline tangent to min. between 1020 and 1070 cm<sup>-1</sup> (9.4–9.7 μm).

(b) *Technical dicamba*.—Record spectra of std and sample from 1100 to 930 cm<sup>-1</sup> (9.1–10.7 μm), using NaCl cells. Use CS<sub>2</sub> in ref. cell. Obtain ΔA and ΔA' for sample and std, resp., at 1012 cm<sup>-1</sup> (9.89 μm) from horizontal baseline tangent to min. between 1075 and 1035 cm<sup>-1</sup> (9.3–9.66 μm).

## 6.269

**Calculations**

(a) *Liquid formulations*.—Dicamba, lb/gal. =  $\Delta A \times C / \Delta A'$ , where C = lb std/gal. = (g std × % purity of std × 8.35)/25.

% Dicamba by wt =  $(\Delta A \times F) / (g \text{ sample} / 25 \text{ mL})$ , where F = [(g std/25 mL) × % purity of std]/ΔA'.

(b) *Technical dicamba*.—% Dicamba by wt =  $\Delta A \times F / g \text{ sample}$ , where F = (g std × % purity of std)/ΔA'.

**Dicamba-2-Methyl-4-chlorophenoxyacetic Acid (MCPA)  
and Dicamba-2,4-D (71)—Official Final Action**

**AOAC-CIPAC Method**

(Caution: See 51.041.)

## 6.270

**Principle**

Method is applicable to aq. dimethylamine (DMA) salt formulations of dicamba and 2-methyl-4-chlorophenoxyacetic acid (MCPA) or 2,4-D (2,4-dichlorophenoxyacetic acid). Active ingredients are pptd by HCl and extd with CHCl<sub>3</sub>. Solv. is evapd, residue dissolved in acetone, and A measured at characteristic IR wavelengths.

## 6.271

**Preparation of Standard Solutions**

(a) *Dicamba-MCPA*.—Accurately weigh  $0.20 \pm 0.02$  g dicamba and  $0.60 \pm 0.02$  g MCPA into tared weighing bottle. Pipet in 25 mL acetone and swirl until completely dissolved. If cells other than 0.2 mm are used, adjust wts to give A of 0.2–0.5 (30–65% T) for both std and sample solns.

(b) *Dicamba-2,4-D*.—Prep. as in (a), using  $0.20 \pm 0.02$  g dicamba and  $0.40 \pm 0.02$  g 2,4-D.

## 6.272

**Preparation of Sample**

(a) *Dicamba-MCPA*.—Accurately weigh sample contg  $0.20 \pm 0.02$  g dicamba and  $0.60 \pm 0.02$  g MCPA into tared weighing bottle. Add 5 mL H<sub>2</sub>O and transfer quant. to 125 mL separator with 5–10 mL H<sub>2</sub>O.

(b) *Dicamba-2,4-D*.—Prep. as in (a), using  $0.20 \pm 0.02$  g dicamba and  $0.40 \pm 0.02$  g 2,4-D.

## 6.273

**Determination**

To soln add HCl dropwise with const swirling to pH 1; then add 5 drops excess. Pipet in 25 mL CHCl<sub>3</sub> and shake to dissolve

ppt. Drain CHCl<sub>3</sub> ext into 125 mL erlenmeyer and re-ext with two 15 mL portions CHCl<sub>3</sub>. Add boiling chips to combined ext and evap. on steam bath to dryness. Let dry in hood overnight at room temp. (Do not dry in air or vac. oven.) Pipet in 25 mL acetone and swirl to completely dissolve residue. Add few g granular anhyd. Na<sub>2</sub>SO<sub>4</sub> if any H<sub>2</sub>O is present.

Record IR spectrum and measure ΔA in matched 0.2 mm NaCl cells with acetone in ref. cell at following wavelengths:

(a) *Dicamba-MCPA*.—Range, 1135–930 cm<sup>-1</sup> (8.8–10.75 μm); dicamba peak, 1012 cm<sup>-1</sup> (9.89 μm); MCPA peak, 1070 cm<sup>-1</sup> (9.35 μm); baseline, horizontal tangent to min. at 970–965 cm<sup>-1</sup> (10.3–10.4 μm) for both constituents.

(b) *Dicamba-2,4-D*.—Range, 1130–945 cm<sup>-1</sup> (8.85–10.6 μm); dicamba peak, 1012 cm<sup>-1</sup> (9.89 μm); 2,4-D peak, 1080 cm<sup>-1</sup> (9.26 μm); baseline, horizontal tangent to min. at 970–960 cm<sup>-1</sup> (10.3–10.4 μm) for both constituents.

## 6.274

**Calculations**

% by wt of constituent =  $(\Delta A / W)(W' \times P / \Delta A')$ , where ΔA and ΔA' = absorbance of constituent in sample and std solns, resp.; W and W' = g constituent in sample and std solns, resp.; and P = % purity of constituent in ref. std.

lb/gal. = % by wt × sp gr × 8.345.

**2,4-D (2,4-Dichlorophenoxyacetic Acid)**

**Automated High Pressure Liquid Chromatographic  
Method (72)—Official First Action**

## 6.275

**Principle**

Esters of 2,4-D are saponified *in situ*; amine salts are converted to H<sub>2</sub>O-sol. K salt of 2,4-D. Ionic 2,4-D is protonated by pH 2.95 CH<sub>3</sub>CN-H<sub>2</sub>O (1+4) eluant, and sepd from all known impurities and *p*-bromophenol internal std on reversed phase bonded microparticulate column. 2,4-D elutes between impurities 2,4- and 2,6-dichlorophenol.

## 6.276

**Apparatus**

(a) *Liquid chromatograph*.—Fitted with 5000 psi pressure gage, 280 nm UV detector, line filter in eluant reservoir, and 10 mv full scale deflection strip chart recorder. Automated sampling system and computing integrator are optional. Typical operating conditions: chart speed, 0.2 cm/min; eluant flow rate, 0.9–3.0 mL/min depending upon psi range of pump; detector sensitivity, 0.64 A unit full scale; temp., ambient; injection valve vol., 10 μL.

(b) *Liquid chromatographic column*.—No. 316 stainless steel, 250 × 4.6 (id) mm, Partisil® 10 μm ODS column with 50 × 4.6 (id) mm Co:Pell ODS pellicular guard column (Nos. 6526-124 and 6561-404, resp., Whatman Inc., 9 Bridewell Pl, Clifton, NJ 07014). Regenerate, if necessary, by pumping CH<sub>3</sub>CN thru column until baseline is stable. Repack first 5 mm of guard and main columns with Co:Pell ODS if peaks begin to "tail".

## 6.277

**Reagents**

(a) *Eluant*.—pH 2.95. CH<sub>3</sub>CN (distd-in-glass)-H<sub>2</sub>O (deionized, 0.4 μm filtered) (1+4) contg NaOH added from (1+1) aq. soln of known normality, 50.033(b), at final vol. concn of 0.3M. Add H<sub>3</sub>PO<sub>4</sub> to adjust pH to 2.95.

(b) *Saponification-internal std soln*.—4 g *p*-Bromophenol/L 0.2N KOH in isopropanol-H<sub>2</sub>O (2+1). Add KOH from (1+1) aq. soln of known normality.

(c) *2,4-D std soln*.—300 mg/25 mL. Accurately weigh ca 300 mg 2,4-D anal. ref. std (99+% isomer pure; available from Dow Chemical Co., Sample Coordinator, 9001 Bldg, Midland, MI 48640), previously dried 15 min at 100°, into 1 or 2 oz glass vial

with polyethylene-lined screw cap. Pipet in 25 mL saponification-internal std soln, and shake to dissolve. Prep. 2,4-D std soln and sample soln, 6.278, at same time, using same pipet.

**6.278****Preparation of Sample**

Accurately weigh sample contg ca 300 mg 2,4-D acid equiv. into 1 or 2 oz glass vial with polyethylene-lined screw cap. Pipet in 25 mL saponification-internal std soln, and shake 15 min, warming ester formulations to 50° several min before shaking. Filter prepd sample thru 9 cm Whatman glass microfiber filter GF/A, or equiv., collecting major portion of aq. phase for chromatography. Adjust isopropanol-H<sub>2</sub>O ratio, if necessary, to obtain complete dissoln of sample; e.g., amine formulations are best prepd with isopropanol-H<sub>2</sub>O (1+1).

**6.279****Determination**

Transfer ca 1 mL portions of samples and stds to automated sampler vials, and cap. Place samples and stds in position, and start automatic sampler. With programmed integrator use following calcn program automatically:

$$\% \text{ 2,4-D} = (R/R') \times (W'/W) \times P,$$

where  $R$  and  $R'$  = peak ht or area ratios of 2,4-D to internal std for sample and std, resp.;  $W'$  = mg 2,4-D in std;  $W$  = mg sample; and  $P$  = % purity of std. If automated sampler and computing integrator are unavailable, inject 10  $\mu$ L samples and stds and perform calcns manually. As check on calibration, place stds in sample sequence at beginning, middle, and end. Periodically confirm linearity by analyzing stds contg 200, 300, and 400 mg 99+% 2,4-D/25 mL saponification-internal std soln. Continuously recycle and mag. stir eluant. Replace eluant after ca 200 injections/L.

**Sodium Salt of Dalapon (2,2-Dichloropropionic Acid) (73)—Official Final Action**

(Caution: See 51.041.)

**6.280****Apparatus**

(a) *Reflux apparatus*.—250 mL erlenmeyer connected thru  $\frac{3}{8}$  25/25 ball joint to reflux condenser.

(b) *Filtering apparatus*.—60 mL, medium porosity fritted glass funnel attached to glass filter bell, 11 cm od, 18 cm high, with bottom gasket and slide valve.

**6.281****Reagents**

(a) *Mercuric-cupric nitrate soln.*—(Caution: See 51.065.) Dissolve 100.0 g yellow HgO and 60 g Cu(NO<sub>3</sub>)<sub>2</sub>·3H<sub>2</sub>O in 500 mL 3.100±0.003*N* HNO<sub>3</sub>, measured from vol. flask, in 1 L vol. flask, dil. to vol. with H<sub>2</sub>O, and filter.

(b) *Potassium iodide soln.*—Dissolve 150 g KI in H<sub>2</sub>O, dil. to 1 L, and neutze to phthln.

**6.282****Determination**

Accurately weigh sample contg 0.11–0.22 g Na salt of 2,2-dichloropropionic acid, transfer to erlenmeyer of reflux app., and add 100 mL Hg-Cu nitrate soln. Add some boiling chips, attach condenser, and reflux 15 min. Cool in H<sub>2</sub>O bath. Filter thru filtering app., washing flask and ppt acid-free with H<sub>2</sub>O from wash bottle. Discard filtrate and washings, and place 250 mL narrow-mouth erlenmeyer in filtering bell.

Add 50 mL KI soln to erlenmeyer to dissolve any remaining ppt, transfer to funnel, and stir until ppt dissolves. Draw soln into narrow-mouth erlenmeyer with vac. Wash flask and funnel with  $\leq$ 50 mL KI soln from wash bottle, adding washings to

filtrate. Add few boiling chips to filtrate and boil 1 min. Cool in H<sub>2</sub>O bath. Titr. immediately with 0.1*N* HCl, using phthln.

% Na salt 2,2-dichloropropionic acid = mL 0.1*N* HCl  $\times$  0.004499  $\times$  100/g sample.

**Dicofol (Kelthane®, 4,4'-Dichloro- $\alpha$ -(trichloromethyl)-benzhydrol)**

**Potentiometric Method (74)—Official First Action****6.283****Principle**

Dicofol is hydrolyzed in alc. KOH under reflux, and hydrolyzable org. Cl is converted to ionizable Cl which is titrd potentiometrically with std AgNO<sub>3</sub>.

**6.284****Apparatus**

(a) *Condenser*.— $\frac{3}{8}$  24/40 Pyrex condenser, water cooled, 400 mm long with drip tip.

(b) *Potentiometer*.—Fisher Accumet Model 320 (new model 325) expanded scale pH meter, or equiv., with 50 mL buret graduated in 0.1 mL, Ag billet indicating electrode (Fisher No. 13-639-122), and Ag-AgCl ref. electrode (Fisher No. 13-639-53). Keep Ag electrode free from tarnish by polishing with aq. NaHCO<sub>3</sub>-CaCO<sub>3</sub> (1+1) paste. Before each analysis, rinse Ag electrode with NH<sub>4</sub>OH (1+1) followed by H<sub>2</sub>O.

**6.285****Reagents**

(Use deionized H<sub>2</sub>O thruout.)

(a) *Alcoholic potassium hydroxide soln.*—0.5*N*. Dissolve 28.1 g KOH pellets in ca 600 mL alcohol and dil. to 1 L with alcohol.

(b) *Potassium chloride std soln.*—0.1*N*. Dissolve 7.456 g KCl in H<sub>2</sub>O and dil. to 1 L with H<sub>2</sub>O.

(c) *Silver nitrate std soln.*—0.1*N*. Dissolve 17.00 g AgNO<sub>3</sub> in 100 mL H<sub>2</sub>O, add 1.7 mL HNO<sub>3</sub>, and dil. to 1 L with H<sub>2</sub>O. To stdze, dil. 25 mL 0.1*N* KCl to 200 mL with H<sub>2</sub>O in 400 mL beaker. Adjust pH to 2.0±0.2, using NH<sub>4</sub>OH (1+4) and/or HNO<sub>3</sub> (1+4), and dil. to 300 mL. Titr., using potentiometer as in 6.288. Plot mv against vol. 0.1*N* KCl and det. mL 0.1*N* AgNO<sub>3</sub> at end point. Calc. normality of AgNO<sub>3</sub> std soln. Stdze AgNO<sub>3</sub> std soln daily. (Equiv. wt dicofol = 370.5/3 = 123.5.)

(d) *Thymol blue indicator soln.*—0.1%. Dissolve 100 mg thymol blue in 100 mL alcohol (1+1).

**6.286****Preparation of Sample**

(a) *Kelthane technical*.—Fuse sample in loosely capped jar in 100° oven and mix thoroly with glass rod. Accurately weigh ca 4–6 g molten sample into 150 mL beaker. Add 50–75 mL isopropanol and heat with occasional swirling until sample dissolves. Transfer quant. to 500 mL vol. flask, let cool to 25°, and dil. to vol. with isopropanol. Pipet 25 mL sample soln into 300 mL  $\frac{3}{8}$  24/40 Pyrex erlenmeyer. (Caution: See 51.018.)

(b) *Kelthane formulations*.—(1) *Kelthane MF and Kelthane 35*.—Accurately weigh ca 1 g sample into 300 mL  $\frac{3}{8}$  24/40 Pyrex erlenmeyer. (2) *Kelthane EC*.—Proceed as in (1), using ca 2 g sample.

**6.287****Hydrolysis**

Transfer 50 mL alc. KOH soln to erlenmeyer contg sample. Attach condenser, seal with 2–3 drops alcohol, and reflux gently on hot plate 1.5 hr. Let cool, and rinse condenser and tip with 25 mL alcohol. Quant. transfer soln to 400 mL beaker, using 50 mL alcohol and 100 mL H<sub>2</sub>O. Rinse erlenmeyer with addnl portions H<sub>2</sub>O to total vol. of 250 mL.

Add 10 drops thymol blue indicator soln to beaker and, with

stirring, add  $\text{HNO}_3$  (1+1) dropwise to first pink color of indicator. Adjust pH to  $2 \pm 0.2$ , using  $\text{NH}_4\text{OH}$  (1+4) and/or  $\text{HNO}_3$  (1+4). Adjust total vol. to 300 mL with  $\text{H}_2\text{O}$ .

**6.288****Determination**

Place sample beaker on mag. stirrer, and adjust to rapid stirring. Titr. with  $\text{AgNO}_3$  std soln to same mv end point used for stdzg  $\text{AgNO}_3$  std soln. Titr. blank (unhydrolyzed sample).

% Active ingredient in tech. Kelthane =

$$\{[(V_s/S_a) - (V_b/S_b)] \times N \times V_t \times 0.1235 \times 100\}/V;$$

% Active ingredient in Kelthane formulations =

$$[(V_s/S_a) - (V_b/S_b)] \times N \times 0.1235 \times 100,$$

where  $V_s$  and  $V_b$  = mL  $\text{AgNO}_3$  std soln required to titr. sample and blank, resp.;  $N$  = normality of  $\text{AgNO}_3$  std soln;  $S_a$  and  $S_b$  = g sample taken for hydrolysis and blank, resp.;  $V_t$  = total vol. sample soln = 500 mL; and  $V$  = aliquot vol. sample soln = 25 mL.

**Fluometuron (1,1-Dimethyl-3-( $\alpha,\alpha,\alpha$ -trifluoro-*m*-tolyl)urea)****Gas Chromatographic Method (75)—Official Final Action****6.289****Standard Solutions**

(a) *Diethyl phthalate internal std soln.*—Weigh  $1.5 \pm 0.1$  g tech. diethyl phthalate, dissolve in ca 100 mL alcohol-free  $\text{CHCl}_3$ , dil. to 250.0 mL with  $\text{CHCl}_3$ , and mix well. Std should be >98% pure and contain no impurities eluting at retention time of fluometuron.

(b) *Fluometuron std soln.*—Accurately weigh ca 125 mg tech. fluometuron of known purity (available from Ciba-Geigy Corp., PO Box 11422, Greensboro, NC 27409) into 2 oz round bottle with Teflon-lined or Poly-Seal screw cap. Pipet in 25 mL diethyl phthalate internal std soln and shake to dissolve. Pipet in 3 mL trifluoroacetic anhydride and shake mech. 15 min; then place bottle in  $55^\circ \text{H}_2\text{O}$  bath 30 min. Let cool to room temp.

**6.290****Preparation of Sample**

Accurately weigh sample contg ca 125 mg fluometuron into 2 oz round bottle with Teflon-lined or Poly-Seal screw cap. Pipet in 25 mL diethyl phthalate internal std soln and shake well. Pipet in 3 mL trifluoroacetic anhydride and shake mech. 15 min; then place bottle in  $55^\circ \text{H}_2\text{O}$  bath 30 min. Let cool to room temp. Let insol. materials settle or centr. portion of ext to obtain clear soln.

**6.291****Gas Chromatography**

Use instrument equipped with flame ionization detector and 1.83 m  $\times$  2 (id) mm glass column packed with 2% OV-3 (Applied Science Laboratories, Inc.) on 80–100 mesh Gas-Chrom Q. Condition 24 hr at  $240^\circ$  with N or He at ca 40 mL/min. Column should have  $\geq 1500$  theoretical plates. Use on-column injection to prevent decomposition of derivative.

Typical operating conditions: temps ( $^\circ$ )—inlet 150, column  $115 \pm 10$ , detector 250; N or He carrier gas, 20–22 mL/min; air and H as specified by manufacturer; attenuation varied so that peak hts of pesticide and internal std are 60–80% full scale. Retention times for fluometuron derivative and diethyl phthalate are 3–5 and 8–10 min, resp.

**6.292****Determination**

Proceed as in 6.433–6.434, except inject 1  $\mu\text{L}$  aliquots.

**6.293****Calculations**

See 6.435.

**Folpet (N-(Trichloromethylthio)phthalimide)****High Pressure Liquid Chromatographic Method (76)****AOAC-CIPAC Method—Official Final Action**

(Applicable to dry formulations contg folpet as only active ingredient and to folpet combination formulations except those contg propargite or Me parathion. Compds insol. in  $\text{CH}_2\text{Cl}_2$ , e.g., maneb or inorg. salts, do not interfere.)

**6.294****Apparatus**

(a) *Liquid chromatograph.*—Equipped with 254 nm UV detector. Typical operating conditions: chart speed, 0.2"/min; eluant flow rate, 2 mL/min (ca 800 psi); detector sensitivity, 0.16 A unit full scale; temp., ambient; valve injection vol., 20  $\mu\text{L}$ . Adjust operating conditions to elute folpet peak in  $4 \pm 1$  min. Factors such as different  $\text{H}_2\text{O}$  content in  $\text{CH}_2\text{Cl}_2$  eluant can change retention times. Folpet peak must be completely resolved from dibutyl phthalate peak which normally elutes in ca 7 min.

(b) *Liquid chromatographic column.*—Stainless steel, 300  $\times$  4 (id) mm, packed with 10  $\mu\text{m}$  diam. silica gel particles (Waters Associates, Inc., No. 27477, or equiv.).

**6.295****Reagents**

(a) *Eluant.*—Degassed  $\text{CH}_2\text{Cl}_2$ .

(b) *Internal std soln.*—Accurately weigh ca 0.5 g dibutyl phthalate (MC/B Manufacturing Chemists) into 200 mL vol. flask. Dil. to vol. with  $\text{CH}_2\text{Cl}_2$  and mix.

(c) *Folpet std soln.*—(100  $\mu\text{g}$  folpet + 250  $\mu\text{g}$  dibutyl phthalate)/mL. Accurately weigh ca 20 mg folpet ref. std, 99+ % pure (Chevron Chemical Co., 940 Hensley St, Richmond, CA 94804) into glass vial, pipet 20 mL internal std soln into vial, and shake to dissolve. Pipet 1 mL into 10 mL vol. flask. Dil. to vol. with  $\text{CH}_2\text{Cl}_2$ .

**6.296****Preparation of Sample**

Accurately weigh sample contg 20 mg folpet into vial. Pipet 20 mL internal std soln into vial and shake 30 min. Centr. to ppt solids. Pipet 1 mL supernate into 10 mL vol. flask, dil. to vol. with  $\text{CH}_2\text{Cl}_2$ , and mix. Sample contains ca (100  $\mu\text{g}$  folpet + 250  $\mu\text{g}$  dibutyl phthalate)/mL.

**6.297****Determination**

Inject 20  $\mu\text{L}$  folpet std soln onto column thru sampling valve and adjust operating conditions to give largest possible on-scale peaks with retention time of  $4 \pm 1$  min for folpet. Repeat injections until ratio of folpet to dibutyl phthalate peak hts is within  $\pm 1\%$  of previous injection. Without changing conditions, inject sample soln until its ratio is within  $\pm 1\%$  of previous ratio for sample. Average last 2 peak ht ratios for sample and for std, resp., and calc. % folpet.

$$\% \text{ Folpet} = (R/R') \times (W'/W) \times P,$$

where  $R$  and  $R'$  = av. peak ht ratios for sample and std, resp.;  $W'$  = mg folpet in std soln (ca 20 mg);  $W$  = mg sample extd for analysis; and  $P$  = % purity of std.

**Heptachlor—Official Final Action****Active Chlorine Method (61)****6.298****Reagents**

(a) *Dilute acetic acid.*—80%. Dil. 800 mL HOAc to 1 L with  $\text{H}_2\text{O}$ .

(b) *Silver nitrate-acetic acid std soln.*—Dissolve 17 g  $\text{AgNO}_3$  in 200 mL  $\text{H}_2\text{O}$ , add 56 mL  $\text{HNO}_3$  (1+1), and dil. to 1 L with HOAc. Stdze potentiometrically by adding 25 mL of this soln to

600 mL beaker contg 250 mL 80% HOAc. Immerse glass and Ag electrodes in soln and stir with mag. stirrer. Titr. with 0.1*N* NaCl soln, **6.220(a)**, to end point (max. change in mv/mL NaCl soln). Normality  $\text{AgNO}_3 = \text{mL NaCl} \times \text{normality NaCl} / \text{mL AgNO}_3$ .

**6.299****Preparation of Sample**

(a) *Emulsifiable concentrate formulations*.—Accurately weigh sample contg  $0.3 \pm 0.05$  g heptachlor in 250 mL erlenmeyer. Dissolve in 50 mL HOAc, and pipet in 25 mL 0.1*N*  $\text{AgNO}_3$ , (b). Attach reflux condenser and reflux 1 hr.

(b) *Granular and dust formulations*.—(Caution: See **51.039**, **51.041**, and **51.074**.) Accurately weigh sample contg  $0.3 \pm 0.05$  g heptachlor into 80 × 25 mm Soxhlet extn thimble. Ext 2 hr with pentane and transfer ext to 250 mL erlenmeyer. Attach short reflux column such as 3-ball Snyder or 12" (30 cm) Vigreux to flask and evap. to dryness on steam bath. (Results will be low if reflux column is not used.) Rinse down column with 50 mL HOAc, pipet in 25 mL 0.1*N*  $\text{AgNO}_3$ , (b), attach reflux condenser, and reflux 1 hr.

(c) *Technical*.—Accurately weigh  $0.40 \pm 0.05$  g heptachlor and proceed as in (a).

**6.300****Determination**

Rinse tip of condenser or column with  $\text{H}_2\text{O}$  and cool soln to room temp. Transfer quant. to 600 mL beaker, rinsing with four 10 mL portions 80% HOAc. Immerse glass and Ag electrodes in soln and stir with mag. stirrer. Titr. with 0.1*N* NaCl soln, **6.220(a)**, to end point.

% Heptachlor =  $37.33 \times (25 \times \text{normality AgNO}_3 \text{ soln} - \text{mL NaCl soln} \times \text{normality NaCl soln}) / \text{g sample}$ .

**Gas Chromatographic Method (77)****6.301****Apparatus**

(a) *Gas chromatograph*.—Equipped with H flame ionization detector; capable of accepting glass column and glass-lined sample introduction system or on-column injection. Use following conditions: Temps (°): column 175, detector 175–190, sample inlet 190; N carrier gas pressure 30 psig; recorder chart speed 2.5 cm/min.

(b) *Glass-stoppered tubes*.—Approx. 25 and 75 mL capacity.

(c) *Microliter syringe*.—10  $\mu\text{L}$ , Hamilton Co., 701-N.

**6.302****Reagents**

(a) *Heptachlor*.—Ref. grade (Velsicol Chemical Corp.).

(b) *Aldrin*.—Ref. grade (Velsicol Chemical Corp.).

**6.303****Preparation of Column**

To 9.5 g 100–120 mesh Gas Chrom Q in vac. flask add 0.50 g silicone GE Versilube F-50 (available from Applied Science Labs) dissolved in 50 mL  $\text{CH}_2\text{Cl}_2$ . Shake slurry well to wet solid thoroly. Connect flask to  $\text{H}_2\text{O}$  aspirator and evap. solv. with frequent shaking. When solids appear dry, complete drying by placing flask in steam bath and connecting to vac. pump until ca 4 mm pressure is attained. Remove flask from steam bath and let cool under vac.

Fill 1.5 m (5') ×  $\frac{1}{8}$ " od (0.067" id) Pyrex glass tube with this packing, using vac. pump and gentle tapping. Plug ends of column with glass wool. Condition column 24 hr in 190° oven while purging with N. Let column cool while still purging with N; then install in chromatograph.

**6.304****Preparation of Sample**

(a) *Liquids*.—Weigh sample contg ca 750 mg heptachlor into

75 mL g-s vial and add 500 mg ref. grade aldrin. Add 75 mL fresh  $\text{CS}_2$ , stopper, and shake vigorously 2 min.

(b) *Solids*.—Transfer weighed sample contg ca 750 mg heptachlor to Soxhlet and ext 2 hr with 75 mL pentane. Let cool, add 500 mg ref. grade aldrin to soln, and swirl.

**6.305****Calibration**

Weigh 0.2500 g ref. grade heptachlor and 0.1670 g ref. grade aldrin into 25 mL g-s flask. Dissolve in 25 mL  $\text{CS}_2$ . Chromatograph this soln under conditions given in **6.301(a)** 5 times to obtain accurate response correction factor. (On new column, it is sometimes desirable to inject several 5  $\mu\text{L}$  aliquots of std soln to condition column before use.)

**6.306****Determination**

Let instrument equilibrate as in **6.301(a)**. Inject ca 1  $\mu\text{L}$  sample soln at sensitivity setting such that ht of heptachlor peak is ca  $\frac{1}{4}$  full scale. For each analysis, allow 10–12 min for heptachlor related components to elute. Components and approx. retention times in min are: heptachlor 4.5, aldrin 5.9, chlordene 3.1, and  $\gamma$ -chlordane 9.9.

**6.307****Calculations**

Calc. area of heptachlor and aldrin peaks by multiplying peak ht in mm by width of peak at half ht in mm. Alternatively, use integrator. Calc. response correction factor (*f*, ca 0.82) for each of the 5 std injections as follows:

$f = (\text{area of heptachlor peak} \times \text{mg aldrin} \times \text{purity of aldrin}) / (\text{area of aldrin peak} \times \text{mg heptachlor} \times \text{purity of heptachlor})$ .

Average 5 replicates and use av. to calc. % heptachlor in samples.

% Heptachlor =  $(\text{area of heptachlor peak} \times \text{mg aldrin} \times \text{purity of aldrin} \times 100) / (\text{area of aldrin peak} \times \text{mg sample} \times f)$ .

**Picloram (4-Amino-3,5,6-Trichloropicolinic Acid)  
and 2,4-D (2,4-Dichlorophenoxyacetic Acid)**

**High Pressure Liquid Chromatographic Method (78)  
Official Final Action**

**6.308****Apparatus**

(a) *Liquid chromatograph*.—Equipped with 280 nm UV detector and injection valve. Alternatively, septum injection head may be used; however, stop-flow injection is recommended. Operating conditions: eluant flow rate, 0.7 mL/min (ca 1000 psi); detector sensitivity, 0.08 A unit full scale; temp., ambient, but within  $\pm 2.5^\circ$ .

(b) *Liquid chromatographic column*.—No. 316 stainless steel, 1000 × 2.1 mm id, with Varian No. 96-000075-00 reducing union ( $\frac{1}{8}$ " ×  $\frac{1}{16}$ ") contg 2  $\mu\text{m}$  frit (regular reducing union packed with glass wool may be used instead) packed with DuPont No. 820960005 Zipax® SAX (strong anion exchange) resin. Preclean column with few mL each of  $\text{CHCl}_3$ , acetone, and MeOH, and vac.-dry. Pack in small increments over 40 min period while tapping column on hard surface.

**6.309****Reagents**

(a) *Eluants*.—Prep. sep. solns of 0.01*M*  $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$  (3.8 g/L) and 0.002*M*  $\text{NaClO}_4 \cdot \text{H}_2\text{O}$  (0.28 g/L) in previously boiled and cooled deionized  $\text{H}_2\text{O}$ .

(b) *Salicylic acid internal std soln*.—Accurately weigh ca 3.6 g USP Ref. Std Salicylic Acid into 1 L vol. flask, dil. to vol. with 0.05*N* NaOH in isopropanol- $\text{H}_2\text{O}$  (1+1), and mix.

(c) *Picloram-2,4-D std soln.*—(4 mg picloram + 12 mg 2,4-D + 3.6 mg salicylic acid)/mL. Accurately weigh ca 100 mg picloram ref. std, 99+% pure (Dow Chemical Co.), and ca 300 mg 2,4-D ref. std, 99+% pure (Dow Chemical Co.), into glass vial, pipet in 25 mL salicylic acid internal std soln, and shake to dissolve.

### 6.310 *Preparation of Sample*

Accurately weigh ca 1.6 g sample into ca 10 dram glass vial, pipet in 25 mL salicylic acid internal std soln, and shake to dissolve.

### 6.311 *Determination*

Inject 2  $\mu$ L picloram-2,4-D std soln onto column and adjust attenuation to give largest possible on-scale peaks. Repeat injections until peak ht ratios of herbicide:internal std vary  $\leq 1\%$  for successive injections. Without changing conditions, inject 2  $\mu$ L aliquots sample soln until peak ht ratios vary  $\leq 1\%$ . Average last 2 peak ht ratios for picloram and 2,4-D and calc. % herbicide.

$$\% \text{ Herbicide} = (R_x/R_s) \times (W_s/W_x) \times P,$$

where  $R_x$  and  $R_s$  = av. peak ht ratios of each herbicide to the internal std for sample and std, resp.;  $W_s$  = mg herbicide in std;  $W_x$  = mg sample; and  $P$  = % purity of std.

### Sodium Trichloroacetate (79)—Official Final Action

(Caution: See 51.011, 51.039, 51.041, and 51.070.)

### 6.312 *Apparatus and Reagent*

(a) *Reflux apparatus.*—250 mL erlenmeyer attached thru  $\frac{3}{4}$  24/40 joint to 50 cm water-cooled condenser.

(b) *Dioxane.*—Freshly distd.

### 6.313 *Determination*

Dissolve 25 g sample in  $H_2O$  and dil. to 100.0 mL. Pipet aliquot (usually 10 mL), titrg ca half that of blank, into 250 mL refluxing flask, add 1 drop Me red, and neutze with ca 1N  $H_2SO_4$  to distinct orange-pink. pH is 5.3–5.5; usually  $<0.15$  mL is required. If soln is acid, titr. with ca 1N NaOH. Add 25.00 mL 1N  $H_2SO_4$ , 35 mL dioxane, and few glass beads. Boil vigorously under reflux  $\geq 60$  min. Cool, add 2 drops Me red, and titr. with std 1N NaOH to sharp change from orange to yellow end point. Perform blank detn, omitting sample.

% Na trichloroacetate = Net mL 1N acid  $\times 0.1854 \times 100/g$  sample in aliquot.

### 6.314 Trifluralin—Official First Action

See 6.203–6.214.

## NONHALOGENATED PESTICIDES

### Aldicarb (2-Methyl-2-(methylthio)propionaldehyde-*O*-(methylcarbamoyl) Oxime) (80)—Official Final Action

(Caution: See 51.041.)

### 6.315 *Apparatus and Reagents*

(a) *Infrared spectrophotometer.*—Perkin-Elmer Model 337, or equiv. Adjust conditions as required by specific instrument.

(b) *Soxhlet extractor.*—With 125 mL flask and 25  $\times$  80 mm cellulose thimble.

(c) *Aldicarb std soln.*—0.18 g/100 mL. Accurately weigh (to 0.1 mg) 0.18  $\pm$  0.01 g anal. grade aldicarb (available from Union Carbide Corp., Agricultural Products and Services) into 100 mL g-s vol. flask, add ca 80 mL  $CH_2Cl_2$ , mix to dissolve, and dil. to vol. with  $CH_2Cl_2$ .

### 6.316

### *Determination*

Transfer accurately weighed sample contg 0.18  $\pm$  0.01 g aldicarb to extn thimble, cover with wad of surgical grade cotton, and place thimble in extractor. Add 2–3 Alundum boiling stones and ca 80 mL  $CH_2Cl_2$  to flask, and ext at rate to provide 5 extns within 60 min. Let cool to room temp., transfer quant. to 100 mL g-s vol. flask with  $CH_2Cl_2$ , and dil. to vol.

Using matched 0.5 mm NaCl cells, scan sample and std solns from 5.2 to 6.0  $\mu$ m (1900 to 1600  $cm^{-1}$ ) against  $CH_2Cl_2$ . Calc.  $A$  of sample and  $A'$  of std at 5.75  $\mu$ m (1740  $cm^{-1}$ ), using corresponding  $A$  at 5.4  $\mu$ m (1850  $cm^{-1}$ ) as  $I_0$ . ( $A$  and  $A'$  should both be ca 0.45.)

### 6.317

### *Determination of Binder Correction*

Pipet 50 mL sample soln into 100 mL beaker and place in room temp.  $H_2O$  bath in hood. Evap. to dryness, using gentle stream of clean, dry air. Add 25 mL MeOH, stir well, and filter thru 30 mL coarse fritted glass gooch. Rinse beaker and gooch with 25 mL MeOH, applying vac. until all liq. is in filter flask. Place gooch and contents in original beaker, place 20 mL  $CH_2Cl_2$  in gooch, and swirl to dissolve binder, letting solv. drip into beaker. Repeat with addnl 20 mL  $CH_2Cl_2$ . Quant. transfer solv. to 50 mL g-s vol. flask and dil. to vol. with  $CH_2Cl_2$ . Scan soln as in detn and subtract  $A$  of binder soln (should be  $<0.005$ ) from that of sample ( $=\Delta A$ ).

% Aldicarb by wt =  $(\Delta A/g \text{ sample}) \times (g \text{ std}/A') \times P$ , where  $P$  is % purity of ref. std.

### Amitrole (3-Amino-s-triazole) (81)—Official Final Action

(Caution: See 51.018 and 51.041.)

### 6.318

### *Preparation of Sample Solution*

(a) *50% Dry powder formulation.*—Transfer 10.00 g sample to 100 mL g-s vol. flask, using powder funnel. Add 50 mL DMF. Shake 2–3 min to dissolve amitrole. (Undissolved amitrole is powder and can be differentiated visually from inerts which are usually crystals.) Let settle and carefully decant supernate into 100 mL vol. flask. Repeat extn of residue with three 15 mL portions DMF, letting settle each time before decanting into vol. flask. Dil. combined exts to vol. with DMF and shake well. Filter 40–50 mL thru fritted glass filter of medium porosity. Pipet 25 mL into 400 mL beaker contg 50 mL  $H_2O$ .

(b) *90% Dry powder formulation.*—Dissolve 1.0000 g sample in 100 mL  $H_2O$  in 400 mL beaker.

(c) *Aqueous amitrole.*—Pipet 5 mL sample into 400 mL beaker contg 50 mL  $H_2O$ .

### 6.319

### *Determination*

Adjust sample soln or dild aliquot to pH 1.8 with 0.5N HCl. Stir mech. and titr. with 0.5 mL increments 0.5N NaOH to pH 3.5–4.0. (Use Beckman Model G pH meter, or equiv., equipped with glass-calomel electrode system, and stdzd at pH 4.0 and 7.0 with buffers, 50.007(c) and (d).) Add 0.5N NaOH rapidly to pH 6.5 and then dropwise to pH 7.5 (second inflection point). Plot pH against mL 0.5N NaOH and det. first inflection point (occurs at pH 2.5–2.9).

$$\% \text{ Amitrole by wt} = (B - C) \times 0.5 \times 8.408/F,$$

where  $C$  = mL 0.5*N* NaOH required to titr. to first inflection point;  $B$  = mL 0.5*N* NaOH required to titr. to pH 7.5; and  $F$  = 2.5 for 50% dry powder formulation, (a), g sample for 90% dry powder formulation, (b), and  $5.0 \times$  sp gr sample for aq. amitrole, (c).

lb Amitrole in aq. amitrole/U.S. gal. = % amitrole  $\times$  sp gr  $\times$  8.32/100.

#### Carbaryl (1-Naphthyl Methylcarbamate) (82) Official Final Action

(Caution: See 51.018, 51.040, 51.041, and 51.056.)

##### 6.320

##### Apparatus

- (a) *Centrifuge*.—Clinical model, 8 place, or equiv.
- (b) *Hypodermic syringe*.—1 mL, glass barrel with rubber-tipped plastic plunger (1 mL B-D Glaspak Tuberculin disposable syringe supplied by Becton, Dickinson, and Co. is suitable). Disposable syringe may be used repeatedly. Wash with H<sub>2</sub>O and acetone or MeOH, air-dry, and lubricate rubber plunger tip with silicone stopcock grease.
- (c) *Infrared spectrophotometer*.—Perkin-Elmer Corp., Model 337, or equiv. Operator must adapt conditions to instrument.
- (d) *Rotator*.—Tube type, BBL, or equiv.
- (e) *Shaking machine*.—Wrist-action shaker (Burrell Corp., or equiv.).
- (f) *Tubes*.—Culture tubes, borosilicate glass, 16  $\times$  150 mm with screw caps and Teflon liners (Corning Glass Works No. 9826, or equiv.).

##### 6.321

##### Reagents

- (a) *Methanol-chloroform soln*.—10% (v/v) MeOH in CHCl<sub>3</sub>.
- (b) *Carbaryl std solns*.—(1) 8 mg/mL.—Transfer  $0.12 \pm 0.01$  g carbaryl (anal. grade, available from Union Carbide Corp., Agricultural Products and Services), weighed to nearest 0.1 mg, to culture tube. Pipet 15 mL MeOH-CHCl<sub>3</sub> soln into tube, cap securely, and rotate or shake mech. 30 min. (2) 2.5 mg/mL.—Transfer  $0.25 \pm 0.01$  g carbaryl, weighed to nearest 0.1 mg, to 250 mL g-s erlenmeyer. Pipet 100 mL CHCl<sub>3</sub> into flask, stopper, and swirl to dissolve.

##### 6.322

##### Preparation of Sample

- (a) *Carbaryl dust and powder formulations*.—Transfer weighed sample ( $\leq 2.4$  g) contg  $0.12 \pm 0.01$  g carbaryl to culture tube. Pipet 15 mL MeOH-CHCl<sub>3</sub> soln into tube and cap securely. Rotate or shake mech. 30 min and centr. 10 min.
- (b) *Liquid suspensions*.—Following steps must be performed in order described, as any deviation can cause erroneous results due to faulty sample transfer and incomplete extn: Place ca 20 g Na<sub>2</sub>SO<sub>4</sub> in 250 mL g-s erlenmeyer. Pipet 100 mL CHCl<sub>3</sub> into flask. Vigorously shake sample bottle. Draw appropriate vol. sample into hypodermic syringe without needle. Use ca 0.5 mL sample for carbaryl 4 lb/gal. and ca 1.0 mL for carbaryl 2 lb/gal. Wipe outside of syringe with paper towel and weigh syringe and contents to nearest 0.1 mg. Add sample to erlenmeyer by slowly depressing syringe plunger. Do not let syringe or sample touch sides of flask. Sample must drop into CHCl<sub>3</sub>. Reweigh syringe and calc. sample wt by difference. Stopper flask and shake vigorously 30 min on mech. shaker.

##### 6.323

##### Determination

- (a) *Carbaryl dust and powder formulations*.—Using matched 0.2 mm NaCl cells, scan sample soln against MeOH-CHCl<sub>3</sub> soln from 5.2 to 6.0  $\mu$ m (1900–1600 cm<sup>-1</sup>). Repeat scan with std soln.

Measure  $A$  of carbaryl peak at 5.75  $\mu$ m (1740 cm<sup>-1</sup>), using  $A$  at 5.40  $\mu$ m (1850 cm<sup>-1</sup>) as 0 point.  $A$  = ca 0.4 for both std and sample.

$$\% \text{ Carbaryl by wt} = (A \times B' \times P)/(A' \times B),$$

where  $A$  and  $A'$  = absorbance of sample and std, resp., at 5.75  $\mu$ m;  $B$  and  $B'$  = mg sample and mg std/mL, resp.; and  $P$  = % purity of carbaryl std.

(b) *Liquid suspensions*.—Proceed as in (a), except use matched 0.5 mm NaCl cells and scan sample soln against CHCl<sub>3</sub>.

#### 2,2-Dichlorovinyl Dimethyl Phosphate (DDVP) (83)—Official First Action

##### Method I

(Applicable to sand/sugar base fly bait contg ca 0.5% and 4 lb/gal. DDVP emulsifiable concs. Caution: See 51.041.)

##### 6.324

##### Apparatus and Reagent

- (a) *Infrared spectrophotometer*.—Capable of recording in region 2–15  $\mu$ m. Slit width must be adjustable to give signal-to-noise ratio of ca 100:1; with sealed liq. absorption cell, NaCl windows, and 0.2 mm path length.
- (b) *Hypodermic syringe*.—Luer type, glass, 1.0 mL. Use 18 gage (Stubbs), 2" slip-on needle.
- (c) *2,2-Dichlorovinyl dimethyl phosphate*.—Use std DDVP of known purity. (Available from Shell Chemical Co.)

##### 6.325

##### Calibration of Apparatus

Into each of five 10 mL vol. flasks, weigh, to nearest 0.1 mg, 25, 75, 100, 150, and 200 mg DDVP std, and dil. to vol. with CHCl<sub>3</sub>. Calibration solns contain ca 2.5, 7.5, 10, 15, and 20 g DDVP/L.

Fill sealed liq. absorption cell with CHCl<sub>3</sub>, adjust spectrophtr to optimum settings, and scan over 10.7–9.9  $\mu$ m. Without changing settings, fill cell in turn with each of prepd calibration solns, starting with most dil., and scan each soln over 10.7–9.9  $\mu$ m.

For each scan, construct baseline thru absorption min. at ca 10.0  $\mu$ m parallel to 0 radiation line. Draw perpendicular to 0 radiation line thru absorption max. of calibration soln at ca 10.2  $\mu$ m and measure radiant power  $P_0$  (at 10.0  $\mu$ m) and  $P$  (at 10.2  $\mu$ m), in any convenient units but keeping same units thruout. Calc.  $A$  as  $\log (P_0/P)$ . Repeat calcns, using absorption min. at ca 10.5  $\mu$ m as ref. point.

Subtract  $A$  of cell and CHCl<sub>3</sub> obtained above from  $A$  of cell and calibration solns. Plot  $\Delta A$  of DDVP as ordinate against g/L DDVP as abscissa for each ref. point (10.0 and 10.5  $\mu$ m).

##### 6.326

##### Preparation of Sample Solution

- (a) *Sand/sugar base fly baits*.—Prep. 25  $\times$  400 mm extn column by adding enough diat. earth (Hyflo Super-Cel) to make layer 5 cm high when gently packed. Place 250 mL vol. flask under outlet. Accurately weigh sample contg 0.2–1.0 g DDVP. Transfer sample to extn column with CHCl<sub>3</sub>, and rinse sample container with CHCl<sub>3</sub>.

Working in well-ventilated hood, add 50 mL CHCl<sub>3</sub> to column. Using stirring device, vigorously agitate sample and top half of adsorbent layer to form slurry with solv. Withdraw stirring device, and rinse it and column with addnl CHCl<sub>3</sub> from wash bottle. Let solv. percolate thru column until level is few mm above diat. earth-sample layer.

Add ca 50 mL CHCl<sub>3</sub> to column, agitate sample and diat. earth with stirrer as above, and let solv. percolate thru column until upper level approaches sample layer. Repeat with two addnl 50

mL portions  $\text{CHCl}_3$ . When solv. ht has diminished to 2–3 mm, rinse column with three 10 mL portions  $\text{CHCl}_3$ , letting each portion enter diat. earth layer before adding next. Let column drain and rinse outlet tip with  $\text{CHCl}_3$ , collecting rinse in 250 mL vol. flask.

Transfer  $\text{CHCl}_3$  eluate to evapg dish (125 mm diam.) marked at 40–50 mL. Evap. on steam bath to 40–50 mL. Remove dish and continue evapn at room temp. to 10–15 mL. Using  $\text{CHCl}_3$ , quant. transfer to vol. flask of such size to give DDVP concn of 0.5–1.0 g/100 mL when soln is dild to vol.

(b) *Emulsifiable concentrates*.—Weigh enough sample, to nearest 0.2 mg, to give ca 1 g DDVP/100 mL  $\text{CHCl}_3$  when dild to vol. in 10, 25, or 50 mL vol. flask.

**6.327****Determination**

Dil.  $\text{CHCl}_3$  soln of DDVP to vol. with  $\text{CHCl}_3$ , mix thoroly, and fill calibrated liq. absorption cell with sample soln. Using same instrument settings as for calibration, scan sample soln over 10.7–9.9  $\mu\text{m}$ .

Examine spectra for possible interference and use appropriate absorption min. as ref. point. (If solvs or other ingredients interfere at one of ref. points, use alternative ref. point.) For example,  $\beta$ -naphthol, often used as stabilizer in fly baits, exts with  $\text{CHCl}_3$  and absorbs at ca 10.5  $\mu\text{m}$ , requiring use of 10.0  $\mu\text{m}$  ref. point.

Calc. *A* of sample soln as in 6.325.

From calcd *A*, read g DDVP/L from calibration curve.

% DDVP by wt =  $[(\text{g DDVP/L}) \times \text{mL sample soln}] / (10 \times \text{g sample})$ .

**Method II (84)**

(Applicable to ca 0.5% (w/w) spray soln and ca 1.0% (w/w) cattle spray in hydrocarbon solvs)

**6.328****Apparatus and Reagent**

(a) *Infrared spectrophotometer*.—Double beam instrument with specifications as in 6.324(a).

(b) *2,2-Dichlorovinyl dimethyl phosphate*.—See 6.324(c).

**6.329****Preparation of Compensating Solvent**

Transfer ca 30 mL sample to 125 mL separator and ext (2–3 min per extn) with 4 ca 30 mL portions 0.5*N* NaOH. Dry DDVP-free hydrocarbon phase by passing it thru 2–3 g anhyd.  $\text{Na}_2\text{SO}_4$ . Reserve dried solv. for prepn of DDVP std soln and as compensating solv. in ref. cell.

**6.330****Determination**

Prep. std DDVP soln in compensating solv. that approximates (on wt basis) DDVP content of sample. Calc. DDVP content of std soln to nearest 0.01% by wt.

After detg optimum instrument parameters for compensation technic, scan std soln over 9.9–10.7  $\mu\text{m}$  (1010–935  $\text{cm}^{-1}$ ) region with ref. cell contg compensating solv. in ref. beam of spectrophtr. Scan sample against compensating solv. in same manner.

From differential spectra, det. *A* of DDVP at 10.2  $\mu\text{m}$  (980  $\text{cm}^{-1}$ ) of std, *A'*, and sample, *A*, measured from baseline drawn between minima near 10.0 and 10.6  $\mu\text{m}$ . Calc. DDVP as follows:

% DDVP by wt = % DDVP in std  $\times A/A'$ .

**6.331 Diazinon—Official First Action**

See 6.431–6.435.

**Diquat (6,7-Dihydrodipyrido (1,2-*a*:2',1'-*c*)  
Pyrazinediium Ion) (85)—Official Final Action**

**AOAC-CIPAC Method****6.332****Reagents**

(a) *Acetate buffer soln*.—pH 4.05. Dissolve 10.88 g NaOAc  $\cdot 3\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 19 mL HOAc, dil. to 2 L with  $\text{H}_2\text{O}$ , and mix.

(b) *Diquat std solns*.—(1) *Stock soln*.—0.2 mg diquat/mL. Prep. stock soln by dissolving 0.1968 g pure diquat dibromide monohydrate ( $\text{C}_{12}\text{H}_{12}\text{N}_2\text{Br}_2 \cdot \text{H}_2\text{O}$ , MW 362.1; 50.87% cation; available from Chevron Chemical Co., 940 Hensley St, Richmond, CA 94804) in buffer soln, dil. to 500 mL with buffer soln, and mix. (2) *Working soln*.—0.02 mg diquat/mL. Dil. 10.0 mL stock soln to 100 mL with buffer soln. Prep. dild stds fresh as required.

**6.333****Determination**

Using buret, transfer 10.0, 20.0, and 30.0 mL std diquat soln, contg 0.2, 0.4, and 0.6 mg diquat, resp., to three 100 mL vol. flasks, dil. each soln to vol. with buffer soln, and mix. Measure *A* of stds at 310 nm in 1 cm silica cell, with buffer soln as ref., and draw std curve relating *A* to mg diquat.

Accurately weigh portion (*w* g) of well mixed sample contg ca 0.5 g diquat, transfer to 250 mL vol. flask, dil. to vol. with buffer soln, and mix (*Soln 1*). Transfer 10.0 mL *Soln 1* to 200 mL vol. flask, dil. to vol. with buffer soln, and mix (*Soln 2*). Transfer 5.0 mL *Soln 2* to 100 mL vol. flask, dil. to vol. with buffer soln, and mix (*Soln 3*).

Measure *A* of *Soln 3* at 310 nm in 1 cm silica cell, with buffer soln as ref. Read diquat content of *Soln 3* (*y* mg) directly from std curve or calc. diquat content by interpolation.

% Diquat,  $w/w = 100 y/w$ .

**Paraquat (1,1'-Dimethyl-4,4'-bipyridinium  
Ion) (85)—Official Final Action**

**6.334****Reagents**

(a) *Sodium dithionite*.—1% soln in 0.1*N* NaOH. (Sodium dithionite,  $\text{Na}_2\text{S}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$ , is also called sodium hydrosulfite and sodium hyposulfite.) Do not keep soln >3 hr; solid is unstable in presence of moisture. Store solid in small air-tight bottles in vac. desiccator.

(b) *Paraquat std soln*.—0.25 mg paraquat/mL. Dry anal. std (available from Chevron Chemical Co., 940 Hensley St, Richmond, CA 94804) to const wt at 100–120° before weighing (paraquat salts are hygroscopic). Dissolve 0.1728 g paraquat dichloride (72.40% cation) in  $\text{H}_2\text{O}$ , dil. to 500 mL with  $\text{H}_2\text{O}$ , and mix. Prep. soln fresh as required.

(c) *Extracting soln*.—Dissolve 11 g  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$  in 500 mL  $\text{H}_2\text{O}$ , add 500 mL alcohol, and mix.

**6.335****Preparation of Standard Curve**

Pipet 50 mL std soln into 250 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Pipet 5, 10, 15, and 20 mL aliquots of this dild std soln into sep. 100 mL vol. flasks. (When dild to vol. these solns contain 2.5, 5.0, 7.5, and 10.0  $\mu\text{g}$  paraquat/mL, resp.) Proceed as in 6.337. Plot *A* against  $\mu\text{g}$  paraquat/mL at final diln.

**6.336****Preparation of Sample**

(Caution: Open aerosol can behind safety shield.)

(a) *Formulations not containing oil base*.—Accurately weigh portion well mixed sample contg ca 0.25 g paraquat. Transfer to 500 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix well (*Soln 1*). Pipet 10 mL *Soln 1* into 100 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ ,

and mix well (*Soln 2*). Pipet 10 mL *Soln 2* into 100 mL vol. flask and proceed as in 6.337.

(b) *Aerosol formulations containing oil base.*—Weigh aerosol can to nearest 0.1 g (C). Clamp can with bottom up and puncture smallest possible hole with punch and hammer. After hiss of escaping propellant is no longer heard, cut bottom  $\frac{3}{8}$  open with hand can opener. Push nearly detached lid into can. Immerse can 15 min in 50–70° H<sub>2</sub>O bath or in hot tap H<sub>2</sub>O running into 1 L beaker.

Add 50 mL extg soln, (c), and 50 mL *pentane* to 250 mL separator. Remove can from H<sub>2</sub>O bath, dry well (especially inside cap and around valve), and weigh (D). Place pipet with capacity to deliver ca 20 mg paraquat in can, and weigh both (E). Withdraw liq., transfer contents to separator, replace pipet in can, and weigh (F). (Disregard material left in and on pipet.) Empty can, rinse completely with acetone, air dry, and weigh (G).

Stopper separator and shake 30 sec, venting frequently. Let layers sep, and drain lower layer into 200 mL vol. flask. Add 25 mL extg soln to separator, repeat extn, and drain lower layer into same vol. flask. Dil. to vol. with extg soln and mix well. Pipet 5 mL into 100 mL vol. flask and proceed as in 6.337.

### 6.337

#### Determination

(Complete analysis of one soln before adding dithionite to next soln.)

Add 10 mL Na dithionite soln to one 100 mL vol. flask and dil. to vol. with H<sub>2</sub>O. Mix by inverting end-over-end 3 times at such speed that air bubble travels from one end to other; do *not* shake flask vigorously, as this tends to cause fading of color due to oxidn. Immediately measure *A* of soln at 600 nm, using reagent blank (no paraquat) to set the 100% *T* or for ref. side for dual beam instruments. Similarly, treat each flask in turn, completing color measurement without delay before adding dithionite to next soln.

% Paraquat = ( $\mu\text{g/mL}$  from std curve)  $\times$  5/g sample.

% Paraquat (in aerosol formulations) = [ $\mu\text{g/mL}$  from std curve]  $\times$  (*D* – *G*)  $\times$  0.4 / [(*C* – *G*)  $\times$  (*E* – *F*)].

#### Dithiocarbamates (Ferbam, Maneb, Nabam, Zineb, and Ziram)

(Caution: See 51.041.)

#### Carbon Disulfide Evolution Method (86) Official Final Action

(Applicable only to concs or formulations free from interfering substances)

### 6.338

#### Principle

Dithiocarbamates decompose on heating in acid medium. Evolved CS<sub>2</sub> is passed thru Pb(OAc)<sub>2</sub> soln traps to remove H<sub>2</sub>S and SO<sub>2</sub> formed from sample impurities. Washed CS<sub>2</sub> is reacted with methanolic KOH, and xanthate formed is titrd with I soln.

### 6.339

#### Apparatus

*Carbon disulfide evolution apparatus.*—See Fig. 6:07. Available from Scientific Glass Apparatus Co., No. JE-1000.

### 6.340

#### Reagent

*Methanolic potassium hydroxide.*—2*N*. Dissolve 112 g KOH pellets in 500 mL anhyd. MeOH, filter thru cotton, and add addnl 500 mL anhyd. MeOH.

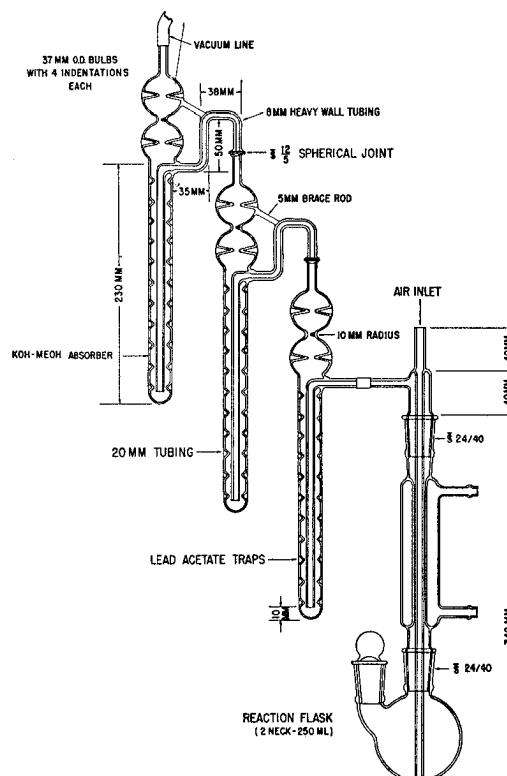

FIG. 6:07—Carbon disulfide evolution apparatus

### 6.341

#### Determination

Add 20 mL 10% Pb(OAc)<sub>2</sub> soln to each Pb(OAc)<sub>2</sub> trap and pipet 50 mL 2*N* MeOH-KOH soln into MeOH-KOH absorber (Fig. 6:07). (Absorber must be dry at time of addn and kept at 25 ± 1°.) Add 50 mL H<sub>2</sub>SO<sub>4</sub> (1+4) to reaction flask and heat acid to boiling. Adjust aspiration rate to ≤ 1 bubble/sec thru MeOH-KOH soln, using stopper in reaction flask.

Weigh ≤ 5 g sample (contg 0.1–0.3 g dithiocarbamates) into small filter paper cone and fold cone to prevent sample loss. Remove stopper from reaction flask, insert wrapped sample, and immediately stopper flask. Adjust air flow if necessary and maintain steady, moderate boil. Do not let acid soln enter air inlet tube. Some dust formulations react vigorously and require special care to prevent ejection of hot acid. As reaction proceeds, adjust system so that rates of boiling and aspiration are almost in equilibrium, producing only very slow rate of bubbling thru MeOH-KOH soln. Continue boiling 1.5 hr. Disconnect MeOH-KOH absorber and rinse contents into 500 mL erlenmeyer, using ca 250 mL H<sub>2</sub>O. (To remove absorber contents, apply slight air pressure to top of absorber and force soln thru side arm. Rinse with 4 ca 25 mL portions H<sub>2</sub>O, forcing out rinse H<sub>2</sub>O in same manner with air pressure.)

Add 3 drops phthln, and titr. with 30% HOAc until red just disappears. Immediately titr. with 0.1*N* I; near end point, add 5 mL starch indicator soln, 6.005(f), and titr. to faint but definite color change.

Det. blank (usually 0.1–0.2 mL 0.1*N* I) by dilg 50 mL MeOH-KOH soln with 250 mL H<sub>2</sub>O, neutzg with 30% HOAc, and titrg as above.

Calc. % dithiocarbamate = (Sample titrn – blank)  $\times$  (I normality)  $\times$  (equiv. wt dithiocarbamate) / (g sample  $\times$  10).

Equiv. wts ( $\frac{1}{2}$  MW) of zineb, maneb, ziram, nabam, and ( $\frac{1}{3}$  MW) ferbam are 137.87, 132.65, 152.91, 128.18, and 138.82, resp.

**Thiram (Bis(dimethylthiocarbamoyl)disulfide)  
(Tetramethylthiuram Disulfide)**

**CIPAC Method (87)—Official Final Action**

**6.342**

**Principle**

Thiram is decomposed by boiling with HOAc and  $\text{Zn}(\text{OAc})_2$  to  $\text{Me}_2\text{NH}$ ,  $\text{CS}_2$ , and carbonyl sulfide. The gaseous mixt. is carried by air stream thru  $\text{CdSO}_4$  scrubber to remove  $\text{H}_2\text{S}$ , and then into absorption system contg MeOH-KOH soln. Mixed xanthate-monothiocarbamate soln is neutrd and titrd with std aq. I.

Method is not specific for thiram. Sep. characterization test, 29.171, must be made.

**6.343**

**Apparatus**

**Assembly and operating conditions.**—Assemble app. as shown in Fig. 6:08 with 30 mL  $\text{CdSO}_4$  soln in first absorber, 25 mL KOH soln in second absorber, and 5 mL in each bubbler. Turn on condenser  $\text{H}_2\text{O}$  and maintain  $\text{H}_2\text{O}$  bath surrounding  $\text{CdSO}_4$  scrubber at 70–80° thruout test. Keep main KOH absorber at <25° by immersion in beaker of cold  $\text{H}_2\text{O}$ . Absorber must be dry or rinsed with MeOH before adding KOH soln. Air bleed must reach nearly to bottom of digestion flask. Make all joints gas-tight, using small amts  $\text{H}_3\text{PO}_4$ , petrolatum, or silicone grease.

Check app. for absorber leaks and efficiency periodically, using pure Na diethyldithiocarbamate. Recoveries should be 99–101%. Check purity of Na diethyldithiocarbamate by dissolving ca 0.5 g, accurately weighed, in 100 mL  $\text{H}_2\text{O}$  and titrg directly with 0.1N I, using ca 2% starch soln as indicator. 1 mL 0.1N I = 0.02253 g Na diethyldithiocarbamate. % Na diethyldithiocarbamate =  $2.253 \times \text{mL } 0.1N \text{ I/g sample}$ .

**6.344**

**Reagents**

- (a) *Acid mixture.*—Dissolve 2.5 g ZnO in 100 mL HOAc (1+1).
- (b) *Cadmium sulfate soln.*—Dissolve 18.5 g  $3\text{CdSO}_4 \cdot 8\text{H}_2\text{O}$  in 100 mL  $\text{H}_2\text{O}$ .
- (c) *Potassium hydroxide soln.*—2N in MeOH and contg <1 ppm Cu or Fe.
- (d) *Iodine std soln.*—0.1N. Stdze as in 50.019.

**6.345**

**Determination**

Accurately weigh and transfer sample contg ca 0.3 g thiram to digestion flask, using small amt  $\text{H}_2\text{O}$ , if necessary. Assemble air bleed and dropping funnel, Fig. 6:08, and add 20 mL acid mixt. thru funnel. Connect app. to controlled aspiration (vac. or compressed air) so that ca 3 bubbles/sec pass thru absorbers. After sample is evenly dispersed, heat and reflux 30 min at moderate rate. Turn off cooling  $\text{H}_2\text{O}$  and flush condenser and first absorber with steam from flask  $\leq 1$  min. Remove burner

and disconnect train. Wash contents of KOH absorber and bubblers into 600 mL beaker with 300–400 mL  $\text{H}_2\text{O}$ , add 1–2 drops phthln, just neutze with HOAc (1+9) from buret, and add 3 drops excess. With continual stirring, titr. immediately (preferably within 1 min, as decomposition of mixed xanthate/monothiocarbamate soln is extremely rapid under acidic conditions) with 0.1N I ( $t$  mL), using ca 2% starch soln as indicator. Det. blank in same manner, omitting sample ( $b$  mL). 1 mL 0.1N I = 0.01202 g thiram.

% Thiram =  $1.202 (t - b)/\text{g sample}$ .

**Dodine (n-Dodecylguanidine acetate) (88)  
Official Final Action**

(Caution: See 51.022, 51.028(a) and (d), and 51.041.)

**6.346**

**Reagents**

(a) *Perchloric acid.*—0.05N. Dissolve 4.2 mL 72%  $\text{HClO}_4$  in HOAc and dil. to 1 L with HOAc. Stdze as follows: Accurately weigh 0.200 g  $\text{KHC}_8\text{H}_4\text{O}_4$  into 250 mL erlenmeyer. Dissolve in 20 mL HOAc by gently heating flask on hot plate. Add 80 mL  $\text{Ac}_2\text{O}$  and 8 drops metanil yellow indicator, (b). Place erlenmeyer contg bar on mag. stirrer and titr. with  $\text{HClO}_4$  to first definite red (magenta). Titr. reagent blank and correct sample titer.

Normality =  $0.200/(0.20422 \times \text{net mL } \text{HClO}_4)$

(b) *Metanil yellow.*—0.20%. Dissolve 0.200 g metanil yellow powder in 100 mL MeOH.

(c) *Potassium acid phthalate.*—NBS SRM  $\text{KHC}_8\text{H}_4\text{O}_4$ .

**6.347**

**Determination**

Accurately weigh sample contg ca 0.600 g dodine into 250 mL erlenmeyer. Add 10 mL HOAc followed by 90 mL  $\text{Ac}_2\text{O}$ . Mix by swirling 5 min. Filter slurry with vac. thru large, medium porosity fritted glass buchner into 250 mL vac. flask. Wash erlenmeyer and residue in funnel with two 10 mL portions HOAc- $\text{Ac}_2\text{O}$  (10+90). Place vac. flask contg bar on mag. stirrer, add 8 drops metanil yellow indicator, and titr. with stdzd ca 0.05N  $\text{HClO}_4$  to first definite red (magenta). Titr. reagent blank and correct sample titer.

% Dodecylguanidine acetate

=  $(\text{net mL } \text{HClO}_4 \times \text{normality} \times 28.75)/\text{g sample}$

**Formaldehyde in Solutions—Official Final Action**

**Hydrogen Peroxide Method (89)**

**6.348**

**Reagents**

(a) *Sulfuric acid std soln.*—1N. Prep. and stdze as in 50.039–50.041.

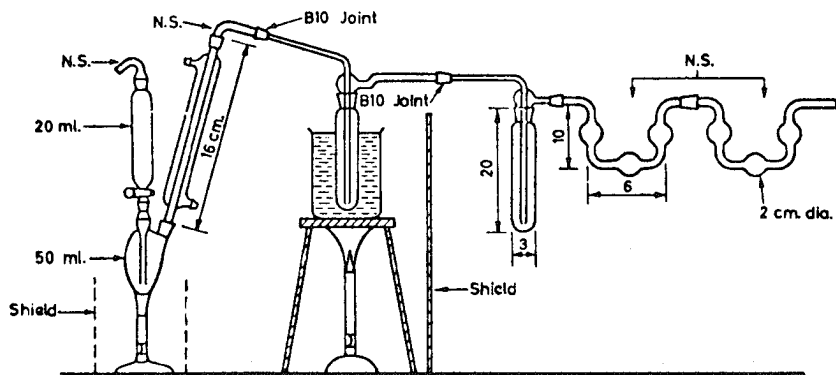

FIG. 6:08—Absorption system for thiram. Dimensions in cm; N.S. = nonstandard; B10 =  $\text{B } 10/30$

(b) *Sodium hydroxide std soln.*—1*N*. Stdze against (a), using litmus or bromothymol blue indicator. 1 mL = 30.03 mg HCHO.

(c) *Hydrogen peroxide soln.*—Com., contg ca 3% H<sub>2</sub>O<sub>2</sub>. If acid, neutze with NaOH, (b), using litmus or bromothymol blue indicator.

(d) *Litmus indicator.*—Soln. of purified litmus of such concn that 3 drops gives distinct blue color to 50 mL H<sub>2</sub>O.

(e) *Bromothymol blue indicator.*—Dissolve 1 g bromothymol blue in 500 mL alcohol, 50% by vol.

### 6.349

#### Determination

Pipet 50 mL 1*N* NaOH soln into 500 mL erlenmeyer and add 50 mL H<sub>2</sub>O<sub>2</sub>, (c). Add weighed amt sample (ca 3 g) from weighing pipet, letting point of pipet reach nearly to liq. in flask. Place funnel in neck of flask and heat on steam bath 5 min, shaking occasionally. Remove from bath, wash funnel with H<sub>2</sub>O, cool to room temp., and titr. excess NaOH with std acid, using bromothymol blue or litmus. (Cool flask before titrn to obtain sharp end point with litmus.) From mL 1*N* NaOH used and wt sample, calc. % HCHO according to following equation

If HCHO soln contains appreciable free acid, titr. sep. portion and calc. acidity as % HCOOH. Correct for this acidity in calcg % HCHO.

### 6.350 Cyanide Method (90)

(Applicable only to dil. solns)

Treat 15 mL 0.1*N* AgNO<sub>3</sub>, **50.027–50.029**, with 6 drops HNO<sub>3</sub> (1+1) in 50 mL vol. flask, add 10 mL KCN soln (3.1 g in 500 mL H<sub>2</sub>O), dil. to vol., shake well, filter thru dry filter, and titr. 25 mL filtrate with 0.1*N* NH<sub>4</sub>SCN, **50.003–50.004**, as in **3.074**. Acidify another 15 mL portion 0.1 *N* AgNO<sub>3</sub> with 6 drops HNO<sub>3</sub> (1+1) and treat with 10 mL of the KCN soln to which has been added measured amt of sample (wt calcd from sp gr) contg ≤25 mg HCHO. Dil. to 50 mL, filter, and titr. 25 mL aliquot with the 0.1*N* NH<sub>4</sub>SCN as before. Difference between mL NH<sub>4</sub>SCN used in these 2 titrns × 2 = mL 0.1*N* NH<sub>4</sub>SCN corresponding to KCN used by the HCHO. Calc. % HCHO present. 1 mL 0.1*N* NH<sub>4</sub>SCN = 3.003 mg HCHO.

### 6.351 Formaldehyde in Seed Disinfectants (97)

#### Official Final Action

(Applicable to detn of HCHO absorbed in inert carrier, e.g., bentonite, talc, charcoal, sawdust)

Weigh ca 5 g sample contg 0.3–0.5 g HCHO in weighing bottle and transfer to 800 mL Kjeldahl flask. Add 25 mL H<sub>2</sub>O and 12 mL H<sub>2</sub>SO<sub>4</sub> (1+4). Steam distil rapidly, passing vapors thru condenser with delivery end dipping into 25 mL H<sub>2</sub>O in 500 mL vol. flask. Collect ca 450 mL distillate, keeping vol. in distg flask nearly const with aid of small flame. After distn, wash delivery tube, and dil. distillate to vol. with H<sub>2</sub>O.

Into each of two 200 mL vol. flasks measure 20 mL 0.1*N* AgNO<sub>3</sub>. To each flask add 12 drops HNO<sub>3</sub> (1+1) and 30 mL H<sub>2</sub>O. To one flask add slowly, with const shaking, 30 mL KCN soln (3.1 g in 1 L H<sub>2</sub>O). Dil. to vol., shake well, and filter thru dry filter. To 100 mL filtrate add 3 mL HNO<sub>3</sub> and 5 mL ferric indicator, **6.019(e)**, and titr. with 0.1*N* KSCN.

Pipet 25 mL HCHO distillate into small beaker contg 30 mL of the KCN soln, mix well, and add slowly, with const shaking, to second flask contg the acidified AgNO<sub>3</sub> soln. Dil. to vol. with H<sub>2</sub>O, filter, acidify 100 mL filtrate with 3 mL HNO<sub>3</sub>, and titr. with the KSCN soln, using FeNH<sub>4</sub>(SO<sub>4</sub>)<sub>2</sub> indicator.

Difference between mL KSCN soln used in these 2 titrns × 2 = mL 0.1*N* KSCN equiv. to HCHO. Calc. % HCHO present. 1 mL 0.1*N* KSCN = 3.003 mg HCHO.

### Ethion (O,O,O',O'-Tetraethyl S,S'-methylene bis-phosphorodithioate)

#### High Performance Liquid Chromatographic Method (92) Official First Action

(Applicable to dry and liquid formulations contg ethion as only active ingredient.)

### 6.352

#### Apparatus

(a) *Liquid chromatograph.*—Waters Associates with Model 6000A pump, or equiv., with 254 nm UV detector (Waters Associates, Inc). Typical operating conditions: eluant flow rate 1 mL/min (ca 1100 psi), chart speed 0.25 in./min, detector sensitivity 0.2 A unit full scale, ambient temp, injection vol. 10 μL. Adjust operating conditions to elute ethion peak in 6±2 min. Column condition and H<sub>2</sub>O content of MeOH eluant can change retention times. Ethion peak must be sepd completely from internal std peak which normally elutes in ca 7 min (Waters C<sub>18</sub> column).

(b) *Liquid chromatographic column.*—Either (1) Waters μBondapak C<sub>18</sub>, 300 × 3.9 mm id; or (2) DuPont ODS Permaphase, 0.5 m × 2.1 mm id.

### 6.353

#### Reagents

(a) *Eluant.*—Either (1) degassed MeOH-H<sub>2</sub>O (90+10), UV cutoff <230 nm, or (2) degassed acetonitrile-H<sub>2</sub>O (40+60), UV cutoff <230 nm.

(b) *Light mineral oil.*—USP, viscosity 38.1 centistokes at 37.8°.

(c) *Internal std soln.*—(1) *For Waters column.*—Accurately weigh ca 0.24 g pentachloronitrobenzene (PCNB), ref. grade, with no interfering peaks on HPLC, into 200 mL vol. flask. Dil. to vol. with MeOH and mix. (2) *For DuPont column.*—Using CH<sub>3</sub>CN as solv., vary amt PCNB in internal std to give peak ht approx. same as ethion peak.

(d) *Ethion std solns.*—(1) *For Waters column.*—*Stock soln.*—Accurately weigh amt of std equiv. to 250 mg ethion, 95+% pure (available from Chemical and Biological Investigations, Environmental Protection Agency, Beltsville, MD 20705) into 25 mL vol. flask, dil. to vol. with MeOH, and mix. *Working soln.*—Pipet 10 mL stock soln into 50 mL vol flask, pipet 10 mL internal std soln, (c)(1), into flask, dil. to vol. with MeOH, and mix. Prep. std and samples daily. (2) *For DuPont column.*—Prep. as above, using CH<sub>3</sub>CN instead of MeOH. (3) *For oil formulations.*—Pipet 10 mL 1% stock soln (1) or (2) into 50 mL vol. flask contg ca same wt of light mineral oil as sample. Add 20 mL MeOH (or CH<sub>3</sub>CN) and proceed as in **6.354(c)** beginning with "Stopper and agitate . . ."

### 6.354

#### Preparation of Sample

(a) *Dry powder.*—Accurately weigh sample contg ca 100 mg ethion into 250 mL g-s flask. Pipet in 40 mL MeOH (or CH<sub>3</sub>CN) and 10 mL internal std soln. Shake 30 min on mech. shaker and centr. to sep. phases.

(b) *Liquid concentrates.*—Prep. sample as in **6.353(d)**.

(c) *Oil formulations.*—Accurately weigh sample contg ca 100 mg ethion into 50 mL vol. flask. Add 30 mL MeOH (or CH<sub>3</sub>CN). Stopper and agitate vigorously 1 min, with side to side action, keeping mixt. in main body of flask. Pipet in 4 mL H<sub>2</sub>O and repeat vigorous mixing 1 min. Dil. to approx. vol. with MeOH (or CH<sub>3</sub>CN). Cool to ambient temp and dil. to vol. Mix thoroly by inverting 10 times and swirling vigorously each time. Centr. to sep. phases.

## 6.355

**Determination**

Use high-pressure liq. syringe or sample injection loop to inject 10  $\mu$ L portions of std until 2 peak ht ratios agree within  $\pm 1\%$ . Alternately inject two 10  $\mu$ L portions each of sample and std solns. Measure peak hts and calc. av. peak ht ratios for both std and sample. Adjust attenuation or amt injected for convenient size peaks (60–80% full scale). Measure peak hts from baseline between ethion and internal std peaks.

$$\% \text{ Ethion} = (R/R') \times (W'/W) \times P,$$

where  $R$  and  $R'$  = av. peak ht ratios for sample and std, resp.;  $W'$  = mg ethion in working std soln (ca 100 mg);  $W$  = mg sample in final diln; and  $P$  = % purity of std.

**Formothion [S-[2-(Formyl methylamino)-2-oxoethyl] O,O-dimethyl phosphorodithioate; O,O-Dimethyl S-(N-formyl-2-mercapto-N-methylacetamide) phosphorodithioate] (93)—Official Final Action**

**CIPAC-AOAC Method**

## 6.356

**Reagents**

- Solvent I.*—Toluene contg 2%  $\text{Ac}_2\text{O}$ .
- Solvent II.*—Hexane-acetone (2+1) plus 2%  $\text{Ac}_2\text{O}$ .
- Internal std soln.*—Prep. soln contg ca 100 mg, accurately weighed, of ethion/mL solv. I. Ethion must be  $>95\%$  pure and contain no impurities interfering at formothion retention time.
- Reference std soln.*—Accurately weigh ca 500 mg Formothion Ref. Std (Sandoz Ltd, Agrochemical Division, CH4002 Basel, Switzerland) into 50 mL vol. flask, add 5.0 mL internal std soln, and dil. to vol. with solv. I.

## 6.357

**Apparatus**

(a) *Gas chromatograph.*—(Varian Aerograph 1520, or equiv.) With flame photometric detector (Tracor, FPD 100AT, or equiv.), automatic injector (Hewlett-Packard 7600 A, or equiv.), integrator (Infotronics CRS 104, or equiv.), and effluent splitter at column end with ratio 1:100–1:1000 in favor of outlet. Use glass spiral column, 1.0 m  $\times$  3.6 mm id, packed with 3% OV 225 on 80–100 mesh Chromosorb W-HP. Operating conditions: temps ( $^{\circ}$ )—oven 210, injector and detector 220; N carrier gas 60 mL/min; no. theoretical plates for ethion is ca 2000. Alternatively, flame ionization may be used. Conditions are same, except effluent splitter is not necessary.

(b) *Bottles.*—50 mL with Mininert valve, or equiv. inert system for closure (Pierce Chemical Co.).

## 6.358

**Determination**

Accurately weigh well mixed sample contg ca 500 mg formothion into bottle, (b). Add 5.0 g internal std soln, (c), and dil. to 50 mL with solv. I. Close tightly and shake. Transfer 6  $\mu$ L soln to vial contg 1 mL solv. II. Seal vial with inert valve system. (For automatic injections with Hewlett-Packard sampler, dil. in Al foil-sealed vials and use Teflon rubber laminated disks as septa.) Keep tightly closed. Inject 1.0  $\mu$ L dild mixt. into column, bypassing solv. around detector by using splitter to avoid contamination and deterioration. Det. appropriate time for splitting by test chromatogram. Compds may be identified by retention times relative to ethion as 1.00 (ca 4.4 min): formothion 0.50, dimethoate (by-product) 0.36.

Inject 1  $\mu$ L aliquots of reference std soln, (d), until ht or area ratio of formothion to ethion varies  $<2\%$  for successive injections. Precede and follow each sample by reference std soln

and make 3 sep. detns with all peak area ratios of reference std solns within  $\pm 2\%$  of first accepted values.

$$\% \text{ Formothion} = W' \times H \times f \times P / W \times H',$$

where  $W$  and  $W'$  = mg sample and internal std, resp.;  $H$  and  $H'$  = peak hts or areas of formothion and internal std, resp.;  $P$  = % formothion in reference compd;

$$f = \text{correction factor} = w \times h' / w' \times h;$$

where  $w$  and  $w'$  = mg formothion ref. std and internal std, resp., and  $h$  and  $h'$  = peak hts or areas of formothion and internal std, resp.

**Malathion (O,O-Dimethyl Dithiophosphate of Diethyl Mercaptosuccinate)**

(Caution: See 51.011 and 51.061.)

**Argentimetric Method (94)—Official First Action**

## 6.359

**Principle**

Malathion is cleaved in alk. soln to dimethyl phosphorodithioate ion which forms insol. ppt with Ag ion. Pos. bias may be encountered.

## 6.360

**Reagents**

- Potassium hydroxide soln.*—1N. Dissolve 28 g KOH in 500 mL alcohol.
- Silver nitrate soln.*—0.1N. Prep. as in 50.027 and stdze against primary NaCl as in 6.363.
- Cellulose powder.*—Reeve Angel No. CF-11.

## 6.361

**Apparatus**

- Potentiometer.*—Recording potentiometric titrator, operated in derivative mode (Metrohm Models E336 thru E576, or equiv.; available from Brinkman Instruments), or pH meter with mv scale.
- Glass reference electrode with Ag/AgCl internal element.*—Corning Glass Works, No. 476022.
- Silver billet electrode.*—Beckman Instruments, No. 39261.
- Chromatographic tube.*—30 cm  $\times$  13.5 mm id.

## 6.362

**Preparation of Samples**

(a) *Technical grade malathion or malathion emulsifiable concentrates.*—Place 2 g cellulose powder in 50 mL beaker, add 0.6 g  $\text{H}_2\text{O}$  dropwise, and mix thoroly. Place plug of glass wool in bottom of chromatgc tube and pack with the wetted cellulose powder. Compress column to 5 cm with glass rod. Wet column with 5 mL hexane.

Accurately weigh sample contg  $0.5 \pm 0.1$  g malathion into 250 mL beaker, add 50 mL hexane, and stir 10 min, using mag. stirrer. Transfer to column and collect eluate in another 250 mL beaker. Rinse original beaker with three 20 mL portions hexane and pour each thru column. Carefully evap. eluate just to dryness. Add 50 mL alcohol or isopropanol and stir mag.; add 20 mL 1N KOH and stir 1 min more. Add 50 mL  $\text{H}_2\text{O}$  and 20 mL 2N  $\text{HNO}_3$ , and stir.

(b) *Powder formulations.*—Accurately weigh sample contg  $0.5 \pm 0.1$  g malathion into 250 mL beaker, add 50 mL hexane, cover with watch glass, and stir mag. 20 min at high speed without splashing. Filter thru fiber glass paper in 4.25 cm buchner and quant. recover filtrate. Thoroly wash beaker and funnel with two 20 mL portions hexane. Quant. transfer filtrate to 250 mL beaker and evap. hexane just to dryness. Add 50 mL alcohol or isopropanol and stir mag.; add 20 mL 1N KOH and stir 1 min more. Add 50 mL  $\text{H}_2\text{O}$  and 20 mL 2N  $\text{HNO}_3$ , and stir.

## 6.363

**Determination**

(a) *pH meter*.—Immerse electrodes in soln and set pH meter to read absolute mv. Titr. with 0.1*N* AgNO<sub>3</sub> soln until meter reads ca 520 mv (within 1–2 mL of end point). Continue titrn by dropwise addn of titrant to end point, 425 mv.

(b) *Recording potentiometric titrator*.—Set instrument in derivative mode and titr. at 2.0±0.2 mL 0.1*N* AgNO<sub>3</sub> soln/min to within ca 2 mL of expected end point. Decrease rate to 0.7±0.1 mL/min and continue titrn. Take first inflection in titrn curve as end point.

$$\% \text{ Malathion} = (V \times N \times 33.04)/W,$$

where *V* = mL AgNO<sub>3</sub> soln, *N* = normality of AgNO<sub>3</sub> soln, and *W* = g sample.

**Colorimetric Method (95)—Official First Action**

(Caution: See 51.018, 51.040, 51.041, 51.043, and 51.051.)

## 6.364

**Principle**

Malathion, *S*-(1,2-dicarbethoxyethyl) *O,O*-dimethyl phosphorodithioate, is decomposed by alkali in alcohol to Na *O,O*-dimethyl phosphorodithioate (NaDMTA), Na fumarate, and alcohol. NaDMTA is converted to Cu<sup>+2</sup> complex sol. in cyclohexane with formation of intense yellow compd whose intensity is proportional to concn of *O,O*-dimethyl phosphorodithioic acid and which is measured colorimetrically at 420 nm. Pos. bias may be encountered.

## 6.365

**Precautions**

Vol. of nonaq. solns is highly temp. dependent. Maintain all reagents at uniform temp.

All glassware must be clean and dry. Rinse tubes and pipets with MeOH and oven dry before use. After use, rinse all glassware in contact with Cu reagent with acetone before washing to prevent contamination in future analyses. If difficulties are still encountered, use 1% HCl in MeOH as wash prior to oven drying.

Det. *A* of blank against H<sub>2</sub>O whenever new reagents are prepd. Deviation from range 0.010–0.020 *A* units, using 1 cm cells, indicates either contamination of glassware or reagents, or reagents of improper concn.

## 6.366

**Reagents**

(a) *Cyclohexane*.—Pass thru column of activated silica gel or Al<sub>2</sub>O<sub>3</sub>, activity grade I. Accuracy of assay depends on stability of Cu complex which undergoes oxidn-reduction reaction catalyzed by strong proton donors. Net result is fading of developed color. Polar impurities in cyclohexane contribute to this problem and quality of solv. must be checked as follows before continuing with analysis: Perform detn, 6.368, with std soln (b)(1) or (2) and det. *A* at 2 min and again at 12 min. Calc. fade rate (*FR*) as follows:

$$FR = [(A_{2 \text{ min}} - A_{12 \text{ min}}) \times 100]/[A_{2 \text{ min}} \times 10]$$

Fade rate should be ≤0.5%/min for std or samples. If fade rate exceeds that limit, pass cyclohexane thru silica gel or Al<sub>2</sub>O<sub>3</sub> column contg ca 100 g adsorbent/2 L cyclohexane to be treated. Ratio of ht of adsorbent bed to its diam. should be >5 and flow should be ≤3 mL/min. Retest cyclohexane after treatment to det. its acceptability. Vol. of cyclohexane that can be treated in this manner will depend on extent of contamination. Check purity periodically.

(b) *Analytical stds*.—Use either malathion or KDMTA, anal. grade of known purity (available from American Cyanamid Co.),

for std soln. Use of malathion will provide assurance that quant. elimination reaction is taking place. Store malathion in refrigerator, warming to room temp. before use. Store KDMTA in desiccator, avoiding elevated temp.

(1) *Malathion std solns*.—Accurately weigh 130–170 mg malathion into tared 50 mL vol. flask. Dissolve in and dil. to vol. with cyclohexane. Store in refrigerator; use at room temp. (2) *Potassium O,O-dimethyl phosphorodithioate (KDMTA) std solns*.—Accurately weigh 80–120 mg KDMTA into tared 50 mL vol. flask. Dissolve in and dil. to vol. with acetone. Mix. Store in tightly stoppered flask.

(c) *Copper reagent*.—Dissolve 410–430 mg cupric naphthenate (ICN–K&K Laboratories, Inc., No. 8172) or 8% Cu Nap-All liq. (Mooney Chemicals Inc., 2301 Scranton Rd, Cleveland, OH 44113) in 100 mL cyclohexane.

(d) *Ethyl acetate*.—Contg ≤0.2% H<sub>2</sub>O and with acidity ≤0.005% expressed as HOAc.

(e) *Sodium hydroxide soln*.—1*N*. Dissolve 4 g carbonate-free NaOH in 100 mL absolute alcohol or absolute ethanol denatured with 0.5% benzene.

(f) *Acetonitrile*.—Bp 80–82°. Pass thru column of silica gel, discarding yellow first portions of eluate and collecting colorless eluate. pH of 10% aq. soln should be 5–7.

## 6.367

**Preparation of Sample**

(a) *Technical materials and emulsifiable concentrates*.—Accurately weigh sample contg 130–170 mg malathion into tared 50 mL vol. flask. Dissolve in and dil. to vol. with cyclohexane. Stopper flask and mix well.

(b) *Wettable powders and dusts*.—Accurately weigh sample contg 130–170 mg malathion on tared weighing paper. Transfer to 8 oz narrow-mouth bottle fitted with Vinylite-lined screw caps. Add 100 mL cyclohexane or acetone, using vol. flask. Place sample 10 min on reciprocating shaker set for moderate agitation. Let solids settle or centr., if necessary. Alternatively, use 150 mL g-s erlenmeyer and mag. stirrer.

Cyclohexane will not quant. ext malathion from powders formulated with bentonite (montmorillonite, Al<sub>2</sub>(Si<sub>4</sub>O<sub>10</sub>)(OH)<sub>2</sub>), and possibly with other carriers. In these cases, ext malathion with CH<sub>3</sub>CN or tetrahydrofuran. If CH<sub>3</sub>CN is used, evap. ext to dryness in rotary evaporator under vac. at ≤50°. Similarly evap. appropriate vol. CH<sub>3</sub>CN for reagent blank. Carefully dissolve residue in cyclohexane and proceed with detn. If tetrahydrofuran is used, proceed as directed, incorporating tetrahydrofuran reagent blank. Use alternative extn technics whenever it is not known whether method will give adequate extn.

## 6.368

**Determination**

Pipet 5 mL aliquots from (a) or 10 mL aliquots from (b) and appropriate dild stds to sep. 50 mL vol. flasks. Prep. reagent blanks by transferring 5 or 10 mL aliquots cyclohexane to 50 mL vol. flask. Use acetone in reagent blank if KDMTA is std.

At 1 min intervals, add 2 mL 1*N* alc. NaOH to each flask in sequence, rinsing any sample adhering to neck or sides of flask into liq. in flask. Mix well by swirling. Stopper flasks and let stand 10 min. Do *not* have >9 flasks in a series. After 10 min, slowly dil. each to vol. with EtOAc, gently swirling flask during addn. (Voluminous ppt will form at this time.) Stopper flask and mix well. Complete this process for each flask before adding EtOAc to next. Let stand 10–20 min with occasional mixing.

Remix contents of flask and pour portion into centr. tube. Stopper tube and centr. 5 min. (Supernate should be clear; recentrif. if necessary.) Transfer 5 mL to 50 mL vol. flask, taking care not to transfer any pptd NaOAc which may remain on surface of soln after centrfg.

Add 35–40 mL cyclohexane to reagent blank followed by 2 mL Cu reagent and immediately dil. to vol. with cyclohexane. Stopper flask and mix. Use this soln to zero spectrophtr, using 1 cm cells at max.  $A$ , ca 420 nm. Proceed as above for sample. Det.  $A$  against reagent blank exactly 2 min after adding Cu reagent. Slight haze may appear on initial diln with cyclohexane. If it does not clear after adding Cu reagent, check for presence of excessive  $H_2O$  in analysis.

Water can be introduced by EtOAc, acetone,  $CH_3CN$ , alcohol, tetrahydrofuran, or contaminated glassware. Correct this condition before proceeding with analysis.

**6.369****Calculations****(a) Absorptivity of samples ( $a$ ).—****(1) Tech. malathion and emulsifiable concs**

$$a = (A \times 50 \times 50 \times 50) / (\text{mg sample} \times 5 \times 5)$$

$$= (A \times 5000) / \text{mg sample}$$

**(2) Wettable powders and dusts**

$$a = (A \times 100 \times 50 \times 50) / (\text{mg sample} \times 10 \times 5)$$

$$= (A \times 5000) / \text{mg sample}$$

**(b) Absorptivity of stds ( $a'$ ).—****(1) Malathion: Use formula in (a)(1).****(2) Potassium *O,O*-dimethyl phosphorodithioate**

$$a' = [(A \times 50 \times 50 \times 50) / (\text{mg sample} \times 5 \times 5)] \times 0.5939$$

$$= (A \times 2969) / \text{mg sample},$$

where 0.5939 is factor to convert K salt to equiv. wt malathion. (In general,  $a$  of stds are in range 17.2–17.6, corrected for quality of std, at concn 1 mg/mL in 1 cm cell.)

$$(3) \% \text{ Malathion} = (a \times \% \text{ purity of std}) / a'$$

**6.370****Preparation of Standard Curve (Optional)**

Transfer 3, 4, 5, and 6 mL aliquots centrfgd EtOAc soln of std, **6.368**, par. 3, into sep. 50 mL vol. flasks. Proceed with color development, and plot  $A$  against wt malathion in aliquot. Use std curve with considerable caution, since fade rate may vary from day to day, depending on solvs used for analysis. Std curve is not appropriate where fluctuations in temp. occur in laboratory environment.

**6.371****Interferences**

Test for free *O,O*-dimethyl phosphorodithioic acid or other interfering components in sample ext as follows: Transfer 2 drops ext to test tube, dil. with ca 10 mL cyclohexane, add 8 drops Cu reagent, and mix. Development of discernible yellow in soln indicates necessity of obtaining sample-blank correction.

Obtain sample-blank correction as follows: Transfer 5 or 10 mL aliquot sample to 50 mL vol. flask and dil. to vol. with EtOAc. (Do not add alc. NaOH soln.) For color development, transfer 5 mL diild sample soln and continue as in **6.368**. Correct  $A$  for base-treated sample and proceed with calcn.

**Gas Chromatographic Method (96)—Official First Action****6.372****Apparatus**

**(a) Gas chromatograph.**—With glass column, on-column injection system, flame ionization detector, and electrometer with sensitivity of  $\geq 10^{-11}$  amp driving 1 mv recorder. Drift should be  $< 1\%/hr$ . Totally solid state amplifier with FET input is recommended. Electronic digital integrator or computer calcd area measurements must be used. Integrator should have independent controls for selection of up and down slope sensitivities so that start and stop integration points can be selected. Automated sample injection system contributes significantly to precision. Hewlett-Packard Model 7600 is suitable when equipped as

described. Equiv. instrumentation may be used but may require modification of operating conditions to obtain good peak shape, adequate resolution, and appropriate retention times.

Typical conditions for Hewlett-Packard Model 7600 (instrument may have to be adjusted to give complete resolution of well shaped peaks): Cycle timers (min): analysis and stop integrate, 16; range,  $10^3$ ; temps ( $^\circ$ ): oven 180, injection port 200, flame detector 300; gas flow rotameters (mL/min): H 35, air 425, He carrier gas 30; integrator settings (adjusted so that deflections on slope meter do not exceed  $\pm 50\%$  before injection): noise suppression max., slope sensitivity up and down 0.1, BL reset delay 0.15, area threshold 1000; retention times (min): malathion 10, internal std 6, min. time between malathion and internal std 3.5.

**(b) Column.**—Borosilicate glass tube 1.22 m (6')  $\times$  4 mm id, 6 mm od, bent to fit chromatograph and packed with 5% SP-2401 or OV-210 on Gas-Chrom Q or Supelcoport (100/120 mesh). Can be purchased as prepd packing from Supelco, Inc., (specify "Pesticide Grade"); Alltech Associates, 202 Campus Dr, Arlington Heights, IL 60006; and Applied Science Laboratories, Inc. Use exclusively for malathion analysis.

**(c) Glass wool.**—Silane treated. (No. 14502, Applied Science Laboratories, Inc.)

**(d) Syringes.**—10  $\mu$ L, Series 700, Hamilton Co.

**(e) HI-EFF Fluidizer.**—Applied Science Laboratories, Inc.

**6.373****Reagents**

**(a) Internal std soln.**—1.2% *m*-Diphenoxybenzene in  $CHCl_3$ . Must not contain any impurities which elute at or near malathion peak. Bring soln to consistent temp. above ambient (e.g. 25 $^\circ$ ) before taking aliquots.

**(b) Malathion std solns.**—Accurately weigh ca 170, 200, and 230 mg malathion std (anal. grade, available from American Cyanamid Co.) into sep. preweighed 25 mL vol. flasks. Add by pipet 5 mL internal std soln and dil. to vol. with  $CHCl_3$ . Label A, B, and C. Soln B is working std soln for detn; solns A and C are used for linearity check and to guard against weighing error in prepn of working std soln. Solns are stable ca 4 weeks if kept tightly sealed in refrigerator. Warm to room temp. before use. Soln B can be prepd independently of solns A and C, if conditions of linearity check are met.

**6.374****Preparation and Conditioning of Column**

Weigh 6.25 g of trifluoropropylsilicone (SP-2401 or OV-210) in 250 mL beaker and dissolve in 125 mL EtOAc. Stir to obtain vortex and add 25 g solid support (Gas-Chrom Q or Supelcoport, 100/120 mesh) with continued agitation. Filter slurry thru Whatman No. 1 paper, or equiv., on buchner, using gentle vac. to minimize evapn of solv. Continue filtration until drop rate is ca 1/sec. Transfer packing to HI-EFF Fluidizer, connect source of N thru pressure reducer to base, and place fluidizer on controlled temp. hot plate set for 75 $^\circ$ . Continue gas flow until solv. vapors can no longer be detected by odor, taking care that packing is not blown out top of fluidizer.

To pack column, attach 75 mm funnel to exit end of prebent glass tube. Tap tube with pencil or small wooden rod, and add prepd packing in small amts until exit end is filled to ca 15 mm from end. Move funnel to entrance end of column. Insert pledget of silane-treated glass wool in exit end and attach source of moderate vac. to this end. Continue to add packing slowly with tapping until tube is filled to ca 20 mm from entrance end. Insert pledget of silane-treated glass wool in entrance end, compressing it only enough to hold it in place.

Condition column with He carrier gas flowing at 30 mL/min

≥15 hr (overnight) at 255° or ca 20° below max. temp. recommended for liq. phase. Exit end of column should not be connected to detector during this conditioning.

Connect exit end of column to detector, adjust controls to conditions given in 6.372(a), and let instrument come to equilibrium. Inject 3 μL aliquots std soln C until ≥3 consecutive injections give response ratios agreeing within 2%.

**6.375****Linearity Check**

Check gas chromatograph for linearity at least weekly, whenever new std solns are prepd, and whenever column, new or used, is newly installed in instrument.

Using digital integration for peak area measurements, det. appropriate attenuation setting and injection aliquot (2–4 μL) of std soln B to give area count of ≥100,000 counts (optimum electrometer output with acceptable noise level). Use conditions so detd for all samples and stds in series.

Inject triplicate aliquots of detd vol. of std solns A, B, and C into chromatograph, det. response ratio for each, and average ratios for each soln. Divide av. ratio for each soln by corresponding malathion content in mg. Ratio/mg should agree within 2%. Failure to meet this specification indicates either weighing error in prepn of a std soln or instrumental difficulties which must be corrected before proceeding with analysis of samples.

**6.376****Preparation of Sample**

(Analyze samples at least in duplicate)

(a) *Liquid formulations and technical materials.*—Accurately weigh sample contg ca 200 mg malathion into preweighed 25 mL vol. flask. Pipet in 5 mL internal std soln, dil. to vol. with CHCl<sub>3</sub>, and mix well.

(b) *Solid formulations containing 10% or more of malathion.*—Accurately weigh sample contg ca 1.0 g malathion and transfer to 200–250 mL (8 oz) bottle. Pipet in 50 mL CHCl<sub>3</sub>, stopper tightly, and shake on reciprocating shaker 30 min. Let settle ca 15 min; if not clear, centr. Layer of solids will float at interface. Avoid entrainment of particles by exerting pos. pressure from bulb on pipet while it is carefully inserted into soln for removal of aliquot. Particles in final soln can clog syringe needle. Transfer 10 mL aliquot clear soln to 25 mL vol. flask, pipet in 5 mL internal std soln, dil. to vol. with CHCl<sub>3</sub>, and mix well.

(c) *Solid formulations containing less than 10% malathion.*—Accurately weigh sample contg ca 400 mg malathion and transfer to 500 mL (16 oz) bottle. Add exactly 200 mL CHCl<sub>3</sub> and shake 30 min on reciprocal shaker. Let settle, observing precautions given in (b). Pipet 100 mL aliquot to 500 mL r-b flask and evap. to dryness. Pipet in 5 mL internal std soln and 20 mL CHCl<sub>3</sub>, swirl to dissolve residue, and mix well.

**6.377****Determination**

Inject duplicate aliquots of appropriate vol. of std soln B as detd in linearity check, 6.375. Response ratios should agree within 2%; if not, repeat with 2 more injections. Failure to meet specification with second pair of injections indicates instrumental difficulties which must be resolved before proceeding with analysis.

Inject duplicate aliquots of each sample soln of same vol. as std soln. Average response ratios for each sample. Precision considerations stated for std soln also apply to sample soln injection response.

Inject duplicate aliquots std soln B after every 2 sample solns. Average response ratios of stds immediately before and after sample solns. Use this av. to calc. malathion content of the 2 sample solns.

Each detn of av. response ratio for std soln B should yield value within 2% of previously detd value. Failure to meet this specification indicates instrumental drift which must either be corrected or compensated for by more frequent measurements of response of std soln B. In extreme cases, follow each sample injection with std injection but this would indicate an instability which should be corrected at once.

**6.378****Calculations**

For each sample injection, calc. response ratio:

$R = \text{area of malathion peak} / \text{area of internal std peak}$

$\% \text{ Malathion} = (R/R') \times (W'/W) \times P \times D$

where R' and R = av. response ratio for std soln B and sample soln, resp; W' and W = g malathion std and sample, resp.; P = % purity of malathion std; and D = diln factor (1 for liqs; (50/10)(25/25) = 5 for solids ≥10% malathion; and (200/100)(25/25) = 2 for solids <10% malathion).

**Parathion****Gas Chromatographic Method (97)—Official First Action**

(Not applicable to dusts and powders)

**6.379****Standard Solutions**

(a) *Dipentyl phthalate internal std soln.*—Dissolve 2.0±0.1 g dipentyl phthalate (Eastman Kodak Co., No. P2473, or equiv.) in CS<sub>2</sub> and dil. to 500 mL with CS<sub>2</sub>.

(b) *Parathion std soln.*—Accurately weigh ca 125 mg parathion (Monsanto Chemical Co., or equiv.) into 50 mL g-s erlenmeyer, pipet in 25 mL internal std soln, and mix thoroly.

**6.380****Preparation of Sample**

Accurately weigh sample contg ca 125 mg parathion into 50 mL g-s erlenmeyer. Pipet in 25 mL internal std soln and mix thoroly.

**6.381****Gas Chromatograph**

See 6.402. Column should have ≥1200 theoretical plates for parathion. Vary attenuation and injection vol. (1–2 μL) so that peak hts of parathion and dipentyl phthalate are 60–80% full scale on 1 mv recorder. Retention times for parathion and dipentyl phthalate are 6–8 and 8–10.5 min, resp.

**6.382****Determination**

Proceed as in 6.403, except substitute parathion for Me parathion and dipentyl phthalate for p,p'-DDE.

**6.383****Calculations**

Proceed as in 6.404, except substitute parathion for Me parathion and delete F from equation.

**High Pressure Liquid Chromatographic Method (97)  
Official First Action**

(Not applicable to dusts and powders)

**6.384****Apparatus**

(a) *Liquid chromatograph.*—See 6.405(a), except use eluant flow rate of 1.5 mL/min (ca 800 psi).

(b) *Liquid chromatographic column.*—See 6.294(b).

## 6.385

## Reagents

- (a) *Choroform*.—See 6.406(a).  
 (b) *Eluant*.—Stir 500 mL  $\text{CHCl}_3$  on mag. stirrer 3–4 min under moderate vac. (ca 350 mm Hg).  
 (c) *Internal std soln*.—Accurately weigh ca 110 mg benzophenone (MC/B Manufacturing Chemists, No. BX0410, or equiv.) into 250 mL vol. flask, and dissolve and dil. to vol. with  $\text{CHCl}_3$ .  
 (d) *Parathion std solns*.—(1) *Stock soln*.—1500  $\mu\text{g/mL}$ . Accurately weigh ca 75 mg anal. grade parathion (Monsanto Chemical Co., or equiv.) into 50 mL vol. flask, and dissolve and dil. to vol. with  $\text{CHCl}_3$ . (2) *Working soln*.—(150  $\mu\text{g}$  parathion + 44  $\mu\text{g}$  benzophenone)/mL. Pipet 5 mL stock soln and 5 mL internal std soln into 50 mL vol. flask, and dil. to vol. with  $\text{CHCl}_3$ .

## 6.386

## Preparation of Sample

Accurately weigh sample contg ca 75 mg parathion into 50 mL vol. flask, and dissolve and dil. to vol. with  $\text{CHCl}_3$ . Pipet 5 mL sample soln and 5 mL internal std soln into 50 mL vol. flask, and dil. to vol. with  $\text{CHCl}_3$ .

## 6.387

## Determination

Proceed as in 6.408, except substitute parathion for Me parathion and benzophenone for acetophenone, and delete *F* from equation. Retention times for parathion and benzophenone are 4.0–5.5 and 7–9 min, resp.

## Volumetric Method (98)—Official First Action

(Applicable to dusts and powders only. *Caution*: See 51.041.)

## 6.388

## Apparatus

- (a) *Photoelectric colorimeter*.—With filter to give max. *T* between 400 and 450 nm. Spectrophtr set at 405 nm may also be used.  
 (b) *Potentiometer*.—With adapter for outside Pt and calomel electrodes. Dead-stop end point equipment may also be used.

## 6.389

## Reagents

- (a) *Zinc dust*.—Low in Fe.  
 (b) *Sulfanilic acid*.—Anhyd. recrystd material. Check purity by N detn.  
 (c) *p-Nitrophenol*.—Mp 112–113°.  
 (d) *Sodium nitrite std soln*.—0.1*N*. Stdze weekly. Accurately weigh 0.4–0.45 g of the sulfanilic acid into 400 mL tall beaker. Add 80 mL  $\text{H}_2\text{O}$ , 10 mL HCl, 30 mL HOAc, and 5 g NaBr. Place electrodes and mech. stirrer in reaction mixt. and titr. with the 0.1*N*  $\text{NaNO}_2$ . Add in 5 mL portions until within 1 mL of calcd end point; then add  $\text{NaNO}_2$  soln in 0.1 mL portions until max. rise in potential is obtained. At first, 3–5 min is required for potential to become const; as end point approaches, especially after 0.1 mL addns, reaction should be complete within 1 min. As alternative, dead-stop end point technic may be used (98), or following spot test, adding  $\text{NaNO}_2$  soln in 4 drop portions near end point: Dip glass rod into soln being titrd and touch rod quickly to piece of KI-starch paper, (e). End point is reached when intense blue-black color appears immediately and can be obtained repeatedly during 1 min period without further addn of  $\text{NaNO}_2$ .

Normality  $\text{NaNO}_2$  soln = g sulfanilic acid  $\times$  1000/(mL  $\text{NaNO}_2 \times 173.2$ ).

- (e) *Starch iodide paper*.—Triturate 10 parts starch with 200 parts  $\text{H}_2\text{O}$ , bring to bp, and add 1 part KI. Impregnate strips of filter paper with this soln, dry, and preserve in g-s bottles.

## 6.390

## Preparation of Standard Curve of p-Nitrophenol

Accurately weigh 100 mg *p*-nitrophenol, transfer to 1 L vol. flask, and dil. to vol. with 0.1*N* NaOH. Transfer 2, 4, 6, 8, 10, and 20 mL aliquots of this soln to 100 mL vol. flasks and dil. each soln to vol. with 0.1*N* NaOH. Read *A* of each soln in photoelec. colorimeter (400–450 nm) or spectrophtr (405 nm) against  $\text{H}_2\text{O}$  as ref. Plot *A* against concn in mg/mL.

## 6.391

## Preparation of Sample

*Dust preparations and wettable powders*.—Transfer weighed sample to thimble and ext with 150 mL ether in Soxhlet app. 1 hr. Transfer ether ext to 250 mL separator, and sep. *p*-nitrophenol and parathion as in 6.392. Det. sample size by parathion concn as follows: 10%, 6.75 g; 15% 4–5 g; 25%, 2.5–3.5 g.

## 6.392

## Separation of Parathion and p-Nitrophenol

Ext ether soln with four (or until ext is colorless) 20 mL portions chilled 1%  $\text{Na}_2\text{CO}_3$  soln, collecting combined aq. layers in 200 mL vol. flask. Transfer ether layer to 400 mL tall beaker, rinsing separator with small portions ether.

## 6.393

## Determination of p-Nitrophenol

Add 20 mL 1*N* NaOH to combined aq. exts and dil. to vol. with  $\text{H}_2\text{O}$ . Measure *A* of soln as in 6.390 and read concn *p*-nitrophenol in mg/mL from std curve.

% *p*-Nitrophenol = (mg/mL)  $\times$  200  $\times$  100/(1000  $\times$  g sample).

## 6.394

## Determination of Parathion

(*Caution*: See 51.011, 51.039, and 51.054.)

Add 35 mL HOAc-HCl mixt. (9+1) to ether soln, 6.392. Add 2 g Zn dust, cover beaker with watch glass, and gently heat soln on steam bath 45 min, or until most of ether evaps and soln is colorless. Add 30 mL HCl and heat 10 min longer to complete soln of Zn dust. Wash down beaker and watch glass with  $\text{H}_2\text{O}$ . Filter reduced mixt. thru paper and rinse beaker thoroly with  $\text{H}_2\text{O}$ . Dil. to 125 mL and cool to room temp. Add 5 g NaBr (or KBr) and titr. with 0.1*N*  $\text{NaNO}_2$  as in 6.389(d).

% Parathion = mL  $\text{NaNO}_2 \times$  normality  $\times$  29.13/g sample.

## Colorimetric Method (99)—Official First Action

(Applicable to dusts and powders only)

## 6.395

## Principle

Parathion is extd with alcohol and hydrolyzed with KOH to form *K p*-nitrophenate, which is detd colorimetrically.

## 6.396

## Preparation of Standard Curve

Weigh 60 mg reagent grade *p*-nitrophenol into 100 mL vol. flask, dissolve in alcohol, and dil. to vol. with alcohol. Pipet 10 mL into 100 mL vol. flask and dil. to vol. with alcohol. Prep. *p*-nitrophenol stds contg 0.3, 0.18, and 0.06 mg/100 mL by pipetting 5, 3, and 1 mL aliquots, resp., of second diln into sep. 100 mL vol. flasks, adding from pipet 5 mL 1*N* KOH in 50% alcohol, and dilg to vol. with 50% alcohol. Measure *A* at 405 nm in 1 cm Corex cells against 50% alcohol and plot *A* against concn.

## 6.397

## Preparation of Sample

Weigh sample contg ca 10 mg parathion into 250 mL g-s flask. Pipet in 100 mL alcohol and shake occasionally during 10 min. Filter ca 25 mL into g-s container.

**6.398 Determination of Free *p*-Nitrophenol**

Pipet 10 mL aliquot of above soln into 100 mL vol. flask and dil. to vol. with 50% alcohol. Add 5 drops 1*N* KOH in 50% alcohol, and measure *A* at 405 nm within 2 min against 50% alcohol. Calc. free *p*-nitrophenol.

**6.399 Determination of Parathion**

Pipet 5 mL filtered soln into 125 mL g-s flask, pipet in 5 mL 1*N* KOH in 50% alcohol, and add glass beads to prevent bumping. Reflux  $\geq 30$  min. Cool, and transfer to 100 mL vol. flask with 50% alcohol. Dil. to vol. with 50% alcohol and measure *A* as in 6.396. Calc. parathion, using std curve, dilns, and factor: Parathion = *p*-nitrophenol/0.478. Correct for free *p*-nitrophenol.

**Methyl Parathion****Gas Chromatographic Method (100)—Official First Action****6.400 Standard Solutions**

(a) *p,p'*-DDE internal std soln.—Dissolve  $5.0 \pm 0.1$  g 2,2-bis(*p*-chlorophenyl)-1,1-dichloroethylene (*p,p'*-DDE, No. 12.389-7, Aldrich Chemical Co., Inc., or equiv.) in  $\text{CS}_2$  and dil. to 1 L with  $\text{CS}_2$ .

(b) *Methyl parathion std soln.*—Accurately weigh ca 125 mg Me parathion (Monsanto Chemical Co., 800 N Lindbergh Blvd, St. Louis, MO 63166, or equiv.) into 50 mL g-s erlenmeyer, pipet in 25 mL internal std soln, and mix thoroly.

**6.401 Preparation of Sample**

(a) *Liquid.*—Accurately weigh into 50 mL g-s erlenmeyer sample contg ca 125 mg Me parathion. Pipet in 25 mL internal std soln and mix thoroly.

(b) *Wettable powder.*—Accurately weigh into 100–150 mL (4 oz) round bottle sample contg ca 625 mg Me parathion. Pipet in 50 mL  $\text{CHCl}_3$ -acetone (9+1), cap, and shake mech. 30 min. Let settle and pipet 10 mL supernate into 50 mL g-s erlenmeyer. Place erlenmeyer in 55°  $\text{H}_2\text{O}$  bath and evap. solv. under stream of dry air or N. Pipet in 25 mL internal std soln and mix thoroly.

**6.402 Gas Chromatograph**

Use instrument equipped with flame ionization detector and 1.2 mm  $\times$  4 (id) mm glass column packed with 1.5% SE-30 plus 1.5% OV-210 on 80–100 mesh Gas-Chrom Q.

Prep. column by accurately weighing ca 0.12 g SE-30 and ca 0.12 g OV-210 into 250 mL beaker. Add 50 mL  $\text{CHCl}_3$ -acetone (3+2), cover with watch glass, and heat on steam bath until stationary phases are dissolved. Speed dissoln of SE-30 by spreading material on walls of beaker with small spatula or stirring rod. Add enough 80–100 mesh Gas-Chrom Q to yield 1.5% of each phase on solid support. Heat on steam bath, stirring frequently until all solv. is removed. Air dry 2–3 hr. Pack in column and condition 24 hr at 245° with N or He at 30 mL/min. Column should have  $\geq 1200$  theoretical plates for *p,p'*-DDE.

Typical operating conditions: temps (°)—inlet 210, column  $180 \pm 10$ , detector 250; N or He carrier gas, 55–75 mL/min; air and H as specified by manufacturer; attenuation and injection vol. (1–2  $\mu\text{L}$ ) varied so that peak hts of Me parathion and *p,p'*-DDE are 60–80% full scale on 1 mv recorder. Retention times for Me parathion and *p,p'*-DDE are 3.5–5.5 and 6–8 min, resp.

**6.403 Determination**

Inject aliquots of std soln until peak ht ratio of Me parathion : *p,p'*-DDE varies  $\leq 1\%$  for successive injections. Then make duplicate injections of sample followed by duplicate injections of std. Peak ht ratios of stds must be within  $\pm 1\%$  of first accepted

std values or repeat series of injections. Repeat for addnl samples.

**6.404 Calculations**

Calc. peak ht ratios for both duplicate std injections preceding and following samples. Average the 4 values (*R'*). Calc. and average peak ht ratios of the 2 samples (*R*).

$$\% \text{ Me parathion} = (R/R') \times (W'/W) \times F \times P,$$

where *W* and *W'* = mg sample and std, resp., *F* = 1 for liq. and 5 for wettable powder samples; and *P* = % purity of std.

**High Pressure Liquid Chromatographic Method (101)  
Official First Action****6.405 Apparatus**

(a) *Liquid chromatograph.*—Waters Model ALC 202/GPC 204 (Waters Associates, Inc.), or equiv., with 254 nm UV detector and 10 mv recorder. Typical operating conditions: eluant flow rate, 1.2 mL/min (ca 700 psi); detector sensitivity, 0.16 A unit full scale; temp., ambient; valve injection vol., 10  $\mu\text{L}$ .

(b) *Liquid chromatographic column.*—See 6.294(b).

(c) *Chromatographic tubes.*—Glass, 900  $\times$  25 (id) mm, with coarse porosity frit in bottom (SGA Scientific, Inc., No. JC-2650, or equiv.).

**6.406 Reagents**

(a) *Chloroform.*—Alcohol-free with  $<0.01\%$   $\text{H}_2\text{O}$  (Burdick & Jackson Laboratories, Inc., distd in glass, or equiv.).

(b) *Silicic acid-water.*—75% (w/v). Add 25 mL  $\text{H}_2\text{O}$  to 75 g silicic acid (Mallinckrodt Chemical Works, Code 2847, or equiv.), and shake until lumps disappear.

(c) *Water-saturated chloroform.*—Shake 700 mL  $\text{CHCl}_3$  with 150 mL  $\text{H}_2\text{O}$  2–3 min, and pass thru 900  $\times$  25 mm glass tube packed with 100 g silicic acid- $\text{H}_2\text{O}$ .

(d) *Eluant.*—Blend 200 mL  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$  with 300 mL  $\text{CHCl}_3$  on mag. stirrer 2–3 min under moderate vac. (ca 350 mm Hg).

(e) *Internal std soln.*—Accurately weigh ca 115 mg acetophenone (MC/B Manufacturing Chemists, No. AX0164, or equiv.) into 250 mL vol. flask, and dissolve and dil. to vol. with  $\text{CHCl}_3$ .

(f) *Methyl parathion std solns.*—(1) *Stock soln.*—700  $\mu\text{g}/\text{mL}$ . Accurately weigh ca 70 mg anal. grade Me parathion (Monsanto Chemical Co., or equiv.) into 100 mL vol. flask, and dissolve and dil. to vol. with  $\text{CHCl}_3$ . (2) *Working soln.*—(70  $\mu\text{g}$  Me parathion + 46  $\mu\text{g}$  acetophenone)/mL. Pipet 5 mL stock soln and 5 mL internal std soln into 50 mL vol. flask, and dil. to vol. with  $\text{CHCl}_3$ .

**6.407 Preparation of Sample**

Accurately weigh ca 95 mg tech. Me parathion into 100 mL vol. flask, or accurately weigh emulsifiable sample contg ca 35 mg Me parathion into 50 mL vol. flask, and dil. to vol. with  $\text{CHCl}_3$ . Pipet 5 mL sample soln and 5 mL internal std soln into 50 mL vol. flask, and dil. to vol. with  $\text{CHCl}_3$ .

**6.408 Determination**

Pump sufficient eluant thru column to equilibrate system. Inject 10  $\mu\text{L}$  working std soln onto column thru sampling valve, and adjust operating conditions to give peak hts 60–80% full scale and retention times of 3.5–5.0 and 5.5–8.0 min for Me parathion and acetophenone, resp. Repeat injections until ratio of Me parathion to acetophenone peak hts is within  $\pm 1\%$  of previous injection. Without changing conditions, alternately inject 10  $\mu\text{L}$  aliquots of working std soln and duplicate 10  $\mu\text{L}$  aliquots of sample soln until peak ht ratios for sample soln vary

≤1% for successive injections. Average last 2 peak ht ratios for sample and for std, resp., and calc. % Me parathion.

$$\% \text{ Me parathion} = (R/R') \times (W'/W) \times (P/F),$$

where  $R$  and  $R'$  = av. peak ht ratios of Me parathion to acetophenone for sample and std, resp.;  $W$  and  $W'$  = mg sample and std, resp.;  $P$  = % purity of std; and  $F$  = 1 for tech. and 2 for emulsifiable samples.

#### Methyl Parathion in Water-based Microencapsulated Formulations

##### Gas Chromatographic Method (102)—Official First Action

###### 6.409

###### Principle

Me parathion is released from microcapsules by grinding, and is extd into  $\text{CH}_3\text{CN}$ . Dimethoate is added as internal std and concn of Me parathion is detd by flame ionization GLC.

###### 6.410

###### Apparatus

(a) *Gas chromatograph*.—Perkin-Elmer Model 900, or equiv., with flame ionization detector, glass lined injection port, 1 mv strip chart recorder, and 1.8 m × 2 (id) mm glass column packed with 3% OV-17 on 80–100 mesh Supelcoport (Supelco, Inc.). Typical operating conditions: temps (°): column 200, injection port 225, detector 250; flow rates (mL/min): He carrier gas 35, air 400, H optimize for max. sensitivity; sample: 1  $\mu\text{L}$   $\text{CH}_3\text{CN}$  contg dimethoate and Me parathion with retention times of ca 3 min and 4 min, resp. Injection vol. may be varied to give peak hts 50–90% of full scale.

(b) *Sample grinder*.—Spex Industries Mixer/Mill No. 8000 (Spex Industries, Inc., PO Box 798, Metuchen, NJ 08840) or 40 mL Corning 7726 glass tissue grinder (No. 441969, Corning Glass Works).

(c) *Weighing dishes*.—With natural Al surface to which sample does not stick (Fisher Scientific Co., No. 8-732, or equiv.).

###### 6.411

###### Reagents

(a) *Dimethoate*.—Cygon® insecticide, anal. grade (obtainable from American Cyanamid Co.).

(b) *Methyl parathion*.—Anal. grade (obtainable from Monsanto Chemical Co.).

###### 6.412

###### Determination of Correction Factor

Prep. 2 duplicate std solns by accurately weighing ca 0.1 g Me parathion and ca 0.1 g dimethoate directly into same 50 mL vol. flask, and dilg to vol. with  $\text{CH}_3\text{CN}$ . Shake thoroly to dissolve. Inject ca 1  $\mu\text{L}$  each soln into gas chromatograph. Repeat injections until ratio of peak hts is reproducible; then record peak hts and attenuations for dimethoate and Me parathion.

$$CF = (P_d \times W_{mp}) / (P_{mp} \times W_d),$$

where  $CF$  = correction factor,  $P_d$  = peak ht × attenuation for dimethoate,  $W_{mp}$  = g Me parathion,  $P_{mp}$  = peak ht × attenuation for Me parathion, and  $W_d$  = g dimethoate.

Average results for the 2 solns.

###### 6.413

###### Preparation of Sample

Prep. duplicate samples as follows: Thoroly shake sample container to assure that slurry of microcapsules is homogeneous. Withdraw ca 1 g sample using medicine dropper while stirring. Immediately discharge contents into tared Al weighing dish, and record exact wt. Transfer to Mixer/Mill or glass tissue grinder, using small amt of  $\text{CH}_3\text{CN}$ . (If anal. balance can accommodate grinder, sample may be weighed directly in it.) Add ca 30 mL  $\text{CH}_3\text{CN}$  and grind ca 4 min. Quant. transfer ground sample

to 100 mL vol. flask, using  $\text{CH}_3\text{CN}$ . Accurately weigh ca 0.2 g dimethoate in tared Al weighing dish, transfer quant. to vol. flask, and dil. to vol. with  $\text{CH}_3\text{CN}$ .

###### 6.414

###### Determination

Inject ca 1  $\mu\text{L}$  soln contg sample and internal std into gas chromatograph. Record peak hts and attenuations for dimethoate and Me parathion.

$$\text{wt } \% \text{ Me parathion} = (P_{mp} \times W_d \times CF \times 100) / (P_d \times W),$$

where  $P_{mp}$  = peak ht × attenuation for Me parathion,  $W_d$  = g dimethoate,  $CF$  = correction factor,  $P_d$  = peak ht × attenuation for dimethoate, and  $W$  = g sample.

Analyze duplicate samples and av. results.

#### Phorate (Thimet®) (O,O-Diethyl S-(Ethylthio)methyl Phosphorodithioate) (703)—Official Final Action

(Applicable to analysis of 5 and 10% granules. Presence of other pesticides and extractable org. materials such as dispersing agents, emulsifiers, and solvs requires testing for interference.)

###### 6.415

###### Apparatus

(a) *Infrared spectrophotometer*.—Capable of measurement in 7.9–8.6  $\mu\text{m}$  range; with 0.5 mm cell.

(b) *Chromatographic tube*.—15 × 450 mm with stopcock or Ultramax valve (Fischer & Porter Co., Lab Crest Scientific Div., Cat. No. 274–019 or 274–100).

###### 6.416

###### Reagents

(a) *Phorate reference std*.—Purified (obtainable from American Cyanamid Co.).

(b) *Phorate std soln*.—Accurately weigh by difference from Smith or Lunge pipet 1.0–1.1 g Phorate Ref. Std into 250 mL beaker contg 45 mL  $\text{CH}_3\text{CN}$ .

(c) *Cyclohexane*.—Practical grade.

(d) *Acetonitrile*.—Practical grade, bp 82–84°.

###### 6.417

###### Preparation of Sample Solution

(Caution: See 51.011, 51.040, and 51.043.)

Accurately weigh  $20 \pm 0.01$  g sample of 5% granular material ( $10 \pm 0.01$  g for 10%). Place small glass wool plug in bottom of chromatgc tube, transfer sample to tube, and gently tap sides with spatula or rod to settle contents. Place 250 mL beaker under column. Add 50 mL  $\text{CH}_3\text{CN}$  to column and let percolate thru at rate of 40–50 drops/min until flow stops. Place beakers contg std (from 6.416(b)) and sample solns in shallow  $\text{H}_2\text{O}$  bath at 30–35° and evap. under gentle stream of air until odor of  $\text{CH}_3\text{CN}$  is no longer detectable. (Sample solns on evapn will change from clear to cloudy and then to residue of 2 layers.) Treat residue with four 5 mL portions and one 4 mL portion cyclohexane, quant. transferring cyclohexane layers to 25 mL vol. flask. (Keep cyclohexane-immiscible layer in beaker during each extrn.) Dil. to vol. with cyclohexane.

###### 6.418

###### Determination

Using hypodermic syringe, fill 0.5 mm cell with prepd std soln, and obtain IR spectrum from 7.9 to 8.6  $\mu\text{m}$ . (With single beam instrument, adjust to give 75%  $T$  at 8.2  $\mu\text{m}$  with cell contg std soln in position.) Using same instrument settings, treat prepd sample solns similarly.

Draw baseline from inflection points 8.10 to 8.48  $\mu\text{m}$ . Draw perpendicular from 0 radiation line thru absorption peak, and measure distance from 0 to baseline ( $Y$ ) and from 0 to absorption

peak (X) in same units. Calc.  $A = \log (Y/X)$  for sample (A) and std (A').

% Phorate =  $(A/A') \times (\text{wt std/wt sample}) \times \% \text{ purity of std.}$

#### 6.419 ★ Sulfoxide (n-Octyl Sulfoxide of Isosafrole) (104)—Official First Action

Sulfoxide is sepd from solvs, emulsifiers, pyrethrins, and other insecticides by silicic acid column chromatgy with successive eluting solns:  $\text{CHCl}_3$ , 2% acetone in  $\text{CHCl}_3$ , and 10% acetone in  $\text{CHCl}_3$ . Sulfoxide is removed in last eluate and is detd by UV spectrophotometry. See 6.296–6.302, 11th ed.

#### Tetraethylpyrophosphate (TEPP) (105)—Official Final Action

(Caution: See 51.041.)

#### 6.420

#### Reagents

- (a) *Indicator*.—0.1% aq. soln Me red or chlorophenol red.  
 (b) *Amberlite IR-4B(OH) (free base form) resin*.—Anal. grade. Amberlite IR-45, Dowex 3, or equiv., are satisfactory.

#### 6.421

#### Preparation of Resin Column

Screen resin to remove particles <30 mesh. Slurry 30 g screened resin with  $\text{H}_2\text{O}$ , and pour into 100 mL buret contg small plug of glass wool at bottom. Wash resin column with 150 mL 3% NaOH soln at flow rate of ca 5 mL/min and then rinse with  $\text{H}_2\text{O}$  until effluent is acid to phthln, adjusting stopcock of buret so flow rate is ca 25 mL/min. Wash with aq. acetone (1+3) to displace  $\text{H}_2\text{O}$ . Column is now ready for use.

*Notes:* Because channeling may result if column runs dry, keep liq. level ca 2.5 cm above resin bed at all times. Because resin tends to pack in column as it adsorbs acidic material, expand resin bed after each detn before adding new sample by back-washing with acetone (1+3) as follows: Connect large funnel to tip of buret with rubber hose, and add the dil. acetone from funnel until liq. level reaches top of buret; let resin settle, and then let soln flow from buret until surface is 2.5 cm above resin bed. Column is now ready to receive next sample.

After 8–10 samples have passed thru column, regenerate resin by repeating original treatment with 3% NaOH soln,  $\text{H}_2\text{O}$ , and acetone (1+3). Washing with dil. acetone must be continued until effluent is colorless.

#### 6.422

#### Determination

(a) *In purified or technical grades of tetraethylpyrophosphate not mixed with solvent, emulsifying agent, etc.*—From 5–10 mL weighing buret, weigh by difference, to nearest mg, 2.5 g sample (1.0 g if tetraethylpyrophosphate content is >50%) into 50 mL acetone (1+3) in 125 mL separator. Mix by swirling, and let soln stand 15 min at  $25 \pm 2^\circ$ . Let soln flow thru resin column by gravity at ca 25 mL/min, and catch effluent in 250 mL vol. flask. Wash separator and column with three 50 mL portions acetone (1+3), collecting washings in same flask. Dil. combined effluent to vol. with  $\text{H}_2\text{O}$ , mix, and transfer 100 mL aliquot to 250 mL beaker. Add 50 mL 0.1N NaOH to beaker, stir well, let stand 30 min at room temp., and back-titr. with 0.1N HCl, using pH meter (or indicator, 6.420(a), if pH meter is not available). Calc. % tetraethylpyrophosphate =  $\text{net mL } 0.1N \text{ NaOH} \times 3.67/\text{wt sample taken}$ .

(b) *In formulations of tetraethylpyrophosphate containing organic solvent and emulsifying agent*.—Proceed as in (a), except filter acetone soln thru 25 mm cotton plug in cylindrical

funnel (25 mm diam., 75 mm long) before adding it to column if oil seps from soln. Pass acetone washings successively thru separator, cylindrical funnel, and resin column as in (a). (Cotton plug absorbs oil.)

#### Organic Thiocyanates

#### Thiocyanate Nitrogen in Livestock or Fly Sprays (106)—Official Final Action

(Caution: See 51.041.)

#### 6.423

#### Reagents

- (a) *Strong potassium polysulfide soln*.—Dissolve 180 g KOH in 120 mL  $\text{H}_2\text{O}$ . Sat. 100 mL of this soln with  $\text{H}_2\text{S}$  (ca 42 g) (Caution: See 51.059) while cooling. Add remaining 100 mL KOH soln and 80 g S. Shake until dissolved.  
 (b) *Mixed sulfide soln*.—To 100 mL (a) add 50 g  $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$ , 30 g KOH, and 200 mL  $\text{H}_2\text{O}$ .  
 (c) *Sodium bisulfite*.— $\text{Na}_2\text{S}_2\text{O}_5$  or  $\text{NaHSO}_3$ .  
 (d) *Copper sulfate soln*.—20% aq. soln  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ .  
 (e) *Wash soln*.—To 300 mL  $\text{H}_2\text{O}$  add 1 mL  $\text{H}_2\text{SO}_4$  (1+4), 1 g (c), 10 mL (d), and 12 g  $\text{Na}_2\text{SO}_4$ , and pass  $\text{SO}_2$  into soln 10 min.

#### 6.424

#### Preparation of Sample

Weigh sample preferably contg ca 0.03 g thiocyanate N into 250 mL g-s erlenmeyer. (If SCN content is very low, do not unduly increase amt sample without correspondingly increasing amt mixed sulfide soln used; 20–25 g fly spray is usually enough.) Add 35 mL mixed sulfide soln and shake vigorously at room temp. 10 min, during which time reaction is nearly completed. Heat to  $70^\circ$  on steam bath, carefully releasing pressure resulting from heating, shake 15 min at  $70^\circ$ , and cool.

*Removal of petroleum oil*.—Transfer mixt. to separator with ca 200 mL  $\text{H}_2\text{O}$ . Add 50 mL pet ether, shake, and drain aq. layer into 600 mL beaker. Wash pet ether layer with two 10 mL portions  $\text{H}_2\text{O}$ , adding washings to main soln. (If emulsions form during washing, break by acidifying with  $\text{H}_2\text{SO}_4$  (1+4).) Drain aq. layer and wash pet ether layer with  $\text{H}_2\text{O}$  as above. Discard pet ether layer.

#### 6.425

#### Determination

Dil. combined aq. soln to ca 300 mL and neutze with  $\text{H}_2\text{SO}_4$  (1+4), using litmus paper as outside indicator. Add 2 mL  $\text{H}_2\text{SO}_4$  (1+4), quickly bring mixt. to bp, and boil 8 min to remove  $\text{H}_2\text{S}$ . Cool. If fatty acids or oils are present, transfer to separator, ext with pet ether, and return aq. phase to original beaker. Filter thru small buchner and transfer filtrate to beaker. Neutze to litmus paper with 10% KOH soln and add 1 mL  $\text{H}_2\text{SO}_4$  (1+4). Add 1 g Na bisulfite and stir until dissolved. Add excess (ca 15 mL)  $\text{CuSO}_4$  soln and pass  $\text{SO}_2$  into soln 10 min.

Let pptd  $\text{CuSCN}$  settle 2 hr, and filter with suction thru 56 mm buchner coated with layer of asbestos (Caution: See 51.086), upon which is placed No. 42 Whatman paper, or equiv., second layer of asbestos, layer of diatomite, and finally third layer of asbestos. If filtrate is not clear, centr. soln at 2000 rpm 10–15 min, and pour thru filter again. Wash filter and ppt once or twice with wash soln, continue suction until filter pad is dry, and transfer to 800 mL Kjeldahl flask. (Filter pad may be folded in filter paper together with bits of moist filter paper used to wipe out buchner, and whole placed in Kjeldahl flask.) Add few glass beads, 35 mL  $\text{H}_2\text{SO}_4$ , 10 g  $\text{K}_2\text{SO}_4$ , and ca 0.7 g  $\text{HgO}$  or 0.65 g  $\text{Hg}$ . (Caution: See 51.030 and 51.065.) Digest until colorless; then 15 min more. Det. N as in 2.057, second par. Perform blank analysis on paper, filter pad, and reagents.

★ Surplus method—see inside front cover.

**Thiocarbamate Herbicides (107)—Official First Action**

(S-Ethyl Dipropylthiocarbamate (EPTC, Eptam®), S-Ethyl Hexahydro-1H-azepine-1-carbothioate (Molinate, Ordram®), S-Ethyl Cyclohexylethylthiocarbamate (Cycloate, Ro-Neet®), S-Ethyl Diisobutylthiocarbamate (Butylate, Sutan®), S-Propyl Butylethylthiocarbamate (Pebulate, Tillam®), S-Propyl Dipropylthiocarbamate (Vernolate, Vernam®))

**Gas Chromatographic Method**

(Applicable to liq. and granular formulations.

Caution: See 51.041.)

**6.426****Apparatus**

(a) *Gas chromatograph*.—With flame ionization detector. Operating conditions: temps (°)—injection port 225, column 130 (EPTC and butylate), 170 (molinate), 140 (cycloate, vernolate), 150 (pebulate), detector 250; gas flows (mL/min)—N carrier 30–35, H<sub>2</sub> 25–30, air 200–300 (or as specified by manufacturer).

(b) *Recorder*.—1 mv full scale sensitivity and 1 sec response.

(c) *Columns*.—6' (1.8 m) × 0.25" od, Pyrex, Al, or stainless steel, packed with 3% OV-17 on 60–80 Gas-Chrom Q, or equiv. (for molinate), and 3% SE-30 or OV-1 on 60–80 mesh Gas-Chrom Q, or equiv. (for other 5 compds). Condition columns 12 hr at 250° under N flow of 30 mL/min.

**6.427****Preparation of Standards**

(a) *Internal std solns*.—Accurately weigh ca 400 mg each ref. grade thiocarbamate (EPTC, cycloate, butylate, or pebulate; Stauffer Chemical Co., 1200 S 47th St, Richmond, CA 94804) and transfer to sep. 100 mL vol. flasks. Dil. to vol. with CS<sub>2</sub>-CHCl<sub>3</sub>-MeOH (80+15+5), and mix thoroly.

(b) *Std solns*.—Accurately weigh ca 100 mg each ref. grade thiocarbamate into sep. 2 oz (50 mL) polyethylene-lined screw-cap, conical bottles. Add 25 mL internal std soln indicated below, and mix thoroly.

Std soln	Approx. retention time, min	Internal std soln added	Approx. retention time, min
EPTC	2.0	Butylate	2.4
Molinate	4.3	Cycloate	4.8
Cycloate	5.4	Pebulate	2.6
Butylate	2.4	EPTC	2.0
Pebulate	4.0	Cycloate	8.0
Vernolate	3.5	Cycloate	5.5

**6.428****Preparation of Sample**

Accurately weigh sample contg ca 100 mg thiocarbamate into 2 oz (50 mL) polyethylene-lined screw-cap, conical bottle. Add 25 mL appropriate internal std soln, (a), as indicated in (b), and shake thoroly. Vigorously shake granular formulations 30 min on wrist-action shaker.

**6.429****Determination**

Inject 2 µL clear supernate or soln into chromatograph preadjusted to appropriate conditions. Make triplicate injections of sample and appropriate std soln in random order. Det. peak areas, preferably with digital integrator.

Adjust sensitivity of gas chromatograph so that larger component or internal std peak is ca ¾ full scale.

**6.430****Calculations**

Response Factor (RF) = ( $I' \times \text{g compd in std soln} \times \% \text{ purity}$ )/ $S'$

Wt % compd = ( $RF \times S$ )/ $I \times \text{g sample}$ ,

where  $I$  and  $I'$  = areas of internal std peak in sample and std solns, resp.; and  $S$  and  $S'$  = areas of compd peak in sample and std solns, resp.

**Triazines and Other Pesticides (108)—Official Final Action**

(See Table 6:03 for applicability to and official status of specific compds.)

**AOAC-CIPAC Method****6.431****Standard Solutions**

(Caution: See 51.041.)

(a) *Dieldrin internal std soln*.—Std should be ≥90% pure and contain no impurities eluting at retention time for pesticide being detd. (1) *For propazine*.—Weigh 14.0±0.1 g tech. dieldrin, dissolve in ca 300 mL CHCl<sub>3</sub>, and dil. to 1 L with CHCl<sub>3</sub>. (2) *For other compounds*.—Weigh 2.00±0.02 g tech. dieldrin, dissolve in ca 200 mL CHCl<sub>3</sub>, and dil. to 250 mL with CHCl<sub>3</sub>.

(b) *Aldrin internal std soln*.—(For Diazinon®.) Weigh 4.0±0.1 g tech. aldrin into 600 mL beaker. Slurry with 400 mL acetone to dissolve, filter thru paper into 1 L vol. flask, washing with several 100 mL portions acetone, and dil. to vol. Std should be ≥90% pure and contain no impurities eluting at retention time of Diazinon.

(c) *Dibenzyl succinate internal std soln*.—(For chlorobenzilate and chloropropylate.) Weigh 5.0±0.1 g dibenzyl succinate, dissolve in ca 300 mL acetone, and dil. to 1 L with acetone. Std should be >98% pure and contain no impurities eluting at retention time for pesticide being detd.

(d) *Pesticide std solns*.—Accurately weigh 250 mg (125 mg for Diazinon and 150 mg for simazine) of ref. std of pesticide being detd (available from Ciba-Geigy Corp., PO Box 11422, Greensboro, NC 27409) into 4 oz (125 mL) round bottle with Al-lined screw cap. Pipet in 50 mL internal std soln (see Table 6:03) and shake mech. 30 min.

(e) *Diocetyl phthalate internal std soln*.—(For simazine.) Weigh 3.0±0.1 g tech. diocetyl phthalate, dissolve in ca 200 mL DMF, and dil. to 1 L with DMF. (Caution: See 51.053.) Std should be >98% pure and contain no impurities eluting at retention time of simazine.

**6.432****Preparation of Sample**

Accurately weigh amt sample specified in Table 6:03 into 4 oz (125 mL) round bottle with Al-lined screw cap. Pipet in same vol. internal std used for prepn of std soln, (d), and shake mech. 30 min. Let insol. materials settle or centr. portion of ext to obtain clear soln.

**6.433****Gas Chromatography**

Use instrument equipped with flame ionization detector and 4 mm id glass column (length specified in Table 6:03) packed with 3% Carbowax 20M (Applied Science Laboratories, Inc.) on 80–100 mesh Gas-Chrom Q. (For Diazinon, use 10% silicone DC-200 viscosity 12500.) Condition 24 hr at 240° with N or He at ca 40 mL/min. Column should have ≥2000 (≥1500 for chlorobenzilate, chloropropylate, propazine, and simazine) theoretical plates (see 6.156(a)).

Operate at following conditions: temps—as specified in Table 6:03; N or He carrier gas, 80–100 mL/min; air and H<sub>2</sub>, 80–100 mL/min; attenuation varied so that peak hts of pesticide and internal std are 60–80% full scale. Retention times are specified

**Table 6:03 Chemical and Gas Chromatographic Parameters for Triazines and Other Pesticides**

Chemical Name	Common or Trade Name	CA Registry No.	Internal Std Soln 6.431	Wt Sample	Length Column m	Temperature (°)			Retention Times (min)	
						Inlet	Column	Detector	Pesticide	Internal Std
2-(Ethylamino)-4-(isopropylamino)-6-(methylthio)-s-triazine	Ametryn	834-12-8	(a)(2)	300 mg 80% wettable powder	1.8	240	215±15	240	8-12	9-15
2-Chloro-4-(ethylamino)-6-(isopropylamino)-s-triazine	Atrazine	1912-24-9	(a)(2)	300 mg 80% wettable powder	1.8	240	200±10	240	5-7	9-15
Ethyl-4,4'-dichlorobenzilate	Chlorobenzilate	510-15-6	(c)	500 mg liq. formulation	1.2	260	230±10	260	5-8	8-10
Isopropyl-4,4'-dichlorobenzilate	Chloropropylate	5836-10-2	(c)	1 g liq. formulation	1.2	260	230±10	260	4-6	8-10
O,O-Diethyl-O-(2-isopropyl-6-methyl-4-pyrimidinyl) phosphorothioate	Diazinon	333-41-5	(b)	Sample contg 110 mg	1.8	240	190±10	240	5-6	10-12
2,4-Bis(isopropylamino)-6-methoxy-s-triazine	Prometon	1610-18-0	(a)(2)	1 g liq. formulation	1.8	240	200±20	240	3-5	9-15
2,4-Bis(isopropylamino)-6-(methylthio)-s-triazine	Prometryn	7287-19-6	(a)(2)	300 mg 80% wettable powder	1.8	240	200±10	240	6-8	9-15
2-Chloro-4,6-bis(isopropylamino)-s-triazine	Propazine	139-40-2	(a)(1)	300 mg 80% wettable powder	1.2	250	210±10	240	3-5	7-9
2-Chloro-4,6-bis(ethylamino)-s-triazine	Simazine	122-34-9	(e)	190 mg 80% wettable powder	1.8	250	210±5	250	6-8	10-14
2-(tert-Butylamino)-4-(ethylamino)-6-(methylthio)-s-triazine	Terbutryn	886-50-0	(a)(2)	300 mg 80% wettable powder	1.8	240	200±20	240	8-10	9-15

in Table 6:03. (Ametryn and dieldrin peaks must be resolved. Prep. new column if variation of flow rate or temp. does not resolve peaks. Resolution may be improved by increasing column temp.)

**6.434****Determination**

Inject 3  $\mu$ L aliquots std soln until peak ht ratio of pesticide: internal std varies  $\leq 1\%$  for successive injections. Then make duplicate injections of sample followed by duplicate injections of std. Peak ht ratios of stds must be within  $\pm 1\%$  of first accepted std values or repeat series of injections. Repeat for addnl samples.

**6.435****Calculations**

Calc. peak ht ratios for both duplicate std injections preceding and following samples. Average the 4 values ( $R'$ ). Calc. and average peak ht ratios of the 2 samples ( $R$ ).

$$\% \text{ Pesticide} = (R/W) \times (W' \times P/R'),$$

where  $W$  and  $W'$  = mg sample and std, resp.; and  $P$  = % purity of std.

**Triphenyltin Compounds (Fentin)****Potentiometric Titration Method (109)—Official First Action (CIPAC Method)****6.436****Principle**

Org. Sn compds are extd with acetone, diphenyltin compds are quant. converted to insol. oxide with alk. alumina and filtered, and acetone soln is titrd potentiometrically.

**6.437****Apparatus**

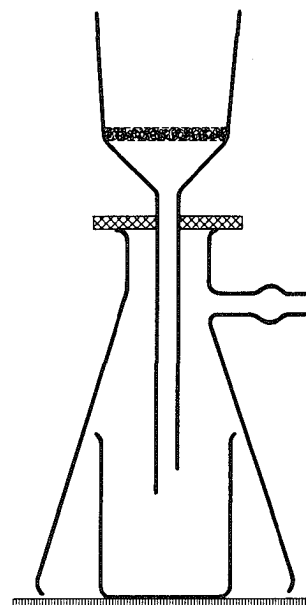

(a) *Filtration apparatus*.—Glass bell with neck and removable plate to permit glass buchner with fine porosity fritted disk and long stem to drain into beaker under vac. (Fig. 6:09).

(b) *Potentiometric titration apparatus*.—pH meter with glass and satd calomel electrodes is satisfactory.

**6.438****Reagents**

(a) *Alkaline alumina*.—Mix 150 g neutral  $\text{Al}_2\text{O}_3$  (Woelm 4649, or equiv.) with 150 mL alcohol contg 15 g KOH in 1 L r-b flask. Reflux 30 min, cool, and filter with suction thru buchner. Dry powder in vac. 1 hr at  $100^\circ$  and 3-3.5 hr at  $130^\circ$ . Pour warm powder into bottle and stopper tightly. Com. alk.  $\text{Al}_2\text{O}_3$  is not satisfactory.

(b) *Cellulose powder*.—Whatman CF 11, or equiv.

**FIG. 6:09—Filtration apparatus**

## 6.439

**Determination**

Accurately weigh into 100 mL glass beaker sample contg ca 0.30 g triphenyltin compd. Add 2 g alk.  $\text{Al}_2\text{O}_3$  and 25 mL acetone and stir with mag. stirrer 10 min. Prep. and process blank of 2 g alk.  $\text{Al}_2\text{O}_3$  and 25 mL acetone in same manner. Place 1 g cellulose powder and 1 g alk.  $\text{Al}_2\text{O}_3$  in funnel and mix thoroly. Assemble filtration app. contg 250 mL beaker and filter suspension thru funnel. Wash beaker and funnel with four 20 mL portions acetone. Titr. filtrate potentiometrically with stdzd 0.1N HCl.

$$\% \text{ Triphenyltin compd} = (S - B) \times N \times (M/W) \times 10$$

where  $S$  = mL HCl used for sample,  $B$  = mL HCl used for blank,  $N$  = normality of HCl,  $M$  = mol. wt of compd (367.0 for triphenyltin hydroxide and 409.0 for the acetate), and  $W$  = g sample.

**QUATERNARY AMMONIUM COMPOUNDS****Chloride (110)—Official Final Action****6.440 Potentiometric Titration Method**

Transfer sample contg 30–35 mg Cl to 600 mL beaker, dil. to 200 mL with  $\text{H}_2\text{O}$ , and add 5 mL  $\text{HNO}_3$  (1+1). Add just enough acetone to dissolve ppt that forms and titr. with 0.1N  $\text{AgNO}_3$ , using app. for potentiometric titrn. Calc. % Cl (1 mL 0.1N  $\text{AgNO}_3$  = 3.545 mg Cl) and equiv. % quaternary  $\text{NH}_4$  salt.

**Adsorption Indicator Method**

## 6.441

**Reagents**

(a) *Bromothymol blue indicator*.—Dissolve 1 g indicator in 500 mL 50% alcohol.

(b) *Dichlorofluorescein soln.*—0.1%. Dissolve 100 mg indicator in 100 mL 70% alcohol.

## 6.442

**Determination**

Transfer sample contg 30–140 mg Cl (usually ca 1 g quaternary  $\text{NH}_4$  salt) into 300 mL erlenmeyer, dil. to 75 mL with  $\text{H}_2\text{O}$ , and add 25 mL isopropanol. Neutze if necessary with HOAc (1+9), using 1 drop bromothymol blue (pH 4–6). Add 10 drops dichlorofluorescein, and titr. with 0.1N  $\text{AgNO}_3$ , avoiding direct sunlight. Ppt becomes red at end point and may flocculate just before end point. Calc. % Cl and equiv. % quaternary  $\text{NH}_4$  salt.

## 7. Animal Feed

### 7.001 Sampling (7)—Procedure

Use slotted single or double tube, or slotted tube and rod, all with pointed ends.

Take  $\geq 500$  g sample, 1 kg preferred, as follows: Lay bag horizontally and remove core diagonally from end to end. Det. number of cores as follows: From lots of 1–10 bags, sample all bags; from lot of  $\geq 11$ , sample 10 bags. Take 1 core from each bag sampled, except that for lots of 1–4 bags take enough diagonal cores from each bag to total  $\geq 5$  cores. For bulk feeds draw  $\geq 10$  cores from different regions; in sampling small containers ( $\leq 10$  lb) 1 package is enough. Reduce composite sample to amt required, preferably by riffing, or by mixing thoroly on clean oil-cloth or paper and quartering. Place sample in air-tight container.

A sample from less than these numbers of bags may be declared an official sample if guarantor agrees. For samples that cannot be representatively taken with probe described, use other sampling means.

### 7.002 Preparation of Sample—Official Final Action

Grind sample to pass sieve with circular openings 1 mm ( $1/25''$ ) diam. and mix thoroly. If sample cannot be ground, reduce to as fine condition as possible. Do not grind molasses feeds.

#### Moisture—Official Final Action

##### I. Drying in Vacuo at 95–100° (2)

### 7.003

#### Determination

Dry amt sample contg ca 2 g dry material to const wt at 95–100° under pressure  $\leq 100$  mm Hg (ca 5 hr). For feeds with high molasses content, use temp.  $\leq 70^\circ$  and pressure  $\leq 50$  mm Hg. Use covered Al dish  $\geq 50$  mm diam. and  $\leq 40$  mm deep. Report loss in wt as moisture.

##### II. By Distillation with Toluene (3)

### 7.004

#### Apparatus

Connect 250 mL flask of Pyrex or other resistant glass by means of Bidwell-Sterling moisture receiver to 500 mm Liebig condenser. Calibrate receiver, 5 mL capacity, by distg known amts  $H_2O$  into graduated column, and estg column of  $H_2O$  to 0.01 mL. Clean tube and condenser with chromic acid cleaning mixt., rinse thoroly with  $H_2O$ , then alcohol, and dry in oven to prevent undue amt  $H_2O$  from adhering to inner surfaces during detn.

### 7.005

#### Determination

If sample is likely to bump, add dry sand to cover bottom of flask. Add enough toluene to cover sample completely (ca 75 mL). Weigh and introduce enough sample into toluene to give 2–5 mL  $H_2O$  and connect app. Fill receiving tube with toluene, pouring it thru top of condenser. Bring to boil and distil slowly, ca 2 drops/sec, until most of the  $H_2O$  passes over; then increase rate of distn to ca 4 drops/sec.

When all  $H_2O$  is apparently over, wash down condenser by pouring toluene in at top, continuing distn short time to see whether any more  $H_2O$  distils over; if it does, repeat washing-down process. If any  $H_2O$  remains in condenser, remove by

brushing down with tube brush attached to Cu wire and satd with toluene, washing down condenser at same time. (Entire process is usually completed within 1 hr.) Let receiving tube come to room temp. If any drops adhere to sides of tube, force them down, using Cu wire with end wrapped with rubber band. Read vol.  $H_2O$  and calc. to %.

### 7.006 ★ III. Drying without Heat over ★ Sulfuric Acid (4)

See 7.006–7.007, 12th ed.

### 7.007 IV. Drying at 135° (5)

(Not to be used when fat detn is to be made on same sample)

Regulate air oven to  $135 \pm 2^\circ$ . Using low, covered Al dishes, 7.003, weigh ca 2 g sample into each dish and shake until contents are evenly distributed. With covers removed, place dishes and covers in oven as quickly as possible and dry samples 2 hr. Place covers on dishes and transfer to desiccator to cool. Weigh, and calc. loss in wt as  $H_2O$ .

### 7.008 V. In Highly Acid Milk By-products (6)

Add ca 2 g  $ZnO$ , freshly ignited or oven dried, to flat-bottom dish  $\geq 5$  cm diam. and weigh. Add ca 1 g sample and weigh quickly. Add ca 5 mL  $H_2O$  and distribute sample evenly on bottom of dish. Heat on steam bath, exposing max. surface of dish bottom to live steam until apparently dry. Heat at 98–100° in air oven 3 hr or to const wt. Cool in desiccator; then weigh quickly. Det. wt residue. Tit. acidity of sample and calc. as lactic acid, 16.023. To compensate for  $H_2O$  formed when acid is neutrd by  $ZnO$ , add 0.1 g to residue wt for each g acid (as lactic) in weighed sample. Report % residue (corrected) as total solids.

### 7.009 Ash (7)—Official Final Action

Weigh 2 g sample into porcelain crucible and place in temp. controlled furnace preheated to 600°. Hold at this temp. 2 hr. Transfer crucible directly to desiccator, cool, and weigh immediately, reporting % ash to first decimal place.

## NITROGEN

### Qualitative Tests for Proteins (8)—Official Final Action

### 7.010 ★ Biuret Test ★

See 22.012–22.013, 10th ed.

### 7.011 ★ Millon Test ★

See 22.014–22.015, 10th ed. (Caution: See 51.018, 51.026, and 51.065.)

### 7.012 ★ Glyoxylic Acid Test (Hopkins-Cole) ★

See 22.016–22.017, 10th ed. (Caution: Wear face shield and heavy rubber gloves as protection against reagent bump. See also 51.018 and 51.063.)

★ Surplus method—see inside front cover.

**7.013 ★ Adamkiewicz Test ★**

See 22.018, 10th ed.

**7.014 ★ Xanthoproteic Test ★**

See 22.019, 10th ed.

**Crude Protein—Official Final Action****7.015 Kjeldahl Method (9)**

Det. N as in 2.057. Multiply result by 6.25, or in case of wheat grains by 5.70.

**Dumas Method (10)****7.016****Principle**

N, freed by pyrolysis and subsequent combustions, is swept by CO<sub>2</sub> carrier into nitrometer. CO<sub>2</sub> is absorbed in KOH and vol. residual N is measured and converted to equiv. protein by numerical factor.

**7.017****Apparatus and Reagents**

(a) *Nitrogen analyzer and accessories.*—Consists of combustion and collection and measuring systems. Suitable instrument, Model 29A, with following accessories and reagents is available from Coleman Instruments Div., 2000 York Rd, Oak Brook, IL 60521: Al combustion boats, No. 29-412; Vycor combustion tubes, No. 29-328; CuO-Pt catalyst (CuO wire form with 2.5% Pt reforming catalyst), No. 29-160; reduced Cu wire, No. 29-120; Co<sub>3</sub>O<sub>4</sub>, No. 29-170; CuO powder, fines, No. 29-140; 45% KOH, No. 29-110.

(b) *Balance.*—Accurate to 0.01 mg.

(c) *Barometer.*—Hg type, readable to 0.1 mm.

**7.018****Preparation of Samples**

Grind to pass No. 30 sieve. Store in capped bottles.

**7.019****Determination**

Operate instrument in accordance with instructions of manufacturer. (Following directions apply to Coleman Model 29A Nitrogen Analyzer. Consult Operating Directions D-360B, Coleman Cat. No. 29-904, for addnl details.)

After combustion furnaces have come to thermal equilibrium, turn combustion cycle control to START and let proceed normally thru cycle. Observe indicated temp. on pyrometer of both upper and lower combustion furnaces at end of combustion portion of cycle. Furnace temps should be 850–900°. If not, adjust.

Prep. combustion tube by inserting stainless steel screen in lower end of combustion tube (end farthest from trademark). In upper end, place enough glass wool to form 6 mm plug when packed. With 11 mm glass rod, drive glass wool down to stainless steel plug. Holding tube vertically, pour CuO-Pt catalyst directly from dispenser bottle into combustion tube until it reaches upper end of trademark. Tap or vibrate tube on bench until reagent settles to approx. center of trademark.

Weigh and record wt of empty Al combustion boat. Place sample in boat. Weigh and record wt of sample and combustion boat. Difference between wts is sample wt. Use following sample wts (mg) as guides to suitable sample sizes: bermuda grass 150–300; rice bran, wheat shorts, dehydrated alfalfa 150–250; range feed 100–200; cottonseed meal 75–150; edible soy protein 50–150. Weigh sample to nearest 0.01 mg. To avoid wt changes,

**Table 7:01 Volume correction for temperature correction factor ( $C_t$ ) ( $\mu\text{L}/^\circ\text{K}$ )<sup>a</sup>**

Final Counter Reading ( $\mu\text{L}$ )	( $C_t$ ) (Nitrometers with Check Value)
0	12
5000	29
10000	45
15000	62
20000	79
25000	95
30000	112
35000	129
40000	145
45000	162
50000	179

<sup>a</sup> Vol. correction,  $V_t = C_t(t_2 - t_1)$

record wt within 1 min after sample and boat are placed on balance. If this is impossible, weigh sample inside weighing bottle, such as Kimble No. 15165 or 15166.

Turn combustion tube to horizontal, and carefully insert loaded sample boat into open end of tube. Slide or push boat, without spilling contents, until it reaches trademark. Raise open end until tube forms 60–70° angle to horizontal. Tap or vibrate combustion tube on bench top while rotating tube between thumb and forefinger. Raise open end of tube and add vol. Co<sub>3</sub>O<sub>4</sub> and vol. CuO fines equal to vol. sample. For convenient means of adding above reagents to samples, place vol. CuO fines and vol. Co<sub>3</sub>O<sub>4</sub>, each equal to vol. sample, in addnl combustion boat; add contents of boat, but not boat itself, to combustion tube; and rotate partially filled combustion tube between thumb and forefinger while varying angle of tube 20–45° from horizontal. Continue rotating, tapping, and vibrating until sample is dispelled from boat and is thoroly mixed with oxidizing agents. Raise open end until tube forms 60–70° angle to horizontal; add CuO-Pt catalyst ca 12 mm above sample boat. Tap or vibrate gently to eliminate voids. Add CuO-Pt catalyst to within 20 mm of top of tube, again tapping or vibrating gently to eliminate voids.

Install prep combustion tube in N analyzer. Adjust 45% KOH soln meniscus to calibrating mark in nitrometer with digital readout meter. Record counter reading,  $R_1$ . (Counter reading should preferably lie between 500 and 1000  $\mu\text{L}$  at this point. Vent control may be used to assist in arriving at this counter setting, if necessary.) Record syringe temp.,  $t_1$ , indicated on special scale thermometer. Add 2 min more to combustion portion of cycle by turning auxiliary timer to setting 3. (Once this is done, addnl 2 min will be automatically programmed into each subsequent cycle.) Turn combustion cycle control to START. Let analyzer proceed thru its cycle. After cycle is complete and combustion cycle control has entered STAND-BY section, readjust KOH meniscus to calibration mark with digital readout counter. Record new counter reading,  $R_2$ , and syringe temp.,  $t_2$ . Det. blank for instrument under same conditions as actual analysis except omit sample.

**Table 7:02 Barometric temperature correction ( $P_o$ )**

Temperature, °C	$P_o$ (mm Hg)	
	700–749	750–780
10	1.2	1.3
15	1.8	1.9
20	2.3	2.5
25	2.9	3.1
30	3.5	3.7
35	4.1	4.3

★ Surplus method—see inside front cover.

## 7.020

## Calculations

(a) Record observed N vol.,  $V_o = R_2 - R_1$ , where  $V_o$  = observed N vol. ( $\mu\text{L}$ ),  $R_1$  = initial counter reading, and  $R_2$  = final counter reading.

(b) Det. corrected N vol. (in  $\mu\text{L}$ ),  $V_c = V_o - (V_b + V_t)$ , where  $V_b$  = vol. blank ( $\mu\text{L}$ ),  $V_t$  = vol. correction for temp. ( $\mu\text{L}$ ) =  $C_t(t_2 - t_1)$ .  $C_t$  is obtained from Table 7:01 (based on final counter reading);  $t_2$  and  $t_1$  are in  $^{\circ}\text{K}$ .

(c) Det. corrected barometric pressure,  $P_c = P_o - (P_b + P_v)$ , where  $P_o$  = observed barometric pressure (mm Hg),  $P_b$  = barometric temp. correction (from Table 7:02), and  $P_v$  = pressure correction for vapor pressure of KOH soln (from Table 7:03).

(Note: Empirical approximation of  $(P_b + P_v) = 11.0$  will be satisfactorily accurate for  $P_o$  between 740 and 780 mm Hg and syringe temp. between 298 and 305 $^{\circ}\text{K}$ .)

(d) Calc. % N =  $(P_c \times V_c \times 0.0449)/(T \times W)$ , where  $T$  = final syringe temp. in  $^{\circ}\text{K}$  and  $W$  = sample wt in mg.

## Example:

$P_o = 750.1$  mm Hg at 25 $^{\circ}\text{C}$ ;  $W = 148.91$  mg

	Start	Finish
Counter readings, blank	500 $\mu\text{L}$	524 $\mu\text{L}$
Counter readings, sample	524	6955
$t_1 = 302.7^{\circ}\text{K}$ , $t_2 = 303.0^{\circ}\text{K}$ , $V_o = 6955 - 524 = 6431 \mu\text{L}$		
$V_c = 6431 - [24 + C_t(t_2 - t_1)] = 6431 - (24 + 35 \times 0.3) = 6396 \mu\text{L}$		

$P_c = 750.1 - (3.1 \times 9.6) = 737.4$

% N =  $(737.4 \times 6396 \times 0.04493)/(303.0 \times 148.91) = 4.69\%$

(e) Calc. % protein = % N  $\times$  6.25, or % N  $\times$  5.70 in case of wheat grains.

**Table 7:03 Pressure correction ( $P_v$ ) for vapor pressure of KOH (for practical purposes, temp. of KOH is same as syringe)**

Temperature, $^{\circ}\text{K}$	$P_v$ (mm Hg)
288	4.1
293	5.7
298	7.4
303	9.6
308	12.5
313	16.5

## Automated Method (11)—Official Final Action

## 7.021

## Principle

Automation of macro Kjeldahl method is in 6 steps: sample and reagent addn, initial and final digestion, cooling and diln, NaOH addn, steam distn and titrn, and automatic pumping of flask contents to waste. Chemistry is carried out in macro Kjeldahl flasks equipped with side arms which are rotated at 3 min intervals thru each successive step.

## 7.022

## Apparatus

(a) *Kjeldahl (protein/nitrogen) analyzer*.—Kjel-Foss Automatic, Model 16210 (Foss America, Inc., PO Box 504, Rt 82, Fishkill, NY 12524), or equiv.

(b) *Weighing papers*.—120  $\times$  120 mm N-free tissues, Foss America, Inc., or equiv.

## 7.023

## Reagents

(a) *Kjel-tabs*.—Contg 5 g  $\text{K}_2\text{SO}_4$  and 0.25 g  $\text{HgO}$  (Foss America, Inc.).

(b) *Kjeldahl (protein/nitrogen) analyzer reagents*.—Prep. following according to manufacturer's instructions: (1) *Sulfuric*

*acid*.—96–98%. (2) *Hydrogen peroxide*.—30–35%. (3) *Ammonium sulfate std solns*.—(a) *Std soln I*.—Dissolve 30.000 $\pm$ 0.030 g  $(\text{NH}_4)_2\text{SO}_4$  in  $\text{H}_2\text{O}$  and dil. to 1 L with  $\text{H}_2\text{O}$ . (b) *Std soln II*.—Dissolve 0.750 $\pm$ 0.001 g  $(\text{NH}_4)_2\text{SO}_4$  in  $\text{H}_2\text{O}$  and dil. to 1 L with  $\text{H}_2\text{O}$ . (4) *Mixed indicator soln*.—Dissolve 1.000 g Me red and 0.250 g methylene blue in alcohol and dil. to 1 L with alcohol. Dil. 10 mL this soln to 1 L with  $\text{H}_2\text{O}$ . (5) *Sodium hydroxide-sodium thiosulfate soln*.—40% NaOH-8%  $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ . (6) *Dilute sulfuric acid soln*.—0.6%. Dil. 30 mL 96–98%  $\text{H}_2\text{SO}_4$  to 5 L with  $\text{H}_2\text{O}$ .

## 7.024

## Determination

(Caution: See 51.019, 51.030, 51.065, and 51.070.)

Place 3 Kjel-tabs in special flask (500 mL of design compatible to Foss instrument) in position 1. Shift dispenser arm over flask and depress  $\text{H}_2\text{SO}_4$  lever, initiating simultaneous addn of 10 mL 30–35%  $\text{H}_2\text{O}_2$  and 12–15 mL 96–98%  $\text{H}_2\text{SO}_4$  (depending on fat content of sample). To flask, add accurately weighed sample (ca 1.0 g if <45% protein, and ca 0.5 g if >45% protein) wrapped in weighing paper and close lid. Flask automatically rotates to position 2 where sample digests 3 min, and then to position 3 for 3 min addnl digestion. In position 4, flask is cooled by centrifugal blower, lid opens automatically, and 140 mL  $\text{H}_2\text{O}$  is added automatically. Flask rotates to position 5, where NaOH- $\text{Na}_2\text{S}_2\text{O}_3$  soln is automatically introduced in excess. Released  $\text{NH}_3$  is steam distd quant. into 200 mL tall-form titrn beaker contg 50 mL mixed indicator soln, and is simultaneously titrd automatically with dil.  $\text{H}_2\text{SO}_4$  soln delivered by photometrically regulated syringe. Final position of syringe is measured by potentiometer, output of which feeds electronic circuitry for conversion to visual display and/or printout in % N or % protein with appropriate conversion factors. In position 6, flask is emptied. Calibrate instrument initially each day with aliquots of  $(\text{NH}_4)_2\text{SO}_4$  std solns and check periodically as stated in operating manual.

## Semiautomated Method (12)—Official Final Action

## 7.025

## Principle

Samples are digested in 250 mL calibrated tubes, using block digester. A of  $\text{NH}_3$ -salicylate complex is read in flowcell at 660 nm, or  $\text{NH}_3$  is distd into std acid and back-titrd with std alkali.

## 7.026

## Apparatus

(a) *Block digester*.—Model BD-20 (Technicon Instruments Corp.) or Model DS-20 (Tecator, Inc., 1898 S Flatiron Ct, Boulder, CO 80301). Capable of maintaining 410 $^{\circ}$  and digesting 20 samples at a time in 250 mL calibrated volumetric tubes constricted at top. Block must be equipped with removable shields to enclose exposed area of tubes completely at or above ht of constriction.

(b) *Automatic analyzer*.—AutoAnalyzer with following modules (Technicon Instruments Corp.), or equiv.: Sampler II or IV with 40/hr (2:1) cam (higher ratio cams result in carry-over and poorer peak sepn); proportioning pump III;  $\text{NH}_3$  anal. cartridge No. 116-D531-01 (or construct equiv. manifold from flow diagram); AAL single channel colorimeter with 15  $\times$  1.5–2.0 mm id tubular flowcell, matched 660 nm interference filters, and voltage stabilizer; and recorder of appropriate span. (See Fig. 7:01.)

## 7.027

## Reagents

(a) *Phosphate-tartrate buffer soln*.—pH 14.0. Dissolve 50 g NaK tartrate and 26.8 g  $\text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O}$  in 600 mL  $\text{H}_2\text{O}$ . Add 54 g NaOH and dissolve. Add 1 mL Brij-35 (Technicon Instruments Corp.), dil. to 1 L with  $\text{H}_2\text{O}$ , and mix.

(b) *Sodium chloride-sulfuric acid soln.*—Dissolve 200 g NaCl in H<sub>2</sub>O in 2 L vol. flask. Add 15 mL H<sub>2</sub>SO<sub>4</sub> and 2 mL Brij-35. Dil. to vol. with H<sub>2</sub>O and mix.

(c) *Sodium hypochlorite soln.*—Dil. 6 mL com. bleach soln contg 5.25% available Cl (Clorox, or equiv.) to 100 mL with H<sub>2</sub>O and mix. Prep. fresh daily.

(d) *Sodium nitroprusside-sodium salicylate soln.*—Dissolve 150 g NaC<sub>2</sub>H<sub>3</sub>O<sub>3</sub> and 0.3 g Na<sub>2</sub>Fe(CN)<sub>5</sub>.NO.2H<sub>2</sub>O in 600 mL H<sub>2</sub>O. Add 1 mL Brij-35, dil. to 1 L with H<sub>2</sub>O, and mix.

(e) *Nitrogen std solns.*—Prep. 6 stds by accurately weighing ( $\pm 10$  mg) 59, 118, 177, 236, 295, and 354 mg (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> primary std (Fisher Scientific Co. No. A-938, or equiv.; dry 2 hr at 105° before use and assume theoretical value of 21.20% N after drying) into individual 250 mL digestion tubes. Proceed as in 7.031, beginning "Add 9 g K<sub>2</sub>SO<sub>4</sub>, 0.42 g HgO, and 15 mL H<sub>2</sub>SO<sub>4</sub> . . ." Std's may be stored and reused until exhausted.

(f) *Sodium hydroxide-potassium sulfide soln.*—Dissolve 400 g NaOH in H<sub>2</sub>O. While still warm, dissolve 30 g K<sub>2</sub>S in soln, and dil. to 1 L.

## 7.028

## Analytical System

If manifold is to be constructed, use clear std pump tubes for all air and soln flows. All fittings, coils, and glass transmission lines are AAll type and size. Use glass transmission tubing for all connections after pump to colorimeter. Construct modified AO fitting on sample diln loop using AO fitting, N13 stainless steel nipple connector, and  $\frac{1}{2}$ " length of 0.035" id Tygon tubing. Insert N13 nipple approx. halfway into 0.035" Tygon tubing. Insert tubing into side arm of AO fitting far enough so resample line will not pump any air. Space pump tubes equally across pump rollers. Cut 0.16 mL/min resample pump tube  $\leq 1$ " at entrance before connecting to side arm of AO fitting. In operation, add buffer and hypochlorite solns thru metal side arms of A10 type fittings; add salicylate soln, (d), thru metal insert to 20T coil. Air, reagents, and sample are combined immediately after pump thru injection fittings.

## 7.029

## Start-Up

Start automatic system and place all lines except salicylate line in resp. solns. After  $\geq 5$  min, place salicylate line in resp. soln and let system equilibrate. If ppt forms after addn of salicylate, pH is too low. Immediately stop proportioning pump and flush coils with H<sub>2</sub>O, using syringe. Before restarting system, check concns of NaCl-H<sub>2</sub>SO<sub>4</sub> soln and phosphate-tartrate buffer soln.

Pump lowest concn N std soln continuously thru system  $\geq 5$  min and adjust baseline control on colorimeter to read 10% full scale. Pump highest concn N std soln continuously thru system until no drift exists (usually  $\geq 10$  min) and adjust "std. cal." control to read 85% full scale. Recorder tracings must be stable and show  $< 0.3$  division noise. If noisy conditions exist, replace dialyzer membrane. When recorder tracing indicates stable condition, immediately start sampling.

## 7.030

## Shut-Down

Place reagent lines in H<sub>2</sub>O, removing salicylate line first. Let system wash out  $\geq 20$  min.

## 7.031

## Colorimetric Determination

(Caution: See 51.065.)

Weigh samples (See Table 7.04) into dry digestion tubes. Add 9 g K<sub>2</sub>SO<sub>4</sub>, 0.42 g HgO, and 15 mL H<sub>2</sub>SO<sub>4</sub> to each tube. (Calibrated metal scoops may be used for solids.) Insert tubes into digester block preheated to 410°, place shields around tubes, and digest 45 min.

After digestion, remove rack of tubes from block, place in hood, and let cool 8–10 min. (Time depends upon air flow around tubes.) Direct rapid spray of H<sub>2</sub>O (kitchen sink dish rinsing sprayer works well) to bottom of each tube to dissolve acid digest completely. If ppt forms, place tube in ultrasonic bath to aid in redissolving salt. Let cool, dil. to vol., and mix thoroly. Transfer portion of each sample soln to AutoAnalyzer beaker.

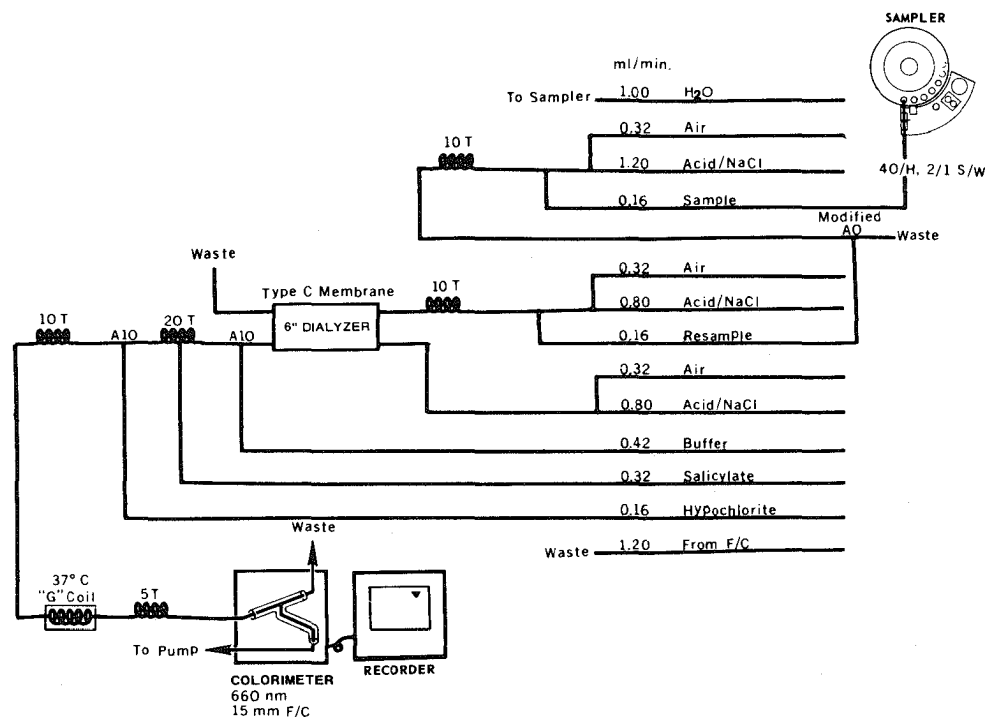

FIG. 7.01—Flow diagram for semiautomated analysis for crude protein

Table 7:04 Sample Weight

Protein, %	Sample, g
6–24	1.5±0.1
25–40	1.0±0.1
41–50	0.8±0.1
51–60	0.7±0.1
61–90	0.5±0.01
>90	Weigh sample equiv. to 50 mg N

Place stds in tray in increasing order of concn, followed by group of samples. Analyze lowest concn std in duplicate, discarding first peak. Precede and follow each group of samples with std ref. curve to correct for possible drift. Analyze stds and samples at rate of 40/hr, 2/1 sample-to-wash ratio. Prep. std curve by averaging peak hts of first and second set of stds. Plot av. peak ht stds against N concn contained in each 250 mL tube.

$$\% \text{ Protein} = [(\text{mg N}/250 \text{ mL from graph}) \times 6.25 \times 100]/\text{mg sample}$$

## 7.032

## Titrimetric Determination

Digest as in 7.031. Cool 5 min and add only enough H<sub>2</sub>O to dissolve salts (70–75 mL). Cool and attach digestion tube to distn head according to manufacturer's directions. Place receiver flask contg 25 mL std acid, 2.055(j), and 5–7 drops Me red indicator on platform. Condenser tip must be below surface of std acid soln. Add 50 mL NaOH-K<sub>2</sub>S soln to tube and steam distil vigorously until 125 mL distillate collects. Titr. excess acid with std 0.1N NaOH soln, 2.055(k). Correct for reagent blank.

$$\% \text{ N} = [(\text{mL std acid} \times \text{normality acid}) - (\text{mL std NaOH} \times \text{normality NaOH})] \times 1.4007/\text{g sample}$$

$$\% \text{ crude protein} = \% \text{ N} \times 6.25$$

### Urea and Ammoniacal Nitrogen (73) Official Final Action

## 7.033

## Reagents

(a) *Defoaming soln.*—Dow Corning Corp. Antifoam B Emulsion.

(b) *Urease soln.*—Prep. fresh soln by dissolving stdzd urease in H<sub>2</sub>O so that each 10 mL neutzd soln will convert N of ≥0.1 g pure urea.

*Standardization.*—To det. alky of com. urease prepn dissolve 0.1 g in 50 mL H<sub>2</sub>O and titr. with 0.1N HCl, using Me red, 2.055(i). Add same vol. 0.1N HCl to each 0.1 g urease in prepg urease soln. To det. enzyme activity, prep. ca 50 mL neutzd 1% soln. Add different amts of soln to 0.1 g samples pure urea and follow with enzyme digestion and distn as in detn. Calc. activity of urease prepn from amt of this urease soln that completely converted urea, as detd by complete recovery of N by distn.

(c) *Calcium chloride soln.*—Dissolve 25 g CaCl<sub>2</sub> in 100 mL H<sub>2</sub>O.

## 7.034

## Determination

Place 2 g sample in Kjeldahl flask with ca 250 mL H<sub>2</sub>O. Add 10 mL urease soln, stopper tightly, and let stand 1 hr at room temp. or 20 min at 40°. Cool to room temp. if necessary. Use addnl urease soln if feed contains >5% urea (ca 12% protein equiv.). Rinse stopper and neck with few mL H<sub>2</sub>O. Add ≥2 g MgO (heavy type), 5 mL CaCl<sub>2</sub> soln, and 3 mL defoaming soln, and connect flask with condenser by Kjeldahl connecting bulb. Distil 100 mL into measured vol. std acid, 2.055(j), and titr. with std alkali, 2.055(k), using Me red, 2.055(i).

★ Surplus method—see inside front cover.

## Urea (74)—Official Final Action

(Applicable to animal feeds and their ingredients)

## 7.035

## Apparatus

*Spectrophotometer.*—Instrument with max. band width 2.4 nm at 420 nm, with 1 cm cells.

## 7.036

## Reagents

(a) *p-Dimethylaminobenzaldehyde (DMAB) soln.*—Dissolve 16.00 g (Eastman Kodak Co. No. 95 only) in 1 L alcohol and add 100 mL HCl. Stable 1 month. Prep. new std curve with each new batch of reagent.

(b) *Zinc acetate soln.*—Dissolve 22.0 g Zn(OAc)<sub>2</sub>·2H<sub>2</sub>O in H<sub>2</sub>O, add 3 mL HOAc, and dil. to 100 mL.

(c) *Potassium ferrocyanide soln.*—Dissolve 10.6 g K<sub>4</sub>Fe(CN)<sub>6</sub>·3H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL.

(d) *Vegetable charcoal.*—Darco G-60.

(e) *Phosphate buffer soln.*—pH 7.0. Dissolve 3.403 g anhyd. KH<sub>2</sub>PO<sub>4</sub> and 4.355 g anhyd. K<sub>2</sub>HPO<sub>4</sub> sep. in ca 100 mL portions freshly distd H<sub>2</sub>O. Combine solns and dil. to 1 L with H<sub>2</sub>O.

(f) *Urea std solns.*—(1) *Stock soln.*—5 mg/mL. Dissolve 5.000±0.001 g reagent grade urea in H<sub>2</sub>O and dil. to 1 L with H<sub>2</sub>O. (2) *Working solns.*—0.2, 0.4, 0.6, 0.8, 1.0, 1.2, 1.4, 1.6, 1.8, and 2.0 mg urea/5 mL. Pipet 2, 4, 6, 8, 10, 12, 14, 16, 18, and 20 mL stock soln into 250 mL vol. flasks and dil. to vol. with phosphate buffer. (3) *Reference soln.*—Use std soln contg 1.0 mg urea/5 mL as ref. std. Store at <24°. Stable 1 week.

## 7.037

## Preparation of Standard Curve

Pipet 5 mL aliquots of working std solns into 20 × 150 mm (25 mL) test tubes and add 5 mL DMAB soln to each. Prep. reagent blank of 5 mL buffer soln and 5 mL DMAB soln. Shake tubes thoroly and let stand 10 min in H<sub>2</sub>O bath at 25°. Read A in 1 cm cell at 420 nm with reagent blank at zero A. Plot A against concn urea. Plot should be straight line; if not, repeat, using new lot of DMAB.

## 7.038

## Determination

Weigh 1.00 g ground sample into 500 mL vol. flask. Add 1 g charcoal, ca 250 mL H<sub>2</sub>O, 5 mL Zn(OAc)<sub>2</sub> soln, and 5 mL K<sub>4</sub>Fe(CN)<sub>6</sub> soln. Shake mech. 30 min and dil. to vol. with H<sub>2</sub>O. Let stand until ppt settles. Decant thru Whatman No. 40 paper and collect clear filtrate. Pipet 5 mL filtrate into test tube, add 5 mL DMAB soln, and shake thoroly. Include reference std (5 mL soln (f)(3) and 5 mL DMAB soln) and reagent blank with each group of samples. Let stand 10 min in H<sub>2</sub>O bath at 25°. Read A at 420 nm against reagent blank.

$$\% \text{ Urea} = (1.0 \times A_{\text{sample}} \times 100)/(A_{\text{std}} \times \text{mg sample in aliquot}).$$

## 7.039 ★ Albuminoid Nitrogen—Official Final Action ★

Pptn with Cu(OH)<sub>2</sub> and N detn. See 22.020–22.021, 10th ed.

## 7.040 ★ Amido Nitrogen—Official Final Action ★

$$\% \text{ total N} - \% \text{ albuminoid N} = \% \text{ amido N.}$$

## Nitrate and Nitrite Nitrogen (75)—Official Final Action

## 7.041

## Principle

Nitrate and nitrite are extd with Cd and Ba chloride soln. Bulk of sol. proteins are pptd in alk. soln and clarified soln is passed thru metallic Cd column, reducing nitrate to nitrite. Nitrite is measured colorimetrically. (Caution: Cd salts are toxic. See 51.084.)

## 7.042

**Reagents and Apparatus**

(a) *Nitrate nitrogen std solns.*—(1) *Stock soln.*—12  $\mu\text{g}$  nitrate N/mL. Dissolve 0.867 g  $\text{KNO}_3$  in 1 L  $\text{H}_2\text{O}$ . Dil. 25 mL to 250 mL with  $\text{H}_2\text{O}$ . (2) *Working solns.*—0.6, 1.2, 1.8, 2.4, 3.0  $\mu\text{g}$  N/mL. Dil. 5, 10, 15, 20, and 25 mL stock soln to 100 mL with  $\text{H}_2\text{O}$ .

(b) *Extracting soln.*—Dissolve and dil. 50 g  $\text{CdCl}_2$  and 50 g  $\text{BaCl}_2$  to 1 L with  $\text{H}_2\text{O}$ . Adjust to pH 1 with HCl.

(c) *Ammonium chloride buffer soln.*—pH 9.6. Dissolve 50 g  $\text{NH}_4\text{Cl}$  in 500 mL  $\text{H}_2\text{O}$  and adjust pH with  $\text{NH}_4\text{OH}$ . Dil. to 1 L with  $\text{H}_2\text{O}$ .

(d) *Sodium hydroxide soln.*—2.5*N*. Dissolve 50 g NaOH in 500 mL  $\text{H}_2\text{O}$ .

(e) *Sulfanilamide soln.*—0.5%. Dissolve 1.25 g sulfanilamide in 250 mL HCl (1+1). Soln is stable 1–2 months.

(f) *Coupling reagent.*—Dissolve 0.5 g N(1-naphthyl)ethylene-diamine.HCl in 100 mL  $\text{H}_2\text{O}$ . Store in g-s dark bottle in refrigerator. Soln is stable several weeks.

(g) *Salt soln.*—Dissolve 100 g NaCl in 500 mL  $\text{H}_2\text{O}$ . Add 50 mL buffer soln, (c), and dil. to 1 L with  $\text{H}_2\text{O}$ .

(h) *Reduction tube.*—25 mL buret or equiv. id chromatgc tube with stopcock and reservoir (Kontes Glass Co. Cat. No. K-420280 or SGA Scientific Inc. Cat. No. JC-1506).

## 7.043

**Preparation of Columns**

Prep. supply of metallic Cd by placing Zn rods into 500 mL 20%  $\text{CdSO}_4$  soln. After reaction for 3 hr, discard soln and scrape moss-like Cd growth from Zn rods. Place Cd in high-speed blender, add 500 mL  $\text{H}_2\text{O}$ , and blend 2 sec. Wash fine metal particles with  $\text{H}_2\text{O}$  onto sieves, collecting only 20–40 mesh size. Fill reduction tube with  $\text{H}_2\text{O}$  and add 2 cm plug of glass wool. Press any trapped air from glass wool as it is pushed to bottom of column with glass rod. Add Cd to depth of 10 cm, using min. of very gentle tapping. Wash column with 25 mL 0.10*N* HCl, two 25 mL portions  $\text{H}_2\text{O}$ , and finally 25 mL buffer, (c), dild 1 + 9. Keep column covered with salt soln, (g), when not in use.

Normally columns can be used repeatedly if kept under salt soln between analyses. When succession of highly proteinaceous or other sol. org. contg samples are treated, flow rate may decrease gradually. Repeating 25 mL 0.10*N* HCl treatment may restore original flow rate; if not, prep. new column. Reproducible flow rate is important. Actual rate can be 3–5 mL/min but once established, it must be identical ( $\pm 0.1$  mL) for samples and stds.

## 7.044

**Preparation of Standard Curve**

Prep. std curve of 3, 6, 9, 12, and 15  $\mu\text{g}$  nitrate-nitrite N by pipetting 5.0 mL aliquots of working std solns into 30 mL beakers. Add 5 mL buffer soln, (c), and 15 mL  $\text{H}_2\text{O}$ , mix well, and transfer quant. to reduction column, using min.  $\text{H}_2\text{O}$ . Adjust flow rate thru column to 3–5 mL/min. Just as reservoir empties, add 15 mL salt soln, (g). Collect eluate, including salt wash, in 50 mL vol. flask (total vol. of eluate should be ca 40 mL). Add 5 mL sulfanilamide soln, (e), mix, and let stand 3 min. Add 2 mL coupling reagent, (f), mix, dil. to vol. with  $\text{H}_2\text{O}$ , mix, and let stand 20 min for max. color development. Color is stable  $\geq 2$  hr. Det. A in 1 cm cells at 540 nm against reagent blank. Plot A against  $\mu\text{g}$  nitrate-nitrite N.

## 7.045

**Extraction**

(a) *Low level nitrate samples (grains, meals, supplements, etc.).*—Wash 5.0 g finely ground sample into 250 mL vol. flask. Add 100 mL extg soln, (b), and 100 mL  $\text{H}_2\text{O}$ , and mix. Let stand 1 hr with occasional swirling. Add 20 mL 2.5*N* NaOH, dil. to vol. with  $\text{H}_2\text{O}$ , mix, and filter immediately thru rapid paper. Pipet 10

mL buffer soln, (c), into 100 mL vol. flask, dil. to vol. with clear filtrate, and mix.

(b) *Dry, high level nitrate products (dried plants, hays, meals, etc.).*—Weigh 5.0 g finely ground sample into 500 mL vol. flask. Add 100 mL extg soln, (b), and 300 mL  $\text{H}_2\text{O}$ , and mix. Let stand 1 hr with occasional swirling, add 40 mL 2.5*N* NaOH, dil. to vol. with  $\text{H}_2\text{O}$ , mix, and filter immediately thru rapid paper. Pipet 10 mL buffer soln, (c), into 100 mL vol. flask, dil. to vol. with clear filtrate, and mix.

(c) *Grasses, silages, and other wet materials.*—Weigh 100 g sample into 1 gal. capacity high-speed blender. Add 100 mL extg soln, (b), and 800 mL  $\text{H}_2\text{O}$ , including vol.  $\text{H}_2\text{O}$  contributed by sample as detd in 7.003 or 7.005. Homogenize 1 min, pour into 2 L beaker, and let stand 1 hr. Add 100 mL buffer soln, (c) (total vol. 1 L), mix well, and filter thru Whatman No. 42 paper, collecting portion of clear filtrate.

## 7.046

**Determination**

(a) *Nitrate plus nitrite nitrogen.*—Pipet 25 mL buffered sample exts, 7.045(a) or (b), or 5 mL ext, (c), into reduction column and treat as in 7.044, beginning, "Adjust flow rate thru column . . ." Rinse column with 30 mL  $\text{H}_2\text{O}$  between samples to remove NaCl. Use portion of buffered sample exts with equiv. diln and pH as ref. soln in detg A at 540 nm. Also det. nitrate-nitrite in reagents and correct for this blank value. Calc. total nitrate-nitrite N from std curve.

(b) *Nitrite nitrogen.*—Pipet aliquot clear sample filtrate (contg  $< 15 \mu\text{g}$  nitrite) into 50 mL vol. flask and dil. with  $\text{H}_2\text{O}$  to ca 40 mL. Mix well, add 5 mL sulfanilamide soln, (e), mix, and let stand 3 min. Add 2 mL coupling reagent, (f), and dil. to vol. with  $\text{H}_2\text{O}$ . Mix well and let stand 20 min for max. color development. Measure A in 1 cm cells against sample ext with equiv. diln at 540 nm. Correct for nitrite reagent blank.

(c) *Nitrate nitrogen.*—Calc. by difference between (a) and (b) above.

## 7.047

**Calculation**

ppm  $\text{NO}_2$  and/or  $\text{NO}_3\text{-N}$  =  $\mu\text{g}$   $\text{NO}_3\text{-N}$  found  $\times$  diln factor/g sample.

Diln factors for exts: 7.045(a), 11.1; (b), 22.2; (c), 200.

### Pepsin Digestibility of Animal Protein Feeds (76) Official Final Action

## 7.048

**Principle**

Defatted sample is digested 16 hr with warm soln of pepsin under const agitation. Insol. residue is isolated by filtering, washed, dried, and weighed to det. % residue. Residue is examined microscopically and analyzed for protein. Filtration method is applicable to all animal proteins. Methods are not applicable to vegetable proteins or mixed feeds because of presence of complex carbohydrates and other compds not digested by pepsin.

## 7.049

**Apparatus**

(a) *Agitator.*—See Fig. 7.02. Continuous, slow speed (15 rpm), end-over-end type, to operate inside incubator at  $45 \pm 2^\circ$  and carry 8 oz screw-cap prescription bottles, or equiv. Agitator and bottles available from D. E. Sims, 716 Forrest Ave, Quincy, IL 62301. Stirring or reciprocating (shaking) type agitator cannot be used because solid particles collect on sides of bottle and do not contact pepsin soln. If heat from agitator motor raises incubator temp. to  $> 45^\circ$ , mount motor outside incubator by drilling hole thru side of incubator and connecting motor to

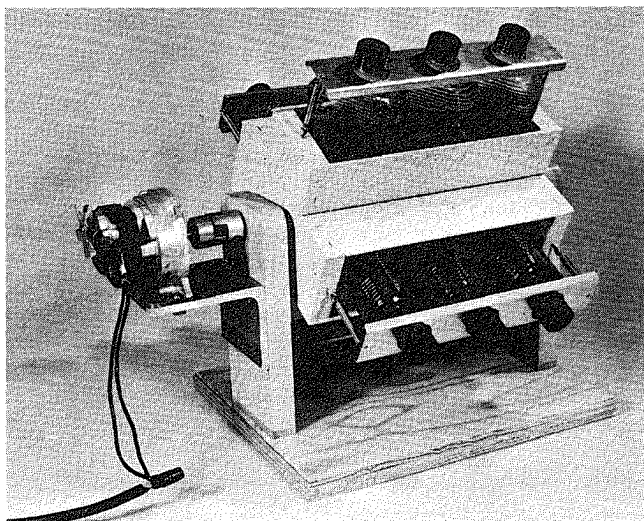

FIG. 7.02—Agitator

agitator with extension shaft and coupling (available from agitator supplier). (*Caution: See 51.012.*)

(b) *Settling rack*.—Wood or metal to hold digestion bottles at 45° angle. May be made from 2 boards nailed horizontally into "V" cut into vertical end pieces. Also available from agitator supplier, (a).

(c) *Filtering device*.—Modified California buchner, 7.063(d), available from Labconco Corp., 8811 Prospect Ave, Kansas City, MO 64132, No. 55100. (If edge of screen is rough, smooth with small-tip soldering iron.) Use with retainer sleeve, 2 × 2.75" od stainless steel tube, available from agitator supplier, (a).

(d) *Glass fiber filter*.—7 cm, Reeve Angel No. 934-AH, or equiv.

(e) *Moisture dishes*.—Al, 78 mm od × 20 mm, with outside cover and vertical sides (Curtin Matheson Scientific, Inc., No. 19370-30, or equiv.).

#### 7.050

#### Reagent

*Pepsin soln*.—0.2% pepsin (activity 1:10,000) in 0.075N HCl; do not use pepsin of activity other than 1:10,000. *Prep. just before use* by dilg 6.1 mL HCl to 1 L and heating to 42–45°. Add pepsin and stir gently until dissolved. Do not heat pepsin soln on hot plate or overheat.

#### 7.051

#### Preparation of Sample

Sieve sample, 7.001, thru No. 20 sieve. Grind portion retained on sieve to pass No. 20 sieve. Combine both portions and blend by stirring and shaking in pt (500 mL) jar. Thoro blending is essential. Because of high fat content of many animal products, grinding without sieving may cause sticking in mill, loss of moisture or fat, or poorly blended sample.

#### 7.052

#### Extraction

(*Caution: See 51.011, 51.039, and 51.054.*)

Prep. extn thimble from 11 cm Whatman No. 2 paper, or equiv., as follows: Fold paper in half; straighten paper and refold at right angles to first fold; turn paper over and repeat process with folds at 45° to original fold; while holding creased paper in one hand, place short test tube (6–8 mm smaller in diam. than extractor sample holder or cup in which thimble is to be used) at its center; fold along natural crease lines to form

4-pointed star around tube; and wrap points in same direction around tube to complete thimble.

Weigh 1.000 g ground sample (0.500 g of poultry byproducts or hydrolyzed feathers because of gummy nature and amt of residue) into thimble and ext 1 hr with ether at condensation rate of 3–4 drops/sec. (If Soxhlet is used, top of thimble should extend above siphon tube to avoid loss of solid particles. If paper contg sample is totally submerged in siphon cup, sample must be completely wrapped in paper.) Observe ether ext to det. that no solid particles were carried into solv. For approx. fat content detn, evap. ether, and dry and weigh residue. Remove paper from sample container or cup and let dry at room temp. Unfold, and quant. brush defatted sample into digestion bottle, avoiding contamination by brush bristles or filter paper fibers. Use of powder funnel is helpful to avoid loss.

#### 7.053

#### Pepsin Digestion

To defatted sample in agitator bottle add 150 mL freshly prep'd pepsin soln prewarmed to 42–45°. Be sure sample is completely wetted by pepsin soln. Stopper bottle, clamp in agitator, and incubate with const agitation 16 hr at 45°.

#### 7.054

#### Treatment of Residue

Dry individual sheets of glass fiber filter, (d), 30 min at 110° in moisture dishes with cover open. Cool in desiccator 30 min with cover closed, and weigh ( $W_1$ ).

Remove bottles from agitator. Place in 45° angle settling rack and loosen caps. Let residue settle ≥15 min. Place weighed filter in California buchner, (c), apply suction, and moisten with H<sub>2</sub>O. Place retainer sleeve on filter and press down gently. Rinse particles of residue on cap onto filter with small amt H<sub>2</sub>O. Carry bottle from rack to filter at same angle as settled and slowly pour contents thru filter as continuous small stream, avoiding all unnecessary agitation. Liq. passes thru paper as rapidly as poured, with residue spreading over surface of filter but not covering it completely until all or practically all of liq. has passed thru. If filtration rate becomes slow, it may be accelerated by adding acetone washes described below, but only if no significant amt of digestion mixt. remains on funnel when acetone is added. (Filtration (passage of aq. mixt. thru filter) should be complete within 1 min with most proteins.) After supernate has passed thru filter, quant. transfer residue onto filter as follows:

Add 15 mL acetone to bottle. Hold thumb over bottle neck and shake vigorously. Release pressure, replace thumb over bottle neck, and shake bottle in inverted position over filter. Remove thumb, letting acetone and residue discharge onto filter. Repeat rinse with second 15 mL portion acetone, shaking and releasing pressure as above. Inspect bottle, and rinse further with acetone, using policeman, if necessary. If >3 mm liq. remains on paper when acetone washes are started, it may be necessary to use three 15 mL acetone washes instead of 2 to increase filtration rate.

After all liq. passes thru funnel, wash residue and inside surface of retainer sleeve with 2 small portions acetone from wash bottle or hypodermic syringe, and suck dry. Remove retainer sleeve from funnel. Transfer filter to original moisture dish. Scrape or brush any residue particles or filter clinging to retainer sleeve or funnel onto filter in moisture dish. Dry in oven, cool, and weigh as before ( $W_2$ ). Calc. % indigestible residue =  $(W_2 - W_1) \times 100/\text{g sample}$ .

Det. indigestible protein by transferring filter contg residue directly to Kjeldahl flask. Proceed as in 7.015. (*Caution: Violent reaction may take place when NaOH is mixed with dild digestion mixt., caused by large excess H<sub>2</sub>SO<sub>4</sub> due to small amt org. material from residue and none from glass filter. Avoid by*

thoroly mixing and cooling digestion mixt. before addn of NaOH or by using 20 mL  $\text{H}_2\text{SO}_4$  in Kjeldahl digestion instead of 25 mL.) Make blank detn on 1 sheet of glass filter and subtract from each sample detn, if necessary. Calc. % protein based on original sample wt. Result represents % indigestible protein in *sample*. Convert to % crude protein content of sample not digested, "protein indigestible" = % indigestible protein in sample  $\times$  100/% total crude protein in sample.

### OTHER CONSTITUENTS

#### Crude Fat or Ether Extract

Use method 7.056 or 7.057 for mixed feeds other than (1) entirely baked and/or expanded, (2) entirely dried milk products, or (3) contg urea.

#### Direct Method—Official Final Action

##### 7.055

##### Reagent

*Anhydrous ether*.—Wash com. ether with 2 or 3 portions  $\text{H}_2\text{O}$ , add solid NaOH or KOH, and let stand until most of  $\text{H}_2\text{O}$  is abstracted from the ether. Decant into dry bottle, add small pieces of carefully cleaned metallic Na, and let stand until H evolution ceases. Keep ether, thus dehydrated, over metallic Na in loosely stoppered bottles. (Caution: See 51.034 and 51.054.)

##### 7.056

##### Determination

(Large amts  $\text{H}_2\text{O}$ -sol. components such as carbohydrates, urea, lactic acid, glycerol, and others may interfere with extn of fat; if present, ext 2 g sample on small paper in funnel with five 20 mL portions  $\text{H}_2\text{O}$  prior to drying for ether extn. Caution: See 51.009, 51.011, and 51.054.)

Ext ca 2 g sample, dried as in 7.003 or 7.006★, with anhyd. ether. Use thimble with porosity permitting rapid passage of ether. Extn period may vary from 4 hr at condensation rate of 5–6 drops/sec to 16 hr at 2–3 drops/sec. Dry ext 30 min at 100°, cool, and weigh.

#### 7.057 Indirect Method—Official Final Action

Det. moisture as in 7.003 or 7.006★; then ext dried substance as in 7.056, and dry again. Report loss in wt as ether ext.

#### 7.058 In Baked or Expanded and Intermediate Moisture (Semimoist or Soft-Moist) Pet Foods (17) Official Final Action

(To be used only on products which have been baked and/or expanded, and on intermediate moisture pet foods. Not applicable to canned, fresh, or frozen pet food. Such products should be dried at 70–110°, then ground, and drying completed by 7.003 or 7.006★ followed by 7.056 or 7.057. Caution: See 51.011, 51.054, and 51.073.)

Place ca 2 g, accurately weighed, ground, well mixed sample in Mojonnier fat-extn tube, add 2 mL alcohol to prevent lumping on addn of acid, and shake to moisten all particles. Add 10 mL HCl (25+11), mix well, and set tube 30–40 min in  $\text{H}_2\text{O}$  bath at 70–80°, shaking frequently. Cool to room temp. and add alcohol until liq. level rises into constricted portion of Mojonnier tube.

Add 25 mL ether, stopper with glass, Neoprene, or good quality rubber stopper thoroly cleaned with alcohol, and shake vigorously 1 min. Carefully release pressure so that no solv. is lost. Wash adhering solv. and fat from stopper back into extn tube with few mL redistd pet ether (bp <60°). Add 25 mL redistd pet ether, stopper, and shake vigorously 1 min. Let stand until upper liq. is practically clear or centrf. 20 min at ca 600 rpm. Pour as much of ether-fat soln as possible thru filter consisting of cotton pledget packed just firmly enough in funnel stem to let ether pass freely into 150 mL beaker contg several glass

beads. Rinse lip of tube with few mL pet ether. Re-ext liq. remaining in tube twice, each time with only 15 mL of each ether, shaking 1 min after addn of each ether. Pour clear ether soln thru filter into same beaker as before, and wash tip of tube, stopper, funnel, and end of funnel stem with few mL of mixt. of 2 ethers (1+1). Evap. slowly on steam bath under gentle stream of air or N. Continue heating on steam bath 15 min after solv. has evapd; then cool to room temp.

Redissolve dried fat residue in four 10 mL portions Et ether, filtering each portion thru small pledget of cotton into 100 mL beaker, contg few glass beads, that has been predried 30 min at 100°, cooled to room temp. in desiccator, and weighed immediately. Use fifth 10 mL portion ether for rinsing cotton and funnel. Evap. ether on steam bath, dry 90 min at 100°, cool to room temp. in desiccator, and weigh immediately. Correct this wt by blank detn on reagents used.

#### 7.059 In Dried Milk Products (18)—Official Final Action

Proceed as in 16.199(b) and 16.200, using 8.5 mL  $\text{H}_2\text{O}$  and 1.5 mL  $\text{NH}_4\text{OH}$ .

#### 7.060 In Fish Meal

See 18.046 and 18.047–18.049.

### Crude Fiber (19)—Official Final Action

#### AOCS-AOAC Method

(Caution: See 51.086.)

##### 7.061

##### Principle

Crude fiber is loss on ignition of dried residue remaining after digestion of sample with 1.25%  $\text{H}_2\text{SO}_4$  and 1.25% NaOH solns under specific conditions. Method is applicable to grains, meals, flours, feeds, and fiber-bearing material from which fat can be extd to leave workable residue.

##### 7.062

##### Reagents

(a) *Sulfuric acid soln.*—0.255 $\pm$ 0.005N. 1.25 g  $\text{H}_2\text{SO}_4$ /100 mL. Conc'n must be checked by titrn.

(b) *Sodium hydroxide soln.*—0.313 $\pm$ 0.005N. 1.25 g NaOH/100 mL, free, or nearly so, from  $\text{Na}_2\text{CO}_3$ . Conc'n must be checked by titrn.

(c) *Prepared asbestos.*—Spread thin layer acid-washed, medium or long fiber asbestos in evapg dish and heat 16 hr at 600° in furnace. Boil 30 min with 1.25%  $\text{H}_2\text{SO}_4$ , filter, wash thoroly with  $\text{H}_2\text{O}$ , and boil 30 min with 1.25% NaOH. Filter, wash once with 1.25%  $\text{H}_2\text{SO}_4$ , wash thoroly with  $\text{H}_2\text{O}$ , dry, and ignite 2 hr at 600°.

Det. blank by treating 1.0 g prepd asbestos with acid and alkali as in detn. Correct crude fiber results for any blank, which should be negligible (ca 1 mg). Asbestos recovered from detn may be used in subsequent detns.

(d) *Alcohol.*—95% or reagent alcohol, MeOH, or isopropanol.

(e) *Antifoam.*—Dow Corning Corp. Antifoam A compd dild 1+4 with mineral spirits or pet ether, or  $\text{H}_2\text{O}$ -dild Antifoam B Emulsion (1+4). Do not use Antifoam Spray.

(f) *Bumping chips or granules.*—Broken Alundum crucibles or equiv. granules (RR Alundum 90 mesh, Norton Co., 1 New Bond St, Worcester, MA 01606) are satisfactory.

##### 7.063

##### Apparatus

(a) *Digestion apparatus.*—With condenser to fit 600 mL beaker, and hot plate adjustable to temp. that will bring 200 mL

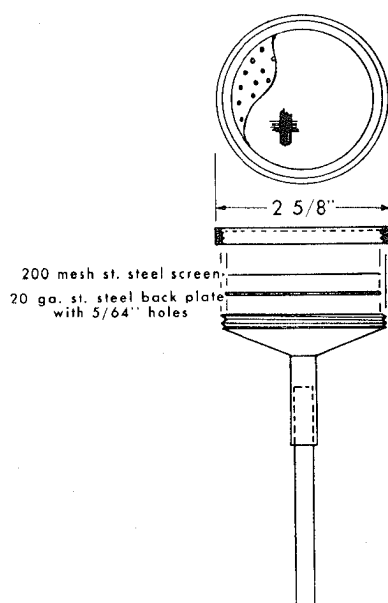

FIG. 7:03—Oklahoma State filter screen

H<sub>2</sub>O at 25° to rolling boil in 15±2 min. (Available from Labconco Corp., 8811 Prospect Ave, Kansas City, MO 64132.)

(b) *Ashing dishes*.—Silica, Vitreosil 70 × 15 mm; or porcelain, Coors, No. 450, size 1, or equiv.

(c) *Desiccator*.—With efficient desiccant such as 4–8 mesh Drierite (CaCl<sub>2</sub> is not satisfactory).

(d) *Filtering device*.—With No. 200 type 304 or 316 stainless steel screen (W. S. Tyler Co., 8200 Tyler Blvd, Mentor, OH 44060), easily washed free of digested residue. Either Oklahoma State filter screen (see Fig. 7:03; available from Labconco Corp.) or modified California plastic buchner (see Fig. 7:04; consists of 2 piece polypropylene plastic funnel manufactured by Nalge Co., 75 Panorama Creek Drive, Rochester, NY 14602, Cat. No. 4280, 70 mm (without No. 200 screen), or equiv. (also available from Labconco Corp.). Seal screen to filtering surface of funnel, using small-tip soldering iron).

(e) *Suction filter*.—To accommodate filtering devices. Attach suction flask to trap in line with aspirator or other source of vac. with valve to break vac.

(f) *Liquid preheater*.—For preheating H<sub>2</sub>O, 1.25% H<sub>2</sub>SO<sub>4</sub>, and 1.25% NaOH solns to bp of H<sub>2</sub>O. Convenient system, shown in Fig. 7:05, consists of sheet Cu tank with 3 coils of 3/8" (10 mm) od Cu tubing, 12.5' (3.8 m) long. Solder inlets and outlets where tubing passes thru tank walls. Connect to reflux condenser and fill with H<sub>2</sub>O. Keep H<sub>2</sub>O boiling with two 750 watt thermostatically controlled hot plates. Use Tygon for inlet leads to reservoirs of H<sub>2</sub>O, acid, and alkali; use gum rubber tubing for outlets. Capacity of preheater is adequate for 60 analyses in 8 hr.

#### 7.064

#### Preparation of Sample

Reduce sample (riffle is suitable) to 100 g and place portion in sealed container for H<sub>2</sub>O detn. Immediately det. H<sub>2</sub>O. Grind remainder to uniform fineness. (Weber mill (Sargent-Welch Scientific Co. S-60870) with screen 0.033–0.040" (No. 18 or 20), Micro mill (Pulverizing Machinery, Div. Mikropul Corp., 10 Chatham Rd, Summit, NJ 07901) with screen 1/25–1/16" (No. 18–No. 12), and Wiley mill with 1 mm (No. 18) screen give comparable fineness.) Since most materials lose moisture during grinding, det. H<sub>2</sub>O on ground sample at same time sample is taken for crude fiber detn.

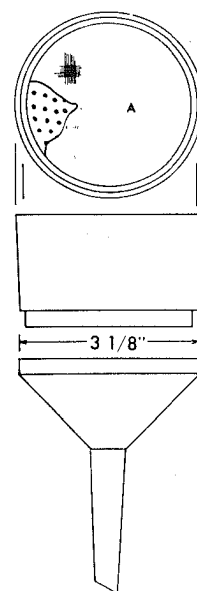

FIG. 7:04—Modified California State buchner funnel, 2-piece polypropylene plastic, covered with 200-mesh screen, A, heat-sealed to edge of filtering surface

#### 7.065

#### Determination

Ext 2 g ground material with ether or pet ether, 14.088. If fat is <1%, extn may be omitted. Transfer to 600 mL beaker, avoiding fiber contamination from paper or brush. Add ca 1 g prepd asbestos, 200 mL boiling 1.25% H<sub>2</sub>SO<sub>4</sub>, and 1 drop dild antifoam. (Excess antifoam may give high results; use only if necessary to control foaming.) Bumping chips or granules may also be added. Place beaker on digestion app. with preadjusted hot plate and boil exactly 30 min, rotating beaker periodically to keep solids from adhering to sides. Remove beaker, and filter as in (a) or (b).

(a) *Using Oklahoma filter screen*.—Turn on suction and insert screen (precoated with asbestos if extremely fine materials are analyzed) into beaker, keeping face of screen just under surface of liq. until all liq. is removed. Without breaking suction or raising filter, add 50–75 mL boiling H<sub>2</sub>O. After wash is removed,

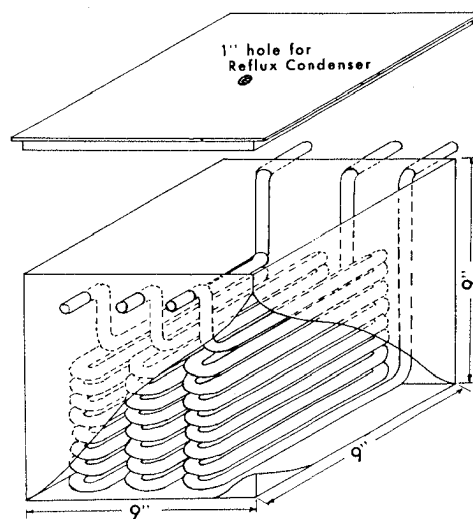

FIG. 7:05—Continuous heater for distilled water, 1.25% alkali, and 1.25% acid

repeat with three 50 mL washings. (Work rapidly to keep mat from becoming dry.) Remove filter from beaker and drain all H<sub>2</sub>O from line by raising above trap level. Return mat and residue to beaker by breaking suction and blowing back. Add 200 mL boiling 1.25% NaOH and boil exactly 30 min. Remove beaker, and filter as above. Without breaking suction, wash with 25 mL boiling 1.25% H<sub>2</sub>SO<sub>4</sub> and three 50 mL portions boiling H<sub>2</sub>O. Drain free of excess H<sub>2</sub>O by raising filter. Lower filter into beaker and wash with 25 mL alcohol. Drain line, break suction, and remove mat by blowing back thru filter screen into ashing dish. Proceed as in (c).

(b) *Using California buchner*.—Filter contents of beaker thru buchner (precoated with asbestos if extremely fine materials are being analyzed), rinse beaker with 50–75 mL boiling H<sub>2</sub>O, and wash thru buchner. Repeat with three 50 mL portions H<sub>2</sub>O, and suck dry. Remove mat and residue by snapping bottom of buchner against top while covering stem with thumb or forefinger and replace in beaker. Add 200 mL boiling 1.25% NaOH and boil exactly 30 min. Remove beaker, and filter as above. Wash with 25 mL boiling 1.25% H<sub>2</sub>SO<sub>4</sub>, three 50 mL portions H<sub>2</sub>O, and 25 mL alcohol. Remove mat and residue; transfer to ashing dish.

(c) *Treatment of residue*.—Dry mat and residue 2 hr at 130±2°. Cool in desiccator and weigh. Ignite 30 min at 600±15°. Cool in desiccator and reweigh.

% Crude fiber in ground sample =  $C = (\text{Loss in wt on ignition} - \text{loss in wt of asbestos blank}) \times 100/\text{wt sample}$ .

% Crude fiber on desired moisture basis =  $C \times (100 - \% \text{ moisture desired}) / (100 - \% \text{ moisture in ground sample})$ .

Report results to 0.1%.

#### Asbestos-Free (AF) Method (20) Official Final Action

##### 7.066

##### Principle

Principle is same as in 7.061, except sample is exposed to min. vac. needed to regulate filtration, and heating of sample solns prevents gelling or pptn of possible satd solns.

##### 7.067

##### Apparatus and Reagents

See reagents 7.062(a), (b), and (f); app. 7.063(a), (c), (d), and (f), and 14.088; and in addn:

(a) *Filtration apparatus*.—System to permit application of min. vac. necessary for filtration and washing of each sample within 3–5 min. Each unit consists of reservoir manifold connected to (1) H<sub>2</sub>O aspirator thru 120° stopcock, (2) atm. thru second stopcock with metering device, and (3) receptacle contg cone-shaped hard rubber gasket which provides vac. seal with crucible. Vac. gage attached to manifold indicates vac. applied to crucible. Crucible can be heated before and during filtration by flow of hot H<sub>2</sub>O in surrounding jacket. (For photograph of app., see JAOAC 56, 1353(1973). Filtration unit is available as Model 150 from Analytical BioChemistry Laboratories, Inc., PO Box 1097, Columbia, MO 65201.)

(b) *Crucible*.—Fritted glass, 50 mL, coarse porosity. Clean as follows: Brush, and flow hot tap H<sub>2</sub>O into crucible to remove as much ash as possible. Submerge crucible in base soln, (c)(2), ≥5 min, remove, and rinse with hot tap H<sub>2</sub>O. Submerge in HCl (1+1), (c)(1), ≥5 min, remove, and rinse thoroly with hot tap H<sub>2</sub>O followed by distd H<sub>2</sub>O. After 3–4 uses, back wash by inverting crucible on hard rubber gasket in filtration app., and flowing near-boiling H<sub>2</sub>O thru crucible under partial vac.

(c) *Cleaning solns*.—(1) *Acid soln*.—HCl (1+1). (2) *Base soln*.—Dissolve 5 g Na<sub>2</sub>H<sub>2</sub>EDTA, 50 g Na<sub>2</sub>HPO<sub>4</sub> (tech. grade), and 200 g KOH in H<sub>2</sub>O, and dil. to 1 L. Storage in sep. wide mouth

containers holding 2–3 L soln into which crucibles can be placed is convenient.

##### 7.068

##### Determination

(Caution: See 51.011 and 51.073.)

Ext 2 g ground material with ether or pet ether, 14.088. If fat is <1%, extn may be omitted. Transfer to 600 mL reflux beaker, avoiding fiber contamination from paper or brush. Add 0.25–0.5 g bumping granules, followed by 200 mL near-boiling 1.25% H<sub>2</sub>SO<sub>4</sub> soln in small stream directly on sample to aid in complete wetting of sample. Place beakers on digestion app. at 5 min intervals and boil exactly 30 min, rotating beakers periodically to keep solids from adhering to sides. Near end of refluxing place California buchner, 7.063(d), previously fitted with No. 9 rubber stopper to provide vac. seal, into filtration app., and adjust vac. to ca 25 mm Hg (735 mm pressure). At end of refluxing, flow near-boiling H<sub>2</sub>O thru funnel to warm it; then decant liq. thru funnel, washing solids into funnel with min. of near-boiling H<sub>2</sub>O. Filter to dryness, using 25 mm vac., and wash residue with four 40–50 mL portions near-boiling H<sub>2</sub>O, filtering after each washing. Do not add wash to funnel under vac.; lift funnel from app. when adding wash.

Wash residue from funnel into reflux beaker with near-boiling 1.25% NaOH soln. Place beakers on reflux app. at 5 min intervals and reflux 30 min. Near end of refluxing, turn on filtration app., place crucible, (b), in app., and adjust vac. to ca 25 mm. Flow near-boiling H<sub>2</sub>O thru crucible to warm it. (Keep near-boiling H<sub>2</sub>O flowing thru jacket during filtration and washing.) At end of refluxing, decant liq. thru crucible and wash solids into crucible with min. of near-boiling H<sub>2</sub>O. Increase vac. as needed to maintain filtration rate. Wash residue once with 25–30 mL near-boiling 1.25% H<sub>2</sub>SO<sub>4</sub> soln, and then with two 25–30 mL portions near-boiling H<sub>2</sub>O, filtering after each washing. (Filtering and washing takes ca 3–5 min/sample.) Do not add wash to crucible under vac.

Dry crucible with residue 2 hr at 130±2° or overnight at 110°, cool in desiccator, and weigh. Ash 2 hr at 550±10°, cool in desiccator, and weigh. Do not remove crucibles from furnace until temp. is ≤250°, as fritted disk may be damaged if cooled too rapidly.

% Crude fiber = Loss in wt on ignition × 100/wt sample.

#### Acid-Detergent Fiber and Lignin (21) Official Final Action

(Caution: See 51.086.)

##### 7.069

##### Reagents

(a) *Sulfuric acid*.—72% by wt. Stdze reagent grade H<sub>2</sub>SO<sub>4</sub> to sp gr 1.634 at 20° or 24.00N: Add 1200 g H<sub>2</sub>SO<sub>4</sub> to 440 mL H<sub>2</sub>O in 1 L MCA vol. flask with cooling. Stdze to 1634 g/L at 20° by removing soln and adding H<sub>2</sub>O or H<sub>2</sub>SO<sub>4</sub> as required. (Caution: See 51.030.)

(b) *Acid-detergent soln*.—Add 20 g cetyl trimethylammonium bromide (tech. grade) to 1 L 1.00N H<sub>2</sub>SO<sub>4</sub>, previously stdzd. Agitate to aid soln.

(c) *Asbestos*.—Place 100 g asbestos in 3 L flask contg 850 mL H<sub>2</sub>O. Add 1.4 L H<sub>2</sub>SO<sub>4</sub> (tech. grade), mix, and let cool 2 hr at room temp. Filter on large buchner and wash with H<sub>2</sub>O. Resuspend mat in H<sub>2</sub>O and pour into bag sewn from rectangle of fiberglass window screening, 14 × 18 mesh (bag should be ≥45 cm wide × 30 cm deep). Wash by immersion and agitation in partly filled sink to remove fine particles. Ash recovered asbestos 16 hr in 800° furnace. Store in dry form until use. Used asbestos may be rewashed, reashed, and reused. Com. prepd acid-washed asbestos is unsatisfactory unless treated with 72% H<sub>2</sub>SO<sub>4</sub> and ashed at 800°.

**7.070****Apparatus**

(a) *Refluxing apparatus*.—Any conventional app. suitable for crude fiber detns. Berzelius beakers (600 mL) and condensers made from 500 mL r-b flasks are also satisfactory.

(b) *Fritted glass crucibles*.—Use coarse porosity, 40–50 mL Pyrex crucible. Wash new crucibles and ash at 500°. Remove while still hot and place in 100° forced-draft oven  $\geq 1$  hr. Cool 15 min in desiccator over  $P_2O_5$  or  $Mg(ClO_4)_2$  and weigh in same order samples are to be weighed. Check balance 0 after each weighing if crucibles are still warm. Hold length of time from oven to balance pan as const as possible and always weigh crucibles in same order.

**7.071****Determination of Acid-Detergent Fiber**

Weigh 1 g air-dried sample ground to pass 1 mm screen, or approx. equiv. amt wet material, into refluxing container. Add 100 mL acid-detergent soln at room temp.

Heat to boiling in 5–10 min; reduce heat to avoid foaming as boiling begins. Reflux 60 min from onset of boiling, adjusting boiling to slow, even level. Remove container, swirl, and filter thru weighed ( $W_1$ ) fritted glass crucible, using min. suction. Increase vac. only as needed. Shut off vac. Break up filtered mat with rod and fill crucible  $\frac{2}{3}$  full with hot (90–100°)  $H_2O$ . Stir and let soak 15–30 sec. Dry with vac. and repeat  $H_2O$  washing, rinsing sides of crucible. Wash twice similarly with acetone.

Repeat acetone washings until no more color is removed, breaking up all lumps so that solv. wets all particles of fiber. Remove residual acetone with vac. Dry 3 hr or overnight in 100° forced-draft oven and weigh ( $W_2$ ). Calc. % acid-detergent fiber =  $100 (W_2 - W_1)/S$ , where  $S$  = g sample  $\times$  g oven-dried matter/g air-dried or wet matter, detd on sep. sample.

**7.072****Determination of Lignin**

To crucible contg fiber, **7.071**, add 1 g asbestos. Place crucible in 50 mL beaker for support or arrange crucibles in shallow enamel pan. Cover contents of crucible with cooled (15°) 72%  $H_2SO_4$  and stir with glass rod to smooth paste, breaking all lumps. Fill crucible about half-way with acid and stir. Leave glass rod in crucible; refill with 72%  $H_2SO_4$  and stir hourly as acid drains, keeping crucible at 20–23° (cool if necessary). After 3 hr, filter as completely as possible with vac., and wash with hot  $H_2O$  until acid-free to pH paper. Rinse sides of crucible and remove stirring rod. Dry crucible in 100° forced-draft oven, cool in desiccator over  $P_2O_5$  or  $Mg(ClO_4)_2$ , and weigh ( $W_3$ ). Ignite crucible in 500° furnace 2 hr or until C-free. Place crucible while still hot into 100° forced-draft oven 1 hr. Transfer to desiccator, cool, and weigh ( $W_4$ ).

Det. asbestos blank by weighing 1 g asbestos into tared crucible. Proceed as above, beginning "Cover contents of crucible . . ." Record any loss in wt on ashing ( $W_5$ ). Discontinue detn of blank if asbestos blank is  $< 0.0020$  g/g asbestos. Calc. % acid-insol. lignin =  $(W_3 - W_4 - W_5)/S$ .

**Total Sugars (22)—Official Final Action****7.073****Reagents**

(a) *Soxhlet modification of Fehling soln*.—Prep. as in **31.034(a)** and (b).

(b) *Invert sugar std soln*.—1.0%. Prep. as in **31.034(c)**, but do not neutze. Dil. to 0.5% just before use for analysis of most products.

(c) *Lactose std soln*.—1.0%. Dissolve 5.000 g lactose in  $H_2O$  and dil. to 500 mL. Prep. daily.

**7.074****Apparatus**

(a) *Lamp*.—Fluorescent desk lamp or 150 watt reflector spot lamp, to illuminate boiling soln.

(b) *Heater*.—Glas-Col mantle, 250 mL, placed over mag. stirrer. Adjust heat so that 50 mL  $H_2O$  contg stirring bar will boil in 3 min. Mag. stirring hot plate is also satisfactory.

**7.075****Preparation of Sample and Inversion**

(a) *Feeds containing molasses*.—Weigh appropriate size sample, prepd as in **7.002** but not ground, to provide final soln ca 0.5% invert sugar but  $\geq 5$  g, into 250 mL P flask (Corning Glass Works No. 5840, or equiv.). Add 150 mL  $H_2O$ , swirl to wet and mix, and heat just to bp. Let stand to cool, dil. to vol., mix, and let stand to settle coarse particles. Transfer 50 mL supernate to 100 mL vol. flask and add 2.5 mL HCl (sp gr 1.18 at 20/4°). Let stand overnight at  $\geq 25^\circ$ , dil. to vol., and mix. (If aliquot to be used in detn is  $> 25$  mL, it is necessary to neutze inverted soln.)

(b) *Feeds containing milk products*.—Weigh appropriate size sample to provide final soln ca 1% lactose into 250 mL vol. flask. Thoroughly moisten sample with  $H_2O$ , swirl to dissolve lactose, dil. to vol., mix, and let stand to settle coarse particles. Proceed as in **7.077(b)**.

**7.076****Standardization**

Fill 50 mL buret, with offset tip, with std sugar soln (invert sugar for use with **7.077(a)** and lactose with **7.077(b)**). Proceed as in **31.080**, par. 2, except use same type flask as used in **7.077**, do not add  $H_2O$ , and start stirring after addn of indicator.

**7.077****Determination**

(a) *Difference method*.—Add reagents and stirring bar to 250 mL extn flask (Corning Glass Works No. 5160, or equiv.) or to erlenmeyer, as in **7.076**. Transfer aliquot inverted soln, (a), to flask so that  $> 1$  but  $< 5$  mL std soln will be required to reach end point, place on preheated mantle or hot plate, heat to bp, boil 2 min, add ca 1 mL indicator, and begin stirring. Complete detn by titrg with std sugar soln to same end point used in stdzn. Color change is not so sharp as in stdzn, but under suitable light it is definite, discernible, and repeatable.

(b) *Alternative method*.—Fill buret with sample soln, (b), or inverted sample soln, (a). As in **7.076**, place reagents in flask, place on heater, add sample soln to within 2 mL of final titrn (detd by trial), bring to bp, boil 2 min, and complete titrn as in (a).

**7.078****Calculations**

% Total sugar (as invert or lactose)

$$= [(F - M) \times I \times 100] / [V \times (W/250) \times D],$$

where  $F$  = mL std sugar required to reduce mixed Soxhlet reagent in stdzn;  $M$  = mL std soln required to complete detn (omit in alternative method);  $I$  = concn std soln;  $V$  = mL sample soln in aliquot used;  $W$  = g sample; and  $D$  = diln factor.

Report total sugars, expressed as invert or as lactose.

**7.079 Sucrose (23)—Official Final Action**

Place 10 g sample in 250 mL vol. flask. If material is acid, neutze by adding 1–3 g  $CaCO_3$ . Add 125 mL 50% alcohol by vol., mix thoroly, and boil on steam bath or by partially immersing flask in  $H_2O$  bath 1 hr at 83–87°, using small funnel in neck of flask to condense vapor. Cool and let mixt. stand several hr, preferably overnight. Dil. to vol. with neut. 95% alcohol, mix thoroly, let settle or centr. 15 min at 1500 rpm, and decant closely. Pipet 200 mL supernate into beaker and evap. on steam

bath to 20–30 mL. Do not evap. to dryness. Little alcohol in residue does no harm.

Transfer to 100 mL vol. flask and rinse beaker thoroly with H<sub>2</sub>O, adding rinsings to flask. Add enough *satd neut. Pb(OAc)<sub>2</sub> soln* (ca 2 mL) to produce flocculent ppt, shake thoroly, and let stand 15 min. Dil. to vol. with H<sub>2</sub>O, mix thoroly, and filter thru dry paper. Add enough anhyd. Na<sub>2</sub>CO<sub>3</sub> or K oxalate to filtrate to ppt all Pb, again filter thru dry paper, and test filtrate with little anhyd. Na<sub>2</sub>CO<sub>3</sub> or K oxalate to make sure that all Pb has been removed.

Place 50 mL prepd soln in 100 mL vol. flask, add piece of litmus paper, neutze with HCl, add 5 mL HCl, and let inversion proceed at room temp. as in 31.026(c). When inversion is complete, transfer soln to beaker, neutze with Na<sub>2</sub>CO<sub>3</sub>, return soln to 100 mL flask, dil. to vol. with H<sub>2</sub>O, filter if necessary, and det. reducing sugars in 50 mL soln (representing 2 g sample) as in 31.038. Calc. results as invert sugar.

% Sucrose = [% total sugar after inversion – % reducing sugars before inversion (both calcd as invert sugar)] × 0.95.

Because insol. material of grain or cattle food occupies some space in flask as originally made up, correct by multiplying all results by factor 0.97, as results of large number of detns on various materials show av. vol. of 10 g material to be 7.5 mL.

#### Minerals in Feeds by Atomic Absorption Spectrophotometry (29)—Official Final Action

(Caution: See 51.006.)

##### 7.091

##### Apparatus

Atomic absorption spectrophotometer.—See 2.109.

##### 7.092

##### Operating Parameters

See Table 2:04, except use fuel-rich air-C<sub>2</sub>H<sub>2</sub> flame for Ca and Mg, and ranges of operation for μg element/mL soln are: Ca 5–20, Cu 2–20, Fe 5–20, Mg 0.5–2.5, Mn 5–20, and Zn 1–5.

##### 7.093

##### Reagents

(See introduction to 2.110. Com. prepd std solns may be used.)

(a) *Calcium std solns*.—Prep. as in 2.110(a).

(b) *Copper, iron, magnesium, manganese, and zinc std solns*.—Prep. stock solns as in 2.110(b), (c), (e), (f), and (g), and dil. aliquots with 0.1–0.5N HCl to make ≥4 std solns of each element within range of detn.

##### 7.094

##### Preparation of Sample Solution

(a) *Dry ashing (not applicable to mineral-mix feeds)*.—Ash 2–10 g sample in well-glazed porcelain dish. Start in cold furnace, bring to 550°, and hold 4 hr. Cool, add 10 mL 3N HCl, cover with watch glass, and boil gently 10 min. Cool, filter into 100 mL vol. flask, and dil. to vol. with H<sub>2</sub>O. Subsequent dilns with 0.1–0.5N HCl may be necessary to bring sample solns into anal. range, except for Ca. Final Ca diln must contain enough La soln, 2.110(d), to provide 1% La concn after diln to vol. with H<sub>2</sub>O.

(b) *Wet digestion*.—Proceed as in 7.097(a), adding 25 mL HNO<sub>3</sub> for each 2.5 g sample and dilg to 100 mL with H<sub>2</sub>O. Digestion can be made at low heat on hot plate, using 600 mL beaker covered with watch glass. Subsequent dilns with 0.1–0.5N HCl may be necessary to bring sample solns into anal. range, as in (a).

##### 7.095

##### Determination and Calculation

See 2.112–2.113.

#### Calcium—Official Final Action

##### 7.096 Method I (30)

(Applicable to mineral feeds only)

Weigh 2 g finely ground sample into SiO<sub>2</sub> or porcelain dish and ignite in furnace to C-free ash, but avoid fusing. Boil residue in 40 mL HCl (1+3) and few drops HNO<sub>3</sub>. Transfer to 250 mL vol. flask, cool, dil. to vol., and mix thoroly. Pipet 25 mL clear liq. into beaker, dil. to ca 100 mL, and add 2 drops Me red, 2.055(i). Add NH<sub>4</sub>OH (1+1) dropwise to pH 5.6, as shown by intermediate brownish-orange. If overstepped, add HCl (1+3) with dropper to orange. Add 2 more drops HCl (1+3). Color should now be pink (pH 2.5–3.0), not orange. Dil. to ca 150 mL, bring to boil, and slowly add, with const stirring, 10 mL hot satd (4.2%) soln of (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub>. If red changes to orange or yellow, add HCl (1+3) dropwise until color again changes to pink. Let stand overnight for ppt to settle. Filter supernate thru quant. paper, gooch, or fritted glass filter (fine Pyrex is preferable), and wash ppt thoroly with NH<sub>4</sub>OH (1+50). Place paper or crucible with ppt in original beaker, and add mixt. of 125 mL H<sub>2</sub>O and 5 mL H<sub>2</sub>SO<sub>4</sub>.

Heat to  $\geq 70^\circ$  and titr. with 0.1*N*  $\text{KMnO}_4$ , **50.025–50.026**, to first slight pink. Presence of paper may cause color to fade in few sec. Correct for blank and calc. % Ca.

### Method II (31)

7.097

#### Preparation of Solution

(Caution: See **51.026** and **51.028**.)

(a) Weigh 2.5 g sample into 500 or 800 mL Kjeldahl flask. Add 20–30 mL  $\text{HNO}_3$  and boil gently 30–45 min to oxidize all easily oxidizable matter. Cool soln somewhat and add 10 mL 70–72%  $\text{HClO}_4$ . Boil very gently, adjusting flame as necessary, until soln is colorless or nearly so and dense white fumes appear. Use particular care not to boil to dryness (Danger!) at any time. Cool slightly, add 50 mL  $\text{H}_2\text{O}$ , and boil to drive out any remaining  $\text{NO}_2$  fumes. Cool, dil., filter into 250 mL vol. flask, dil. to vol., and mix thoroly.

(b) Weigh 2.5 g finely ground sample into  $\text{SiO}_2$  or porcelain dish and ignite as in **7.009**. Add 40 mL  $\text{HCl}$  (1+3) and few drops  $\text{HNO}_3$  to residue, boil, transfer to 250 mL vol. flask, cool, dil. to vol., and mix thoroly.

7.098

#### Determination

Pipet suitable aliquot of clear soln, **7.097(a)** or **(b)**, into beaker, dil. to 100 mL, and add 2 drops Me red, **2.055(i)**. Continue as in **7.096**, beginning "Add  $\text{NH}_4\text{OH}$  (1+1) dropwise . . ." except use 0.05*N*  $\text{KMnO}_4$  for titrn.

(100 mL is suitable aliquot of sample soln for grain feeds; for mineral feeds, 25 mL aliquot may be taken and titrd with 0.1*N*  $\text{KMnO}_4$ . For suitable precision, size of sample, aliquot, and concn of  $\text{KMnO}_4$  must be so adjusted that  $\geq 20$  mL std  $\text{KMnO}_4$  soln is used.)

### Soluble Chlorine

#### Titration Method (32)—Official Final Action

7.099

#### Reagents

(a) *Potassium chloride std soln.*—0.001 g Cl/mL. Recrystallize reagent KCl 3 times from  $\text{H}_2\text{O}$ , dry at  $110^\circ$ , and heat at ca  $500^\circ$  to const wt. Dissolve 2.1028 g in  $\text{H}_2\text{O}$  and dil. to 1 L.

(b) *Silver nitrate soln.*—Dissolve 5 g  $\text{AgNO}_3$  in 1 L  $\text{H}_2\text{O}$  and adjust soln so that 1 mL = 1 mL std KCl soln.

(c) *Potassium thiocyanate soln.*—Dissolve 2.5 g KSCN in 1 L  $\text{H}_2\text{O}$  and adjust so that 1 mL = 1 mL std  $\text{AgNO}_3$  soln. Stdze as in **50.004**.

(d) *Ferric sulfate soln.*—Dissolve 60 g  $\text{Fe}_2(\text{SO}_4)_3 \cdot \text{Aq.}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(e) *Ferric sulfate indicator.*—To filtered 25% soln of  $\text{Fe}_2(\text{SO}_4)_3 \cdot \text{Aq.}$  add equal vol.  $\text{HNO}_3$ .

7.100

#### Determination

Transfer 3 g sample to 300 mL erlenmeyer. Add 50 mL  $\text{Fe}_2(\text{SO}_4)_3$  soln (accurately measured), swirling flask to prevent caking of sample and to facilitate soln of Cl. Add 100 mL (also accurately measured)  $\text{NH}_4\text{OH}$  (1+19). Swirl flask just enough to ensure soln of Cl and thoro mixing of soln. (Very little swirling is necessary. If soln is agitated by vigorous vertical shaking, filtration will be difficult.) Let mixt. settle 10 min. Filter thru dry 11 cm Whatman No. 41 paper, or equiv. Use 50 mL aliquots ( $\frac{1}{3}$  of total) on samples low in Cl (0–2% Cl) and 25 mL aliquots ( $\frac{1}{6}$  of total) on samples high in Cl ( $>2\%$ ). For mineral and other feeds contg  $\geq 10\%$  Cl, weigh 1 g and use 15 mL ( $\frac{1}{10}$  of total).

If approx. % Cl in sample is not known, take 10 mL aliquot for trial titrn. To this add 10 mL  $\text{HNO}_3$  and 10 mL  $\text{Fe}_2(\text{SO}_4)_3$  indicator. Dil. to ca 50 mL. Add 0.5 mL KSCN soln and immediately add,

with stirring, enough  $\text{AgNO}_3$  soln to entirely eliminate any reddish color. From this titrn calc. vol.  $\text{AgNO}_3$  soln necessary to ppt all Cl in aliquot to be used, adding excess equal to ca 10% total vol. necessary, altho somewhat greater excess will not affect results. Use min. total of 10 mL.

To sample aliquot in 250 mL beaker add 10 mL  $\text{HNO}_3$  and 10 mL  $\text{Fe}_2(\text{SO}_4)_3$  indicator (or 20 mL soln contg equal vols of these solns). Add, with stirring, calcd vol.  $\text{AgNO}_3$  soln. Heat to boiling and cool to room temp., stirring enough to coagulate ppt. (Cooling may be hastened by immersion of beakers in cold  $\text{H}_2\text{O}$ .) Titr. excess  $\text{AgNO}_3$  with KSCN. End point is indicated by first appearance of reddish tint that persists 15 sec. For accurate work, use ref. soln contg all ingredients except KSCN. End point is first change in color.

### Potentiometric Method (33)

#### Official Final Action

7.101

#### Apparatus

*Potentiometer.*—With Ag-AgCl reference electrode and Ag-indicating electrode (Fisher Scientific Co. No. 9–313–216 and 13–639–122, or equiv.).

7.102

#### Standardization

Weigh 125 mg dry NaCl into 400 mL beaker. Add 200 mL  $\text{H}_2\text{O}$  and 1 mL  $\text{HNO}_3$ .

Null potentiometer and titr. NaCl soln with 0.1*N*  $\text{AgNO}_3$  soln. Plot mL  $\text{AgNO}_3$  soln against mv or scale readings. Add titrant in small enough increments so that voltage end point is obvious. Use same end point for samples.

7.103

#### Determination

(a) *Samples containing less than 5% sodium chloride.*—Weigh 5.844 g sample into 400 mL beaker. Add ca 200 mL  $\text{H}_2\text{O}$  and 1 mL  $\text{HNO}_3$ . Swirl mixt. gently and let stand 10 min for complete soln of chlorides. Titr., while stirring, to same voltage end point as in stdzn.

$$\% \text{ NaCl} = \text{mL } 0.1\text{N } \text{AgNO}_3 / 10.$$

(b) *Samples containing more than 5% sodium chloride.*—Weigh 5.844 g sample into 200 mL vol. flask. Add ca 190 mL  $\text{H}_2\text{O}$  and 1 mL  $\text{HNO}_3$ , dil. to vol. with  $\text{H}_2\text{O}$ , mix, and let stand 10 min. Transfer aliquot contg equiv. of ca 125 mg NaCl to 400 mL beaker, dil. to ca 200 mL, add 1 mL  $\text{HNO}_3$ , and titr. as in (a).

$$\% \text{ NaCl} = \text{diln factor} \times \text{mL } 0.1\text{N } \text{AgNO}_3 / 10.$$

### Cobalt (34)—Official Final Action

7.104

#### Reagents

(a) *Cobalt std soln.*—0.05 mg Co/mL. Dissolve 0.2385 g  $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$  (do not dry; use as received) in  $\text{H}_2\text{O}$  and dil. to 1 L. Dil., if necessary, to suitable concn to prep. std curve.

(b) *Nitroso-R salt soln.*—Dissolve 1 g  $\text{C}_{10}\text{H}_4\text{OH} \cdot \text{NO}(\text{SO}_3\text{Na})_2$  in  $\text{H}_2\text{O}$  and dil. to 500 mL.

(c) *Spekker acid.*—Mix 150 mL 85%  $\text{H}_3\text{PO}_4$  and 150 mL  $\text{H}_2\text{SO}_4$ , and dil. to 1 L with  $\text{H}_2\text{O}$ .

(d) *Sodium acetate soln.*—Dissolve 500 g  $\text{NaOAc} \cdot 3\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 1 L with  $\text{H}_2\text{O}$ .

7.105

#### Preparation of Standard Curve

To 1, 2, etc., up to 11 mL portions std Co soln in 100 mL vol. flasks add 2 mL Spekker acid, 10 mL nitroso-R salt soln, and 10 mL  $\text{NaOAc}$  soln. Prep. blank by using 2 mL Spekker acid and 10 mL  $\text{NaOAc}$  soln, but omitting nitroso-R salt soln. Bring solns to bp on hot plate. Add 5 mL  $\text{HNO}_3$  and boil  $\geq 1$ , but  $\leq 2$  min. Cool, and dil. to 100 mL.

## 7.106

## Determination

(Caution: See 51.026 and 51.059.)

Ash 2 g sample 2 hr at 600°, transfer to 200 mL vol. flask with 20 mL HCl and 50 mL H<sub>2</sub>O, boil 5 min, cool, and dil. to vol. Let soln settle. Pipet suitable aliquot into small flask. For samples contg 0.01–0.2% Co use equiv. of 0.25 g sample. Adjust amt to ≤0.5 mg Co. Soln no longer appears to follow Beer's law above this amt.

Pass brisk current of H<sub>2</sub>S thru soln 10 min. Filter directly into 100 mL vol. flask thru Whatman No. 40 paper. Wash with ca 50 mL 1% H<sub>2</sub>SO<sub>4</sub> satd with H<sub>2</sub>S. Add 2 small glass beads and boil off H<sub>2</sub>S. (Flasks must be given individual attention, as violent bumping may occur.) Shake flasks often. Add 5 mL HNO<sub>3</sub> and boil until nitrous fumes no longer appear. (Take care, as vol. of soln will be low and bumping and spattering may occur. At first indication of this, remove immediately from hot plate.) Small amt HNO<sub>3</sub> remaining will not affect result. Cool, add 2 drops phthln, and adjust to first faint pink with ca 30% NaOH soln. Immediately add 2 mL Spektr acid followed by 10 mL nitroso-R salt soln and 10 mL NaOAc soln. Bring to vigorous boil, carefully add 5 mL HNO<sub>3</sub>, and boil ≥1 but ≤2 min. Cool, and dil. to vol.

Compare color with std Co solns in photoelec. colorimeter, using green or No. 54 filter, or in spectrophtr at 540 nm. Read color within 2 hr. Report % Co to third decimal place.

## Copper (35)—Official Final Action

## 7.107

## Preparation of Standard Curve

Dissolve 1.9645 g CuSO<sub>4</sub>·5H<sub>2</sub>O in H<sub>2</sub>O and dil. to 500 mL. (1 mL = 1 mg Cu.) Use from 1 to 10 mL of this soln to prep. set of stds in 100 mL Pyrex g-s vol. flasks. Add 4 mL HCl, dil. to 50 mL, add 5 mL tetraethylenepentamine, dil. to vol. with H<sub>2</sub>O, stopper, and mix thoroly. Prep. blank, using all reagents except Cu. Filter blank and stds before reading color as in 7.108.

## 7.108

## Determination

Prep. sample soln as in 7.106, using 8 g sample. Pipet 50 mL aliquot into 100 mL Pyrex g-s vol. flask, add 5 mL tetraethylenepentamine, dil. to vol. with H<sub>2</sub>O, and mix thoroly. Filter, and compare colors within 30 min in photoelec. colorimeter (red or No. 66 filter) or read in spectrophtr at 620 nm. Report % Cu to third decimal place.

## Fluorine—Official Final Action

## 7.109

## Colorimetric Method

See 25.049–25.055, especially 25.053.

## Ion Selective Electrode Method (36)

## 7.110

## Apparatus

(a) *Electrodes*.—Fluoride ion selective electrode (Model 94-09, Orion Research Inc., or equiv.) and single junction calomel ref. electrode, plastic sleeve-type (Model 90-01, Orion Research Inc., or equiv.).

(b) *Magnetic stirrer*.—With 4 cm (1½") Teflon-coated stirring bar. Use mat to insulate sample from motor heat.

(c) *pH meter*.—Corning digital Model 112 (Corning Scientific Instruments, Medfield, MA 02052, or equiv.).

## 7.111

## Reagents

(Deionized H<sub>2</sub>O may be used.)

(a) *Sodium acetate soln*.—3*M*. Dissolve 408 g NaOAc·3H<sub>2</sub>O with H<sub>2</sub>O in 1 L vol. flask. When soln warms to room temp., dil. to vol. with H<sub>2</sub>O. Adjust to pH 7.0 with few drops HOAc.

(b) *Sodium citrate soln*.—1.32*M*. Dissolve 222 g Na citrate·2H<sub>2</sub>O with ca 250 mL H<sub>2</sub>O in 1 L vol. flask. Add 28 mL HClO<sub>4</sub>, dil. to vol., and mix.

(c) *Fluoride std solns*.—(1) *Stock soln*.—500 ppm. Accurately weigh 1.105 g NaF (reagent grade, dried 4 hr at 100°) into 1 L vol. flask. Dissolve and dil. to vol. with H<sub>2</sub>O, and mix. Store in plastic bottle. (2) *Intermediate soln I*.—100 ppm. Pipet 20 mL stock soln into 100 mL vol. flask, dil. to vol. with H<sub>2</sub>O, and mix. (3) *Intermediate soln II*.—10 ppm. Pipet 2 mL stock soln into 100 mL vol. flask, dil. to vol. with H<sub>2</sub>O, and mix. (4) *Working solns*.—Pipet 3, 5, and 10 mL intermediate soln II and 5 and 10 mL intermediate soln I into five 100 mL vol. flasks to prep. 0.3, 0.5, 1.0, 5.0, and 10 ppm F working solns, resp. To each add 10.0 mL 1*N* HCl, 25.0 mL NaOAc·3H<sub>2</sub>O soln, (a), and 25.0 mL Na citrate soln, (b). Dil. to vol. with H<sub>2</sub>O and mix.

## 7.112

## Preparation of Sample

Accurately weigh well mixed sample contg ca 400 µg F into 200 mL vol. flask. Pipet in 20 mL 1*N* HCl and stir 20 min at high speed on mag. stirrer. Add 50.0 mL NaOAc soln, (a), and 50.0 mL Na citrate soln, (b), to dissolved sample. Dil. to vol. with H<sub>2</sub>O and mix.

## 7.113

## Determination

Connect F and ref. electrodes to pH meter, place electrodes in low concn F soln, and warm up pH meter. Pour 50–70 mL std and corresponding sample solns into sep. 100 mL beakers. Place electrodes in each soln and while stirring with mag. stirrer at const rate, read mv of std and unknown solns. Rinse and blot off electrodes and stirring bar between solns. Construct std curve on 3 cycle semilogarithmic paper. Read ppm F of sample soln from std curve.

$$\% F = \text{ppm F} \times \text{mL sample soln} \times 10^{-6} \times 100/\text{g sample}$$

## Iodine in Mineral Mixed Feeds—Official Final Action

## 7.114 ★ Knapheide-Lamb Method (37) ★

See 22.084–22.086, 10th ed.

## 7.115 Elmslie-Caldwell Method (38)

(Not applicable to iodized mineral feeds contg little or no org. matter. Caution: See 51.047.)

Place sample contg 3–4 mg I in 200–300 mL Ni dish. Add ca 5 g Na<sub>2</sub>CO<sub>3</sub>, 5 mL NaOH soln (1+1), and 10 mL alcohol, taking care that entire sample is moist. Dry at ca 100° to prevent spattering upon subsequent heating (30 min is usually enough).

Place dish and contents in furnace heated to 500° and keep at that temp. 15 min. (Ignition of sample at 500° appears to be necessary only to carbonize any sol. org. matter that would be oxidized by Br-H<sub>2</sub>O if not so treated. Temp. >500° may be used if necessary.) Cool, add 25 mL H<sub>2</sub>O, cover dish with watch glass, and boil gently 10 min. Filter thru 18 cm paper and wash with boiling H<sub>2</sub>O, catching filtrate and washings in 600 mL beaker (soln should total ca 300 mL). Neutze to Me orange with 85% H<sub>3</sub>PO<sub>4</sub> and add 1 mL excess.

★ Surplus method—see inside front cover.

Add excess Br-H<sub>2</sub>O and boil soln gently until colorless, and then 5 min longer. Add few crystals *salicylic acid* and cool soln to ca 20°. Add 1 mL 85% H<sub>3</sub>PO<sub>4</sub> and ca 0.5 g KI, and titr. I with 0.005N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, adding starch soln when liberated I color is nearly gone. 1 mL 0.005N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 0.1058 mg I.

#### Acid-Soluble Manganese (39) Official Final Action

## 7.116

## Reagent

*Potassium permanganate std soln.*—500 ppm Mn. Prep. and stdze as in 50.025–50.026, except use 1.4383 g KMnO<sub>4</sub> and 0.12 g Na oxalate. Transfer aliquot contg 20 mg Mn to beaker. Add 100 mL H<sub>2</sub>O, 15 mL H<sub>3</sub>PO<sub>4</sub>, and 0.3 g KIO<sub>4</sub>, and heat to bp. Cool, and dil. to 1 L. Protect from light. Dil. this soln contg 20 ppm Mn with H<sub>2</sub>O (previously boiled with 0.3 g KIO<sub>4</sub>/L) to make convenient working stds in range of concns to be compared.

## 7.117

## Determination

(Caution: See 51.026 and 51.030.)

Ash weighed sample, 5–15 g, at dull red heat (ca 600°) in porcelain dish. Cool, and add 5 mL H<sub>2</sub>SO<sub>4</sub> and 5 mL HNO<sub>3</sub> to ash in dish or to ash transferred to beaker with 20–30 mL H<sub>2</sub>O. Evap. to white fumes. If C is not completely destroyed, add addnl portions HNO<sub>3</sub>, boiling after each addn. Cool slightly, transfer to 50 or 100 mL vol. flask, and add vol. dil. H<sub>3</sub>PO<sub>4</sub> soln (8+92) equal to ½ vol. of flask (25 or 50 mL). Cool, dil. to vol., mix, and filter or let stand until clear.

If 50 mL flask was used, pipet 25 mL clear soln into beaker or 50 or 100 mL vol. flask and add 15 mL H<sub>2</sub>O. If 100 mL flask was used, pipet 50 mL into beaker or 100 mL flask and add 30 mL H<sub>2</sub>O. Heat nearly to bp, and with stirring or swirling add 0.3 g KIO<sub>4</sub> for each 15 mg Mn present. Keep 30–60 min at 90–100°, or until color development is complete. Cool, dil. to measured vol. of 50 or 100 mL, and mix. Compare with std KMnO<sub>4</sub> soln in photoelec. colorimeter or in spectrophtr at 530 nm. Calc. ppm Mn.

## Phosphorus

#### Alkalimetric Ammonium Molybdophosphate Method (40)—Official Final Action

## 7.118

## Reagents

(a) *Molybdate soln.*—Dissolve 100 g MoO<sub>3</sub> in mixt. of 144 mL NH<sub>4</sub>OH and 271 mL H<sub>2</sub>O. Cool, and slowly pour soln, stirring constantly, into cool mixt. of 489 mL HNO<sub>3</sub> and 1148 mL H<sub>2</sub>O. Keep final mixt. in warm place several days or until portion heated to 40° deposits no yellow ppt. Decant soln from any sediment and keep in g-s vessels.

(b) *Acidified molybdate soln.*—To 100 mL molybdate soln, (a), add 5 mL HNO<sub>3</sub>. Filter immediately before use.

(c) *Sodium hydroxide std soln.*—Dil. 324.03 mL 1N alkali, carbonate-free, 50.032–50.036, to 1 L. (100 mL of this soln should neutze 32.40 mL 1N acid; 1 mL = 1 mg or 1% P<sub>2</sub>O<sub>5</sub> on basis of 0.1 g sample.) (Since burets in const use may become so corroded as to increase their capacity, test them at least annually.)

(d) *Std acid soln.*—Prep. soln of HCl or of HNO<sub>3</sub>, corresponding to concn of (c) or to ½ this concn, and stdze by titrn against (c), using phthln.

## 7.119

## Determination

Prep. sample soln as in 7.097(a). Pipet, into beaker or flask, aliquot corresponding to 0.4 g sample for P<sub>2</sub>O<sub>5</sub> content of sample

<5%; 0.2 g for 5–20%; 0.1 g for >20%. Add 5–10 mL HNO<sub>3</sub>, depending on method of soln (or equiv. in NH<sub>4</sub>NO<sub>3</sub>); then add NH<sub>4</sub>OH until ppt that forms dissolves only slowly on vigorous stirring, dil. to 75–100 mL, and adjust to 25–30°. If sample does not give ppt with NH<sub>4</sub>OH as test of neutzn, make soln slightly alk. to litmus paper with NH<sub>4</sub>OH and then slightly acid with HNO<sub>3</sub> (1+3). Add 20–25 mL acidified molybdate soln for P<sub>2</sub>O<sub>5</sub> content <5%; 30–35 mL for 5–20%; and enough acidified molybdate soln to ensure complete pptn for >20%. Shake or stir mech. 30 min at room temp.; decant *at once* thru filter and wash ppt twice by decanting with 25–30 mL portions H<sub>2</sub>O, agitating thoroly and allowing to settle. Transfer ppt to filter and wash with cold H<sub>2</sub>O until filtrate from 2 fillings of filter yields pink color on adding phthln and 1 drop of the std alkali. Transfer ppt and filter to beaker or pptg vessel, dissolve ppt in small excess of the std alkali, add few drops of phthln, and titr. with std acid. Report as % P.

#### Photometric Method (41)—Official Final Action

## 7.120

## Apparatus

*Spectrophotometer.*—Capable of isolating 400 nm band and accepting ≤15 mm diam. cells.

## 7.121

## Reagents

(a) *Molybdovanadate reagent.*—Prep. as in 2.022(a), except add only 250 mL 70% HClO<sub>4</sub> to NH<sub>4</sub>VO<sub>3</sub> soln.

(b) *Phosphorus std solns.*—(1) *Stock soln.*—2 mg P/mL. Dissolve 8.788 g KH<sub>2</sub>PO<sub>4</sub> in H<sub>2</sub>O and dil. to 1 L. (2) *Working soln.*—0.1 mg P/mL. Dil. 50 mL stock soln to 1 L.

## 7.122

## Preparation of Standard Curve

Transfer aliquots of working std soln contg 0.5, 0.8, 1.0, and 1.5 mg P to 100 mL vol. flasks. Treat as in 7.123, beginning "Add 20 mL molybdovanadate reagent, . . ." Prep. std curve by plotting mg P against %T on semilog paper.

## 7.123

## Determination

Ash 2 g sample, in 150 mL beaker, 4 hr at 600°. Cool, add 40 mL HCl (1+3) and several drops HNO<sub>3</sub>, and bring to bp. Cool, transfer to 200 mL vol. flask, and dil. to vol. with H<sub>2</sub>O. Filter, and place aliquot contg 0.5–1.5 mg P in 100 mL vol. flask. Add 20 mL molybdovanadate reagent, dil. to vol. with H<sub>2</sub>O, and mix well. Let stand 10 min; then read %T at 400 nm against 0.5 mg std set at 100% T. (Use ≤15 mm diam. cells.) Det. mg P from std curve.

% P = mg P in aliquot/(g sample in aliquot × 10).

#### Basic Feed Microscopy (42)—Official Final Action

## 7.124

## Apparatus

(a) *Magnifier-fluorescent illuminator with desk base, 3×, or reading glass.*

(b) *Microscopes and illuminator.*—See 44.002(n) and (q). Following are preferred:

(1) *Widefield stereoscopic microscope.*—With arm rests, flat stage (remove spring holders), optional substage illumination, inclined eyepiece, and lenses to magnify ca 7–30×, 15× optimum.

(2) *Compound microscope.*—With mech. stage, substage condenser, inclined binocular eyepiece, 3 position rotating nose-piece, lenses to magnify ca 36–400×, 120× optimum.

(3) *Microscope illuminator*.—With iris diaphragm; movable stand holder with rod to permit adjusting light source as to ht and angle for substage or direct over-stage lighting; able to hold 2 blue glass filters or 1 blue and 1 ground glass; 60–100 watt bulb.

(c) *Sieves*.—Nest of 5" No. 10, 20, 40, 60, 80, and bottom pan.

(d) *Stages*.—Dark Co glass plates 4 × 4" (Fisher Scientific Co. No. 13-735); or blue paper and microscope slides.

(e) *Spot plates*.—Black and white.

(f) *Forceps*.—Fine pointed, curved. If necessary, bend and grind on emery wheel for good contact of points.

(g) *Dropping bottles*.—Amber, 30 mL, as reagent dispensers.

(h) *Micro-spatula; micro-stirring rods made by drawing out glass rods; spoon*.

## 7.125

### Reagents

(a) *Chloroform*.—Tech. Recover by filtration and distn.

(b) *Acetone*.—Tech.

(c) *Acetone, dilute*.—Dil. 75 mL acetone with 25 mL H<sub>2</sub>O.

(d) *Dilute hydrochloric acid*.—Dil. 1 vol. HCl with 1 vol. H<sub>2</sub>O.

(e) *Dilute sulfuric acid*.—Dil. 1 vol. H<sub>2</sub>SO<sub>4</sub> with 1 vol. H<sub>2</sub>O.

(f) *Iodine soln*.—Dissolve 0.75 g KI and 0.1 g I in 30 mL H<sub>2</sub>O and add 0.5 mL HCl. Store in amber dropping bottle.

(g) *Millon reagent*.—Dissolve, by gently warming, 1 part by wt Hg in 2 parts by wt HNO<sub>3</sub>. Dil. with 2 vols H<sub>2</sub>O. Let mixt. stand overnight and decant supernate. Soln contains Hg(NO<sub>3</sub>)<sub>2</sub>, HgNO<sub>3</sub>, HNO<sub>3</sub>, and some HNO<sub>2</sub>. Store in g-s bottle. (*Caution: See 51.079.*)

(h) *Molybdate soln*.—Add 100 mL 10% NH<sub>4</sub>NO<sub>3</sub> soln to 400 mL molybdate soln, 7.118(a). Use only clear supernate to fill 30 mL amber dropping bottle. Discard and refill when crystn occurs.

(i) *Mountant I*.—Dissolve 10 g chloral hydrate in 10 mL H<sub>2</sub>O and add 10 mL glycerol. Store in amber dropping bottle.

(j) *Mountant II*.—Dissolve 160 g chloral hydrate in 100 mL H<sub>2</sub>O and add 10 mL HCl.

(k) *Silver nitrate soln*.—10%. Dissolve 10 g AgNO<sub>3</sub> in 100 mL H<sub>2</sub>O.

## 7.126

### Standards

(a) *Feed ingredients*.—Collect ingredients used in grain and stock feeds known to conform to definitions of Association of American Feed Control Officials as stds. Store in 4 oz bottles. To control insects, add ca 1 mL CS<sub>2</sub>, and stopper. Become thoroly familiar with structural appearance of stds before and after treatment with org. solvs.

(b) *Weed seeds*.—Collect common weed seeds occurring in grains. Most may be found in foreign material obtained after sieving com. whole grains with U.S. Grain Testing Sieve having  $\frac{5}{64}$ " (2.5 mm) triangular holes. Identify from illustration in "Identification of Crop and Weed Seeds" (USDA Handbook 219 (1963), Government Printing Office, Washington, DC 20402). Store in numbered vials. Become familiar with those weed seeds designated as prohibited and restricted noxious under state laws of individual concern. (See "State Noxious-Weed Seed Requirements Recognized in the Administration of the Federal Seed Act" (USDA, Agricultural Marketing Service, Grain Div., Hyattsville, MD 20782).)

### Identification of Vegetable Tissues

## 7.127

### Principle

Feeds are fractionated according to particle size and cleared where necessary for clear observation; conglomerates are disintegrated into constituents and fractions arranged on stage suitable for microscopic examination at lowest magnification

that permits identification of components when compared to std feed ingredients.

## 7.128

### General Methods

(a) *Scratch feeds*.—Spread representative portion of sample on white paper and examine under magnifier-fluorescent illuminator at 3× or with reading glass. Identify grains and weed seeds; note other foreign material, heat- and insect-damaged particles, live insects, and rodent excreta; examine for smut, ergot, and mold ("Grain Inspection Manual," USDA).

(b) *Mashes comparatively free from adhering fine particles*.—

(1) *Low power microscopy*.—Arrange in nest form 3 sieves that will adequately fractionate feed according to particle size. Generally, for cattle feeds use No. 10, 20, and 40; for poultry feeds, No. 20, 40, and 60. Include bottom pan. Add ca 10 g unground feed (plastic tablespoon makes convenient scoop) to nest, and sieve thoroly. With spatula, spread portion from each sieve on 4 × 4" Co glass stage and place under stereoscopic microscope. (Blue paper may also be used as stage.) Arrange illuminator above and near stage so light strikes sample at angle of ca 45° for shadow contrast. Adjust magnification (ca 15× optimum), illumination, and light filters to individual preference for clear observation. Blue light or northern daylight is preferred. Examine each fraction on stage sep. and systematically. Observe feed particles, continually probing, turning, and testing resistance to pressure with forceps. Note particle size, shape, color, resistance to pressure, texture, odor, and major structural features. Compare with stds. If desired, transfer individual particles with forceps to second glass plate for direct comparison with corresponding tissues from stds. Likewise transfer and break up conglomerates by gentle pressure with flat end of forceps. Make list of observed ingredients. Neglect trace grains which may be normal impurities in major grains. (Consult "Official Grain Standards of the United States," USDA, for amts of "other grains" permissible as impurities in whole grains.)

(2) *High power microscopy*.—Lower illuminator and select filters so adequate blue light is reflected thru substage condenser of high power microscope. With microspatula, transfer little of fine sievings from bottom sieve and pan to slide, add 2 drops mountant I, stir, and disperse with microstirring rod. Examine microscopically (120× optimum). Compare histologically with stds. Remove slide, add 1 drop I soln, stir, and re-examine. Starch cells are stained pale blue to black; yeasts and other protein cells, pale yellow to brown. If further tissue clarification is desired, boil little of same fine sievings 1 min with ca 5 mL mountant II. Cool, transfer drop or 2 of bottom settlings to slide, cover, and examine microscopically.

(c) *Oily feeds or those containing large particles obscured by adhering fine particles*.—(Most poultry feeds and unknowns are best examined by this technic.) Place ca 10 g unground feed in 100 mL tall-form beaker and nearly fill with CHCl<sub>3</sub> (hood). Stir briefly and let settle ca 1 min. With spoon, transfer floating (org.) material to 3.5" (9 cm) cover glass, drain, and dry on steam bath. Sieve, and proceed as in (b). If desired, filter, dry, suspend fine particles in CHCl<sub>3</sub>, and examine microscopically (rarely necessary).

(d) *Feeds in which molasses has caused lumpiness and otherwise obscured vision*.—Place ca 10 g unground feed in 100 mL tall-form beaker. Add 75 mL 75% acetone, stir few min to dissolve molasses, and let settle. Carefully decant and repeat extn. Wash residue twice with acetone by decantation, dry on steam bath, sieve, and proceed as in (b).

(e) *Pellets or crumbles*.—Gently grind few pellets at time in mortar with pestle with enough pressure to sep. pellet into its constituents, but not to break up constituents themselves. Sieve first grind thru No. 20 sieve and return particles remaining on

sieve to mortar for further grinding. Depending on nature of pellet, proceed with ground material as in (b), (c), or (d).

#### **Identification of Animal Tissues and Major Mineral Constituents**

##### **7.129**

##### **Principle**

Feeds contg animal tissues and minerals when suspended in  $\text{CHCl}_3$  readily sep. into 2 fractions: (1) Org. fraction which floats, consisting of muscle fibers, connective tissue, dried ground organs, feather remains, hoof and horn particles, etc. from either animal or marine products, plus all vegetable tissues. (2) Mineral fraction which sinks, consisting of bones, fish scales, teeth, and minerals.

##### **7.130**

##### **Preparation of Sample**

Perform  $\text{CHCl}_3$  flotation sepn as in 7.128(c). Collect floating material and dry on steam bath. Decant  $\text{CHCl}_3$ , collect mineral fraction, and dry on steam bath.

##### **7.131**

##### **Identification of Animal Tissue**

Examine dried floating material as in 7.128(b).

##### **7.132**

##### **Identification of Major Mineral Constituents**

Place dried mineral fraction on nest of No. 40, 60, and 80 sieves and bottom pan. Sieve and place the 4 fractions in sep. groups on same Co glass plate or blue paper stage. Examine under stereoscopic microscope at ca 15 $\times$ . Animal and fish bones, fish scales, and mollusc shells are generally recognizable. Salt usually occurs in cubes which may be dyed. Calcite form of limestone occurs as rhombohedrons.

##### **7.133**

##### **Confirmatory Tests**

With forceps, place unknown particle on glass plate and break up by applying gentle pressure with flat surface. Working under stereoscopic microscope, sep. particles ca 2.5 cm and place beside each a fractional drop of reagent solns listed by touching end of dropper to plate. Push particle into liq. with microstirring rod and observe what occurs at interface. Follow order given until pos. identification is obtained. If preferred, perform tests in black spot plate.

(a) *Silver nitrate soln.*—(1) Crystal immediately turns chalk white and slowly expands: chloride, probably salt. (2) Crystal turns yellow and yellow needles begin to grow: mono- or dibasic phosphate, generally dicalcium phosphate. (3) Sparingly sol. white needles form ( $\text{Ag}_2\text{SO}_4$ ): sulfate, Mn-MgSO<sub>4</sub>. (4) Particles slowly darken: bone.

(b) *Dilute hydrochloric acid.*—(1) Vigorous effervescence:  $\text{CaCO}_3$ . (2) Mild effervescence or none: make following tests.

(c) *Molybdate soln.*—Formation of minute yellow crystals at some distance from particle: tricalcium phosphate, either bone or rock phosphate. (All phosphates react, but mono- and dibasic phosphates have been identified with  $\text{AgNO}_3$ .)

(d) *Millon reagent.*—(1) Disintegrated particles mostly float, turn pink to red (protein), and fade in ca 5 min: bone phosphate. (2) Particles appear to swell and disintegrate but remain on bottom: defluorinated rock phosphate. (3) Particles merely disintegrate slowly: rock phosphate.

(e) *Dilute sulfuric acid.*—Long, thin white needles slowly form on addn of drop of  $\text{H}_2\text{SO}_4$  (1+1) to HCl (1+1) soln of particle: confirms Ca.

##### **7.134 Identification of Furazolidone, Tylosin, and Zovalene**

See 42.001–42.004.

## **PRESERVATIVES**

### **Ethoxyquin (1,2-Dihydro-6-ethoxy-2,2,4-trimethylquinoline) (43)—Official Final Action**

##### **7.135**

##### **Reagents and Apparatus**

(a) *Quinine sulfate reference soln.*—1  $\mu\text{g}/\text{mL}$  0.1N  $\text{H}_2\text{SO}_4$ . Dissolve 0.100 g quinine sulfate USP in 1 L 0.1N  $\text{H}_2\text{SO}_4$ . Dil. 10 mL aliquot of this soln to 1 L with 0.1N  $\text{H}_2\text{SO}_4$ . Use to calibrate photofluorometer.

(b) *Ethoxyquin std solns.*—Add 100.0 mg liq. ethoxyquin to 100 mL vol. flask and dil. to vol. with pet ether (*Soln A*). Dil. 5 mL *Soln A* to 100 mL with pet ether (*Soln B*, 50  $\mu\text{g}/\text{mL}$ ). Dil. 5 mL *Soln B* to 100 mL with pet ether (*Soln C*, 2.5  $\mu\text{g}/\text{mL}$ ). Dil. 10 mL *Soln C* to 20 mL with pet ether (1.25  $\mu\text{g}/\text{mL}$ ) and 5 mL to 25 mL (0.50  $\mu\text{g}/\text{mL}$ ).

(c) *Photofluorometer.*—Equipped with primary filter passing 365 nm Hg line (Corning Glass Works No. 5874 (CS7-39), or equiv.) and secondary filter passing 420–500 nm (Corning Glass Works 3389 + 5543 + 4784, half stock thickness, or equiv.).

##### **7.136**

##### **Preparation of Standard Curve**

Adjust photofluorometer to read 0 with pet ether and 100 with quinine sulfate ref. soln. Obtain fluorescence readings for ethoxyquin std solns contg 0–2.5  $\mu\text{g}/\text{mL}$ . Plot readings against  $\mu\text{g}$  ethoxyquin/mL on linear paper.

##### **7.137**

##### **Determination**

Place 10 $\pm$ 0.1 g finely ground sample in 100 mL beaker and slurry with 50 mL MeOH. Stir and let stand 10 min. Decant thru plug of glass wool into 250 mL vol. flask. Reslurry residue with two 50 mL portions MeOH, decant, and filter, combining all filtrates. Dil. to vol. with MeOH. Transfer 25 mL aliquot to 250 mL separator, add 100 mL  $\text{H}_2\text{O}$ , and mix well. Add 50 mL pet ether, stopper, and shake moderately 1 min. Let stand few min to sep. (If emulsion forms, add ca 100 mg NaCl crystals. After emulsion breaks, drain aq. lower layer into 250 mL beaker.) Transfer pet ether layer to second 250 mL separator, return aq. layer to first separator, and re-ext with two 25 mL portions pet ether.

Add 50 mL  $\text{H}_2\text{O}$  to combined pet ether exts in separator, stopper, and shake moderately. Let sep., drain lower aq. layer, and discard. Transfer pet ether layer to 100 mL vol. flask, and dil. to vol. with pet ether. Adjust photofluorometer as above and det. fluorescence readings. Obtain  $\mu\text{g}$  ethoxyquin/mL from std curve.  $\text{Ppm ethoxyquin} = 100 \times \mu\text{g}/\text{mL}$ .

If untreated feed is available, prep. std curve from series of samples contg 0–250  $\mu\text{g}$  ethoxyquin/10 g and carried thru detn.

## 8. Baking Powders and Baking Chemicals

### 8.001 Preparation of Sample—Official Final Action

Remove entire sample from package, pass thru No. 20 sieve, and mix thoroly.

### Total Carbon Dioxide (1)—Official Final Action

(Applicable to baking powders contg added  $\text{CaCO}_3$ )

### 8.002

### Reagent

*Displacement soln.*—Dissolve 100 g  $\text{NaCl}$  or  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$  in 350 mL  $\text{H}_2\text{O}$ . Add ca 1 g  $\text{NaHCO}_3$  and 2 mL Me orange, 5.014(e), and then enough  $\text{H}_2\text{SO}_4$  (1+5) or  $\text{HCl}$  (1+2) to make just acid (decided pink). Stir until all  $\text{CO}_2$  is removed. This soln is used in gas-measuring tube and leveling bulb and seldom needs replacement.

### 8.003

### Apparatus

*Chittick apparatus.*—Fig. 8:01. Connect decomposition flask, A, by glass T-tube, B, provided with stopcock, C, to graduated gas-measuring tube, D, connected in turn with leveling bulb, E. For A always use 250 mL wide-mouth extn flask of Pyrex or

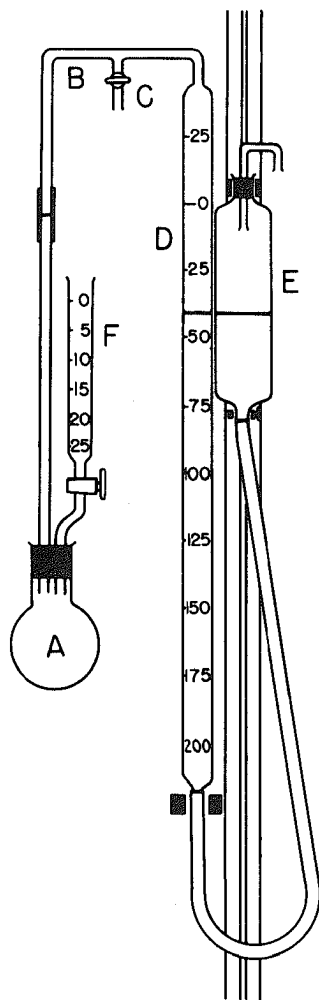

FIG. 8:01—Chittick apparatus for gasometric determination of carbon dioxide

other resistant glass fitted with 2-hole rubber stopper, thru one hole of which passes extended tip of 25 mL buret, F, and thru other, glass tube of same diam. as connecting T-tube. Use buret graduated in mL at  $20^\circ$ , numbered at 5 mL intervals, and fitted with extra-long tip bent to pass thru rubber stopper. Connect glass tube leading from decomposition flask to T-tube with rubber tubing to permit rotation of flask. Use gas-measuring tube graduated in mL at  $20^\circ$  with 0 mark at point 25 mL below top marking to allow for graduating upward from 0 to 25 mL and downward from 0 to 200 mL. Connect gas-measuring tube to ca 300 mL leveling bulb with long rubber tube.

(Available from Sargent-Welch Scientific Co.)

### 8.004

### Determination (2)

Weigh 1.7 g prepd sample, 8.001, into flask A, and connect flask with app., Fig. 8:01. Open stopcock C, and using leveling bulb E, bring displacement soln to 10 mL graduation above 0 mark. (This 10 mL is practically equal to vol. of acid to be used in decomposition.) Let app. stand 1–2 min for temp. and pressure within app. to come to room conditions.

Close stopcock, lower leveling bulb somewhat to reduce pressure within app., and slowly add 10 mL  $\text{H}_2\text{SO}_4$  (1+5) or  $\text{HCl}$  (1+2) to decomposition flask from buret F. To prevent escape of liberated  $\text{CO}_2$  thru acid buret into air, at all times during decomposition keep displacement soln at level lower in leveling bulb than that in gas-measuring tube. Rotate and then vigorously agitate flask to mix contents intimately. Let stand 5 min to secure equilibrium. Equalize pressure in measuring tube, using leveling bulb, and read vol. of gas in tube. Observe temp. of air surrounding app. and also barometric pressure, and multiply mL gas evolved by factor given in table, 52.007, for this temp. and pressure.

$$\% \text{CO}_2 \text{ by wt} = \text{corrected reading} / 10.$$

### 8.005 Residual Carbon Dioxide (3)—Official Final Action

(a) *After drying on water bath.*—Place 1.7 g baking powder in clean, dry, 250 mL wide-mouth Soxhlet extn flask, A, Fig. 8:01. Add 20 mL  $\text{H}_2\text{O}$ . Put flask on cover of  $\text{H}_2\text{O}$  bath (single or multiple) in which boiling  $\text{H}_2\text{O}$  is kept at const level of 5 cm below top of bath. ( $\text{H}_2\text{O}$  in bath must boil vigorously all thru detn. Opening in cover of bath must be 7.5 cm diam. to prevent flask from touching  $\text{H}_2\text{O}$ .) Evap. contents of flask until no moisture is visible in residue or inside surface of flask. (Sample should be completely dry in 1.5–2 hr.) Leave flask on  $\text{H}_2\text{O}$  bath 2 hr more. Add 10 mL  $\text{H}_2\text{O}$ , and let stand until flask is at room temp. (ca 1 hr).

Det.  $\text{CO}_2$  with Chittick app. as in 8.004, using correction factors in 52.007. Shake flask vigorously until further shaking produces no increase in reading.

(b) *After drying in oven.*—Place 1.7 g sample in clean, dry, 250 mL wide-mouth Soxhlet extn flask, A, Fig. 8:01. Tap flask to spread sample evenly on bottom. Add 10 mL  $\text{H}_2\text{O}$  with pipet. Stir with glass rod to break up powder that may have caked on bottom of flask. Wash down stirring rod and sides of flask with 10 mL  $\text{H}_2\text{O}$ . Place flask on shelf near center of air oven set at  $100 \pm 2^\circ$ , and evap. to dryness. After 5 hr, remove from oven, add 10 mL  $\text{H}_2\text{O}$ , and cool to same temp. as air surrounding Chittick app., 8.003. Det.  $\text{CO}_2$  in residue with Chittick app., using correction factors in 52.007. Shake flask vigorously until further shaking produces no increase in reading.

**8.006 Available Carbon Dioxide—Official Final Action**(Applicable to baking powders contg added  $\text{CaCO}_3$ )Subtract residual  $\text{CO}_2$ , **8.005**, from total  $\text{CO}_2$ , **8.004**.**Neutralizing Value—Official Final Action****8.007 Of Acid-Reacting Materials Other Than Phosphates**

Dissolve 1 g sample in hot  $\text{H}_2\text{O}$  and titr. with 0.2N NaOH, using phthln. Express result as parts  $\text{NaHCO}_3$  equiv. to 100 parts of the acid-reacting material.

**8.008 Of Monocalcium Phosphate (4)**

Weigh 0.84 g sample into 375 mL casserole. Add 24 mL cold  $\text{H}_2\text{O}$  and, after stirring for moment, add 90.0 mL 0.1N NaOH. Bring suspension to bp in exactly 2 min, and boil 1 min. While soln is still boiling hot, add 1 drop phthln, and back-titr. with 0.2N HCl until all pink disappears. Boil soln 1 min, and again add 0.2N HCl until pink just disappears.

$90 - (\text{mL } 0.2\text{N HCl} \times 2) = \text{neutrg value, parts } \text{NaHCO}_3 \text{ equiv. to 100 parts of the phosphate.}$

**8.009 Of Anhydrous Monocalcium Phosphate (4)**

Use 100 mL 0.1N NaOH and stir intermittently 5 min before bringing to bp. Proceed as in **8.008**.

**8.010 Of Sodium Acid Pyrophosphate (4)**

Weigh 0.84 g sample and 20 g NaCl into 375 mL casserole, and slowly add 25 mL  $\text{H}_2\text{O}$  while stirring. Stir and crush with flat-end rod 3–5 min. Add 90.0 mL 0.1N NaOH and 1 drop phthln, and titr. with 0.2N HCl until pink disappears. If "starch filled" or 50% neutrg strength pyrophosphate is being titrd, use 70.0 mL 0.1N NaOH.

$\text{Vol. (mL) } 0.1\text{N NaOH} - (\text{mL } 0.2\text{N HCl} \times 2) = \text{neutrg value, parts } \text{NaHCO}_3 \text{ equiv. to 100 parts Na acid pyrophosphate.}$

**Of Sodium Aluminum Phosphate (5)****AOAC-Food Chemicals Codex Method****8.011****Apparatus**

*Magnetic stirrer-hot plate.*—Must be capable of bringing assay soln to bp within 5 min. Alternatively, use ordinary hot plate and manual stirring.

**8.012****Determination**

Accurately weigh ca 0.84 g sample, transfer to 250 mL beaker, and add 20 g NaCl, 5 mL 10% Na citrate. $\cdot 2\text{H}_2\text{O}$  soln, and 25 mL  $\text{H}_2\text{O}$ . Pipet (or deliver from buret) 120 mL stdzd 0.1N NaOH, **50.032–50.034**, swirling during addn. Stir on mag. stirrer-hot plate at slow to medium speed; avoid spattering. Bring to bp in 3–5 min, and boil *exactly* 5 min. Remove from hot plate, and immediately cool to 25°. Titr. immediately with mag. stirring to pH 8.5 with stdzd 0.2N HCl, **50.011–50.012**, using pH meter previously stdzd with pH 7.0 buffer. Stir addnl 5 min and add 0.2N HCl to obtain pH 8.5.

$$\text{Neutrg value} = (V_1/N_1 - V_2/N_2) \times (0.84 \times 10)/W,$$

where  $V_1$  and  $N_1$  = vol. and normality of NaOH, resp.;  $V_2$  and  $N_2$  = vol. and normality of HCl, resp.; and  $W$  = g sample.

**8.013 Tartaric Acid, Free or Combined (Qualitative Test) (6)—Official Final Action**

(Applicable in presence of phosphates)

Shake ca 5 g sample repeatedly with ca 250 mL cold  $\text{H}_2\text{O}$  in flask, and let insol. portion settle. Decant soln thru filter, and evap. filtrate to dryness. Powder residue, add few drops 1% resorcinol soln, **31.146**, and ca 3 mL  $\text{H}_2\text{SO}_4$ , and heat slowly. Tartaric acid is indicated by rose-red, discharged on diln with  $\text{H}_2\text{O}$ .

**Cream of Tartar and Free Tartaric Acid in Tartrate Powders (7)—Official Final Action****Total, Combined, and Free Tartaric Acid****8.014****Determination**

To 2.5 g sample in 250 mL vol. flask add 100 mL  $\text{H}_2\text{O}$  at ca 50°, and hold at room temp. ca 30 min, shaking occasionally. Cool, dil. to vol. with  $\text{H}_2\text{O}$ , shake vigorously, and filter thru large fluted paper. Pipet 2 portions of 100 mL each of *clear* filtrate into 250 mL beakers, and evap. to ca 20 mL. To 1 portion add 3.5 mL ca 1N KOH. Mix well, and add 2 mL HOAc. Again mix well and add 100 mL alcohol, stirring constantly. Treat other portion similarly, but use 1N NaOH instead of KOH. Then treat each mixt. sep. as follows: Cool to ca 15°, stir vigorously ca 1 min, and leave in refrigerator overnight. Collect ppt in gooch on thin, tightly tamped pad of asbestos. Rinse beaker with ca 75 mL ice-cold 80% alcohol, carefully washing down sides of beaker. Finally wash sides of crucible with 25 mL alcohol and suck dry. Transfer contents of crucible to original beaker with ca 100 mL hot  $\text{H}_2\text{O}$ , and titr. with 0.1N alkali, using phthln. Designate titer of portion treated with KOH as "x" and that treated with NaOH as "y."

**8.015****Calculations**

$$\% \text{ Total tartaric acid} = 1.5(x + 0.6).$$

$$\% \text{ Cream of tartar} = 1.88(y + 0.6).$$

$$\% \text{ Free tartaric acid} = 1.5(x - y).$$

In above formulas "0.6" represents solubility of cream of tartar in reaction mixt. in terms of 0.1N alkali.

**Free Tartaric Acid (Direct Determination)****8.016****Reagent**

*Saturated alcohol.*—To ca 50 g finely powd pure cream of tartar in erlenmeyer add ca 100 mL alcohol and 100 mL  $\text{H}_2\text{O}$ , shake vigorously several min, and let stand 15 min, shaking occasionally. Filter on paper in buchner; wash with ca 200 mL alcohol (1+1), then with alcohol, and finally with ether. Dry at temp. of boiling  $\text{H}_2\text{O}$ . To 500 mL *absolute* alcohol add ca 5 g of the purified cream of tartar and let stand 2 hr, shaking occasionally. Properly purified cream of tartar requires  $\leq 0.15$  mL 0.1N alkali to neutze 100 mL of mixt. of 50 mL  $\text{CHCl}_3$  and 150 mL of the satd alcohol.

**8.017****Determination**

Weigh 1.25 g sample into *absolutely dry* 200 mL vol. flask, add 50 mL  $\text{CHCl}_3$ , and let stand ca 5 min, shaking occasionally. (Discard detn if upon addn of  $\text{CHCl}_3$ , powder sticks to bottom of flask, indicating moisture.) Add 100 mL satd alcohol, shake ca 5 min, and let stand 30 min, shaking at frequent intervals. (It is not necessary to filter the alcohol reagent.) Dil. to vol. with the satd alcohol, shake few min, and filter thru large fluted paper. Titr. 100 mL clear filtrate with 0.1N alkali, using phthln. Vol. (mL) alkali used  $\times 1.2 = \% \text{ free tartaric acid.}$

**8.018 Free Tartaric Acid (Qualitative Test)**

Ext 5 g sample with absolute alcohol and evap. alcohol from ext. Dissolve residue in  $\text{NH}_4\text{OH}$  (1+10), transfer to test tube, add good-size crystal of  $\text{AgNO}_3$ , and heat gently. Tartaric acid is indicated by formation of Ag mirror. (If desired, alc. ext may be tested as in 8.013.)

**Starch—Official Final Action****8.019 Direct Acid Hydrolysis Method**

(For baking powders and baking chemicals free from Ca)

Stir 5 g sample 1 hr in 250 mL beaker with 50 mL cold  $\text{H}_2\text{O}$ . Transfer to filter and wash with 250 mL cold  $\text{H}_2\text{O}$ . Heat insol. residue 2.5 hr with 200 mL  $\text{H}_2\text{O}$  and 20 mL HCl (sp gr 1.125, 52.002(c)) in flask provided with reflux condenser. Cool, and nearly neutze with NaOH. Transfer to 250 mL vol. flask, dil. to vol., filter, and det. glucose in aliquot of filtrate as in 31.038. Wt glucose obtained  $\times 0.925 = \text{wt starch}$ .

**8.020 Indirect Method (8)**

(For baking powders and baking chemicals contg Ca)

Mix 5 g sample with 200 mL HCl (1+11) in 500 mL vol. flask and let mixt. stand 1 hr, shaking frequently. Filter on 11 cm hardened paper, taking care to obtain clear filtrate. Rinse flask once without attempting to remove all starch, and wash paper twice with cold  $\text{H}_2\text{O}$ . Carefully wash starch from paper back into flask with 200 mL  $\text{H}_2\text{O}$ . Add 20 mL HCl (sp gr 1.125) and proceed as in 8.019. (Treatment with HCl, without dissolving starch, effectively removes Ca, which otherwise would be pptd as tartrate by alk. Cu soln.)

**Aluminum****Qualitative Test (9)—Official Final Action**

(In presence of phosphates)

**8.021****Reagents**

(a) *Ammonium acetate soln.*—50%. Dissolve 50 g  $\text{NH}_4\text{OAc}$  in 50 mL  $\text{H}_2\text{O}$ .

(b) *Aurintricarboxylic acid soln.*—0.1%. Dissolve 0.1 g aurintricarboxylic acid in  $\text{H}_2\text{O}$  and dil. to 100 mL.

**8.022****Detection**

Place 1 g sample in 250 mL beaker, add 5 mL ca 1*N* HCl and 20 mL  $\text{H}_2\text{O}$ , and heat until starch hydrolyzes. Add 100 mL cold  $\text{H}_2\text{O}$ , 5 mL 10%  $\text{NaNH}_2\text{HPO}_4 \cdot 4\text{H}_2\text{O}$  soln, and 3 drops Me orange. Add  $\text{NH}_4\text{OH}$  dropwise until ppt forms or color changes; then add 1*N* HCl dropwise until ppt dissolves or color changes plus 2 or 3 drops excess. Add 5 mL aurintricarboxylic acid soln and let stand 1 min. Add 50%  $\text{NH}_4\text{OAc}$  soln dropwise until ppt forms or color changes and then 1 mL excess. Let stand 5 min, stirring occasionally, and filter. Bright red ppt on filter paper indicates presence of Al.

**Atomic Absorption Spectrophotometric Method (10)—Official First Action****8.023****Apparatus**

*Atomic absorption spectrophotometer.*—Perkin-Elmer Model 303, or equiv. Typical operating parameters for this app. are given in Table 8:01. Operator must become familiar with optimum settings for his own app. and use table only as guide. (Caution: See 51.006.)

**Table 8:01 Operating Parameters**

Wavelength, nm	309.3
Slit width, mm	1
Source, ma	30
$\text{N}_2\text{O}$ , aspirating	4.5 (scale divisions)
$\text{N}_2\text{O}$ , auxiliary and aspirating	5.5 (scale divisions)
$\text{C}_2\text{H}_2$ fuel	6 (metal ball scale division)
Flame	reducing
Ht, burner to light path, in.	$\frac{1}{8}$
Sample uptake, mL/min	4
Optimum concn range, $\mu\text{g/mL}$	50–150

**8.024****Reagents**

(Do not use <2 mL pipets or <25 mL vol. flasks. Stock solns and (1+10) dilns may be stored indefinitely.)

(a) *Diluting soln.*—To 500 mL  $\text{H}_2\text{O}$  add 20 mL  $\text{H}_2\text{SO}_4$  and 2.5 g NaCl; dil. to 1 L with  $\text{H}_2\text{O}$ .

(b) *Aluminum std solns.*—(1) *Stock soln.*—1 mg Al/mL. Dissolve 1.000 g pure Al wire in min. amt HCl. Evap. almost to dryness, add 500 mL  $\text{H}_2\text{O}$ , 20 mL  $\text{H}_2\text{SO}_4$ , and 2.5 g NaCl, and dil. to 1 L with  $\text{H}_2\text{O}$ . (2) *Working solns.*—Dil. aliquots of stock soln with dilg soln, (a), to make  $\geq 4$  std solns within concn range of instrument.

**8.025****Preparation of Sample**

(Caution: See 51.019.)

Accurately weigh ca 1 g sample into 250 mL Kjeldahl flask, add 2.0 mL  $\text{H}_2\text{SO}_4$ , and then slowly add 3 mL 30%  $\text{H}_2\text{O}_2$ . When initial vigorous reaction subsides, apply heat from Bunsen flame until sample begins to char. Add addnl 1 mL increments  $\text{H}_2\text{O}_2$  and heat until soln no longer chars; finally heat to fumes of  $\text{SO}_3$ . Cool, add 50 mL  $\text{H}_2\text{O}$  and 1 Pyrex glass chip, and boil 3–5 min. Cool and filter, if necessary, thru Whatman No. 2 paper into 100 mL vol. flask, washing paper thoroly with  $\text{H}_2\text{O}$ , and dil. to vol. Prep. reagent blank of 2.0 mL  $\text{H}_2\text{SO}_4$  and same total amt 30%  $\text{H}_2\text{O}_2$  used for sample. Measure *A* directly or dil. with dilg soln, (a), within range of instrument.

**8.026****Determination**

Set up app. as in Table 8:01, or use previously established optimum settings for app. Zero app. while aspirating dilg soln, (a). Det. *A* of  $\geq 4$  std solns within anal. range, alternating with sample soln readings. Flush burner with dilg soln, (a), and check 0 point between readings. Correct for reagent blank reading if significant, and det. Al content from std curve of *A* against  $\mu\text{g Al/mL}$ :

$$\% \text{ Al} = (\mu\text{g Al/mL}) \times (F/\text{g sample}) \times 10^{-4},$$

where *F* = 100 or  $100 \times \text{mL final diln/mL aliquot}$ , if original 100 mL is dild.

**8.027 Insoluble Ash and Preparation of Solution (11) Official Final Action**

Char 5 g sample in Pt dish at heat below redness (ca 500°). Boil carbonaceous mass with HCl (1+2.5), filter into 500 mL vol. flask, and wash with hot  $\text{H}_2\text{O}$ . Return residue, together with paper, to Pt dish, and burn to white ash. Boil again with the dil. HCl, filter, wash, combine filtrates, and dil. to 500 mL. Incinerate residue after last filtration and weigh ash insol. in acid.

**8.028 Iron and Aluminum (17)—Official Final Action**

Sep.  $\text{SiO}_2$ , if necessary, from 100 mL aliquot prepd soln, 8.027. Mix soln with excess 10%  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  soln. Add  $\text{NH}_4\text{OH}$  until permanent ppt is obtained, then HCl dropwise until ppt

dissolves. Bring soln to bp and boil 2–3 min; mix with considerable excess 50%  $\text{NH}_4\text{OAc}$  soln, **8.021(a)**, and 4 mL  $\text{HOAc}$  (4+1). As soon as ppt of  $\text{AlPO}_4$ , mixed with  $\text{FePO}_4$ , settles, collect on filter, wash with hot  $\text{H}_2\text{O}$ , ignite, and weigh. Fuse mixed phosphates with 10 parts  $\text{Na}_2\text{CO}_3$ , dissolve in  $\text{H}_2\text{SO}_4$  (1+6); reduce with Zn, and det. Fe by titrn with std  $\text{KMnO}_4$  soln (1 mL = 1 mg Fe). Det.  $\text{P}_2\text{O}_5$  in aliquot from **8.027** as in **8.033** or **7.119**.

Wt  $\text{Al}_2\text{O}_3$  = wt mixed phosphates – wt ( $\text{Fe}_2\text{O}_3$  +  $\text{P}_2\text{O}_5$ ).

#### 8.029 Calcium (71)—Official Final Action

Heat combined filtrate and washings obtained in **8.028** to  $50^\circ$ , and add excess *satd*  $\text{NH}_4$  oxalate soln. Let stand in warm place until ppt settles, filter, wash ppt with hot  $\text{H}_2\text{O}$ , dry, and ignite over Bunsen burner and finally over blast lamp at  $\geq 950^\circ$ . Cool in desiccator and weigh as  $\text{CaO}$ .

#### 8.030 Potassium and Sodium (71)—Official Final Action

Evap. aliquot prepd soln, **8.027**, nearly to dryness to remove excess  $\text{HCl}$ , dil., and heat to bp. While soln is still boiling add 10%  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$  soln as long as ppt forms, and then enough *satd*  $\text{Ba}(\text{OH})_2$  soln to make liq. strongly alk. After ppt settles, filter, and wash with hot  $\text{H}_2\text{O}$ ; heat filtrate to bp, add enough  $(\text{NH}_4)_2\text{CO}_3$  soln (1 part  $(\text{NH}_4)_2\text{CO}_3$  in 5 parts  $\text{NH}_4\text{OH}$  soln (1+12)) to ppt all the Ba, filter, and wash with hot  $\text{H}_2\text{O}$ . Evap. filtrate to dryness and ignite residue below redness to remove  $\text{NH}_4$  salts. Add little  $\text{H}_2\text{O}$  and few drops  $(\text{NH}_4)_2\text{CO}_3$  soln to residue. Filter into weighed Pt dish, evap., ignite below redness, and weigh mixed K and Na chlorides.

Digest residue with hot  $\text{H}_2\text{O}$ , filter thru small filter, and dil. filtrate, if necessary, to provide  $\geq 20$  mL liq. for each 100 mg  $\text{K}_2\text{O}$ . Acidify with few drops  $\text{HCl}$  and add excess Pt soln (10.5 g  $\text{H}_2\text{PtCl}_6/100$  mL). Evap. on  $\text{H}_2\text{O}$  bath to thick paste; treat residue repeatedly with 80% alcohol, decanting thru weighed gooch or other filter; transfer ppt to filter, and wash thoroly with 80% alcohol. Dry 30 min at  $100^\circ$  and weigh. Calc. K found to its equiv. of  $\text{KCl}$  and subtract result from wt mixed chlorides to obtain wt  $\text{NaCl}$ .

#### Phosphorus—Official Final Action

##### 8.031

##### Reagents

(a) *Ammonium nitrate soln.*—Dissolve 100 g P-free  $\text{NH}_4\text{NO}_3$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(b) *Magnesia mixture.*—(1) Dissolve 55 g crystd  $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 140 g  $\text{NH}_4\text{Cl}$  and 130.5 mL  $\text{NH}_4\text{OH}$ , and dil. to 1 L. Or, (2) dissolve 55 g crystd  $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 140 g  $\text{NH}_4\text{Cl}$ , dil. to 870 mL, and add  $\text{NH}_4\text{OH}$  to each required portion of soln just before using, at rate of 15 mL/100 mL soln.

(c) *Ammonium hydroxide soln for washing.*—(1+9). Should contain  $\geq 2.5\%$   $\text{NH}_3$  by wt.

##### 8.032

##### Preparation of Solution

Mix 5 g sample with little  $\text{Mg}(\text{NO}_3)_2$  soln, **2.019**, dry, ignite, dissolve in  $\text{HCl}$  (1+2.5), and dil. to definite vol. In aliquot of soln det. P as in **8.033** or **7.119**.

##### 8.033

##### Determination

Pipet aliquot of prepd soln into 250 mL beaker; add  $\text{NH}_4\text{OH}$  in slight excess and barely dissolve ppt formed with few drops  $\text{HNO}_3$ , stirring vigorously. If  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$  has been used as solv., add ca 15 g cryst.  $\text{NH}_4\text{NO}_3$  or soln contg that amt. To hot soln add 70 mL molybdate soln, **7.118(a)**, for every 100 mg  $\text{P}_2\text{O}_5$  present. Digest 1 hr at ca  $65^\circ$  and test for complete pptn of  $\text{P}_2\text{O}_5$

by adding more molybdate soln to clear supernate. Filter, and wash with cold  $\text{H}_2\text{O}$  or preferably with the  $\text{NH}_4\text{NO}_3$  soln. Dissolve ppt on filter with  $\text{NH}_4\text{OH}$  (1+1) and hot  $\text{H}_2\text{O}$ , and wash into beaker to vol.  $\leq 100$  mL. Neutze with  $\text{HCl}$ , using litmus paper or *bromothymol blue* as indicator; cool, and from buret slowly add (ca 1 drop/sec), stirring vigorously, 15 mL magnesia mixt./100 mg  $\text{P}_2\text{O}_5$  present. After 15 min add 12 mL  $\text{NH}_4\text{OH}$  and let stand until supernate is clear (usually 2 hr); filter, wash ppt with  $\text{NH}_4\text{OH}$  (1+9) until washings are practically  $\text{Cl}$ -free, dry, burn at low heat, and ignite to const wt, preferably in furnace at  $950$ – $1000^\circ$ ; cool in desiccator, and weigh as  $\text{Mg}_2\text{P}_2\text{O}_7$ . Report as %  $\text{P}_2\text{O}_5$ .

#### 8.034 Qualitative Test—Official Final Action

Add 10 mL  $\text{H}_2\text{O}$  to 1–2 g sample in 150 mL beaker. Make just acid with  $\text{HNO}_3$ , filter, take equal vols filtrate and molybdate soln, **7.118(a)**, and warm at  $40$ – $50^\circ$ . Yellow ppt indicates presence of phosphate.

#### 8.035 Sulfate (72)—Official Final Action

Boil 5 g sample 1.5 hr with mixt. of 300 mL  $\text{H}_2\text{O}$  and 15 mL  $\text{HCl}$ . Filter, wash filter thoroly with hot  $\text{H}_2\text{O}$ , cool combined filtrate and washings, and dil. to 500 mL with  $\text{H}_2\text{O}$ . Det. sulfate in 100 mL aliquot as in **3.062**.

#### 8.036 Ammonia—Official Final Action

To 2 g sample in distn flask add 300–400 mL  $\text{H}_2\text{O}$  and excess of  $\text{NaOH}$  soln (1+1), connect with condenser, and distil into measured vol. std acid. Titr. excess acid in distillate with std alkali, using Me red.

#### 8.037 Arsenic—Official Final Action

Place 5 g sample directly in generator, **25.007(a)**; add 10 mL  $\text{H}_2\text{O}$ , little at time to prevent foaming over, and then 15 mL As-free  $\text{HCl}$ , adding it dropwise until foaming ceases. Heat on steam bath until drop of mixt., when dild and treated with I soln, does not show blue. Then dil. to ca 30 mL with  $\text{H}_2\text{O}$  and continue as in **25.010** or **25.012**, beginning with addn of KI reagent. Prep. blank and stds for comparison, using As-free  $\text{HCl}$  of same concn as that used in detn.

#### 8.038 Fluorine—Official Final Action

See **25.049**–**25.055**.

#### 8.039 Lead—Official Final Action

See **25.061**–**25.062** and **25.095**–**25.105**.

## 9. Beverages: Distilled Liquors

### SPIRITS

#### 9.001 Physical Examination—Procedure

Note and record following: (a) Color and depth of color; (b) odor—whisky, brandy, rum, etc., or foreign; (c) taste—whisky, brandy, rum, etc., or foreign.

#### Color (1)—Official Final Action

##### 9.002

##### Definition

Whisky color units are defined as  $10 \times A$  at 430 nm, measured in monochromatic light, of sample  $\frac{1}{2}$ " thick which has spectral color characteristics of an av. whisky free of turbidity.

This definition applies only to  $A$  values obtained with precise spectrophtr with band width of  $\leq 1$  nm at 430 nm, and whose wavelength and photometer scales have been checked and corrected by methods recommended by NBS, in LC-1017, Jan. 1967, and in SP260-41.

#### Potassium Dichromate Calibration Method

##### 9.003

##### Preparation of Standard Curve

Prep. solns of  $K_2Cr_2O_7$  in 0.01N  $H_2SO_4$  as follows:

Color Unit	g/L	Color Unit	g/L
1	0.0500	6	0.3000
2	0.1000	7	0.3500
3	0.1500	8	0.4000
4	0.2000	9	0.4500
5	0.2500	10	0.5000

Read  $A$  of these solns in spectrophtr at 430 nm against  $H_2O$ , using same size cell as used in detns. If other than  $\frac{1}{2}$ " cell is used, convert reading to this size. Plot color units against  $A$  or calc. av. factor for converting instrument reading to color units if straight line is obtained.

##### 9.004

##### Determination

Place sample, or sample dild with 50% alcohol, in cell and det.  $A$  against  $H_2O$ . Calc. color units, using factor or std curve.

#### Natural and Artificial Coloring Matter (Organic and Water-Soluble Color) (2)—Official Final Action

##### Spectrophotometric Method

##### 9.005

##### Apparatus

- (a) *Spectrophotometer*.—See 9.002.  
 (b) *Graduated cylinder*.—Cylindrical type of uniform diam., with pressed or molded base and  $\frac{3}{8}$  stopper. Distance from base to top is 285–295 mm. To contain 50 mL at 20°, graduated in 0.2 mL with each fifth mark distinguished by longer line; numbered from bottom upward at 2 mL intervals; error of graduations  $\leq 0.2$  mL at any point. (Available from SGA Scientific Inc., No. JC-9675.)

##### 9.006

##### Reagents

- (a) *n-Methyl propyl ketone*.—2-Pentanone, practical.  
 (b) *Saturated sodium chloride soln*.—Use USP or ACS NaCl.  
 (c) *Alcohol*.—MeOH, reagent grade, or alcohol, USP.

##### 9.007

##### Determination

Pipet 20 mL whisky into cylinder, 9.005(b). Add by pipet, in order, 10 mL satd NaCl soln, 0.5 mL HCl, and 10 mL Me Pr ketone. Immediately invert 10–15 times and let layers sep. Color in lower layer indicates presence of caramel, vegetable extrac-tives, or synthetic dye. Read vol. of org. layer within 1 hr and det. its  $A$  at 430 nm. If  $A$  is too great or if solv. layer is cloudy, dil. aliquot to known vol. with either 50% MeOH or 50% alcohol and read  $A$ .

##### 9.008

##### Calculation

*Example:* If from 20 mL sample, org. layer of 16.1 mL was obtained which had  $A$  of 0.420 in 1 cm cell after dildn 1+1 with 50% alcohol:  $(16.1 \times 0.420 \times 12.7 \times 2)/20 = 8.59$  color units (Lovibond number), where 12.7 is conversion factor to color units.

#### Specific Gravity (Apparent)—Official Final Action

##### 9.009

##### Apparatus

- (a) *Constant temperature water bath*.  
 (b) *Pycnometers*.—100 and 50 mL (Fig. 9:01).

##### 9.010

##### Calibration

Fill thoroly cleaned pycnometer with recently distd  $H_2O$ , stopper, and immerse in const temp.  $H_2O$  bath with bath level above graduation mark on pycnometer. After 30 min, remove stopper and with capillary tube adjust until bottom of meniscus is tangent to graduation mark. With small roll of filter paper, dry inside neck of pycnometer, stopper, and immerse in  $H_2O$  at room temp. 15 min. Remove pycnometer, dry, let stand 15 min, and weigh. Empty pycnometer, rinse with acetone, and dry thoroly in air with suction. Let empty flask come to room temp., stopper, and weigh. Wt in air of contained  $H_2O$  = wt filled pycnometer – wt empty pycnometer.

##### 9.011

##### Determination

Obtain wt sample as in 9.010.

Sp gr in air =  $S/W$ , where  $S$  = wt sample, and  $W$  = wt  $H_2O$ .

#### Alcohol by Volume

#### From Specific Gravity by Pycnometer (3) Official Final Action

##### 9.012

##### Apparatus

*Distillation apparatus*.—500 mL flask, connected thru bulb (Iowa State type is convenient) to vertically assembled Liebig condenser with jacket  $\geq 400$  mm long, inner tube  $9 \pm 1$  mm id, with adapter. Joints may be live rubber or  $\frac{3}{8}$ . Heat with elec.- or gas-operated unit.

##### 9.013

##### Determination

(Some samples do not require distn prior to detn, e.g., straight bourbon whisky; alcohol- $H_2O$  mixts contg traces of volatile ingredients.)

(a) *Samples containing 60% or less alcohol by volume*.—Calibrate 100 mL pycnometer, Fig. 9:01, as in 9.010, at one of

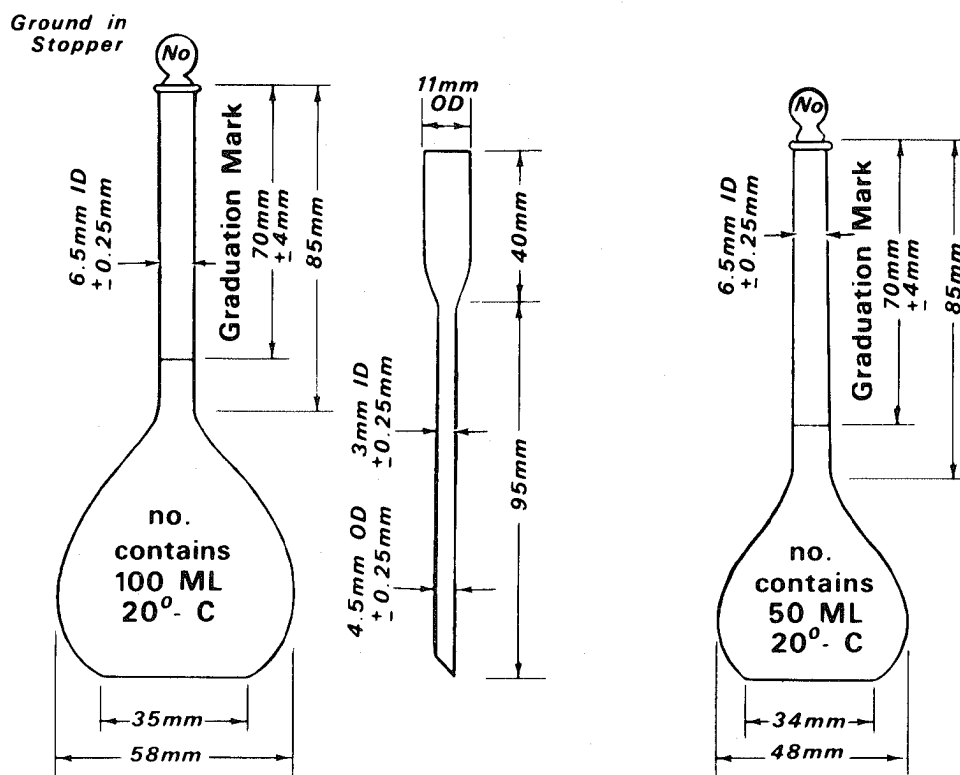

FIG. 9:01—100 mL and 50 mL pycnometers

temps specified in 52.003. Fill clean, dry pycnometer with sample and adjust to vol. at calibration temp. as in 9.010.

Transfer contents of pycnometer to distg flask, just previously rinsed with cold H<sub>2</sub>O and contg few glass beads, or equiv. Rinse pycnometer 3 times, using total of 25 mL cold H<sub>2</sub>O (40 mL for cordials or wines), and add rinse H<sub>2</sub>O to flask. Place wet pycnometer so that adapter extends just into bulb. Surround pycnometer with ice or ice-H<sub>2</sub>O. Complete connections and pass thru condenser rapid stream of H<sub>2</sub>O kept at ≤25° at outlet. Distill ca 96 mL at uniform rate in ≥30 but ≤60 min, using longer times for higher percentages of alcohol. Remove and stopper pycnometer, mix distillate by swirling, and wash down with H<sub>2</sub>O any drops that may be above graduation mark. Immerse in const temp. bath at calibration temp. and after 30 min carefully dil. to vol., with aid of capillary tube, by adding H<sub>2</sub>O previously boiled and cooled to same temp. Det. sp gr of distillate as in 9.011. Obtain corresponding % alcohol by vol. from 52.003. (This result is % alcohol by vol. at 15.56° (60°F).)

(b) *Samples containing more than 60% alcohol by volume.*—Proceed as in (a) with following changes: Calibrate 100 mL and 50 mL pycnometers, Fig. 9:01, at 15.56°, fill 50 mL pycnometer with sample, and adjust to vol. at 15.56°. Add 50 mL cold H<sub>2</sub>O to distg flask before transfer of sample and collect distillate in 100 mL pycnometer. Adjust to vol. at 15.56°. Obtain sp gr of distillate, and from table, 52.003, obtain % alcohol by vol. in distillate. Calc. as follows:

$$\% \text{ alcohol by vol. in sample at } 15.56^\circ = D \times W/W';$$

where  $D$  = % alcohol by vol. in distillate at 15.56°;  $W$  = wt H<sub>2</sub>O at 15.56° in 100 mL pycnometer; and  $W'$  = wt H<sub>2</sub>O at 15.56° in 50 mL pycnometer.

#### From Specific Gravity by Hydrometer (4) Official Final Action

(Applicable to spirits contg ≤600 mg ext/100 mL)

##### 9.014

##### Apparatus

- (a) *Hydrometer.*—Graduated to 0.1 or 0.2° proof, with calibration corrections.
- (b) *Thermometer.*—Graduated to 0.25 or 0.5°F, with calibration corrections.
- (c) *Cylinder.*—Clear glass, 2.5" diam., 14" high.
- (d) *Metal clips.*—To hold thermometer in cylinder.

##### 9.015

##### Determination

Clean and dry hydrometer before use. Let hydrometer, thermometer, cylinder, and sample come to room temp. Rinse cylinder, contg thermometer held in place by spring frame clip, 2 or 3 times with portion of sample. Fill cylinder to desired level with sample, holding cylinder at ca 45° angle to reduce agitation and air bubbles. (After hydrometer is inserted, liq. level should be slightly below rim of cylinder.) Place palm of hand over top of cylinder and slowly invert 3 or 4 times to equalize temps of liq. and cylinder. Wipe off any liq. on outside of cylinder. (Do not place hands on cylinder in such way as to warm liq. inside.) Insert hydrometer in liq.; then raise and lower hydrometer bulb from top to bottom 5 or 6 times to temper and distribute slight temp. changes thruout liq. Keep hydrometer bulb in liq., dry stem, and let hydrometer come to rest without wetting more than few tenths degrees of exposed stem.

Read hydrometer, then thermometer. To read hydrometer

scale, place eye slightly below plane of surface of liq., and then slowly raise head, keeping eye perpendicular to hydrometer, until surface flattens from ellipse into straight line. Take point where this line intersects hydrometer scale as reading of hydrometer.

Raise hydrometer slightly above its point of rest and again let it come to rest in liq. Read hydrometer and thermometer again to verify original readings. Read hydrometer to nearest 0.02° and thermometer to nearest 0.1°. Remove and dry hydrometer. Reinvert cylinder and contents several times (with thermometer left in place) to thermally equilibrate system. Retemper hydrometer, dry stem, and again read hydrometer and thermometer. Apply calibration corrections for both hydrometer and thermometer. Calc. true % of proof from Table No. 1 of the U.S. Treasury Department Gauging Manual, 1970. Average calcd values if they agree within 0.1° proof; otherwise take addnl readings and average.

Det. ext as in 9.022, and for every 100 mg ext/100 mL add 0.4° proof to apparent proof.

#### 9.016 From Refraction—Official Final Action

Measure 25 mL sample into distn flask, noting temp.; dil. with 100 mL H<sub>2</sub>O, distil nearly 100 mL, dil. to vol. at same temp., and det. immersion refractometer reading. Obtain corresponding % alcohol from 52.004.

When vol. measurements are made at temp. other than 15.56°, multiply % alcohol from 52.004 by appropriate factor from Table 9.01.

#### Williams Field Test (5)—Procedure

##### 9.017

##### Apparatus

*Williams tube.*—See Fig. 9.02. Available from Kontes Glass Co., No. K-899400. Clean frequently and dry.

##### 9.018

##### Reagents

(a) *Dilute hydrochloric acid.*—Dil. 10 mL HCl to 100 mL with H<sub>2</sub>O.

(b) *Solvent.*—Mix 70 mL Pentasol or isoamyl alcohol, 28 mL toluene, and 2 mL dil. HCl. Shake well until acid completely dissolves.

##### 9.019

##### Determination

Place sample in tube, accurately adjusting bottom of meniscus to coincide with 7.5 mL mark. Remove any excess sample on sides of tube above 7.5 mL mark with swab or roll of filter paper. Add solv. to 15 mL mark. Stopper tube and invert number of

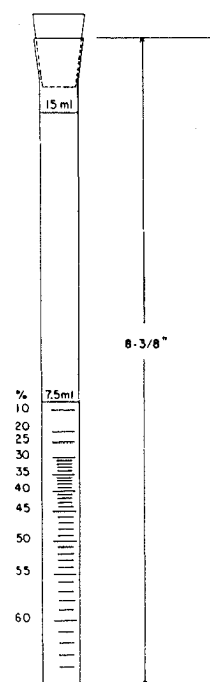

FIG. 9.02—Williams tube

times to mix intimately. Stand tube upright and let sep. When sepn is complete, rotate tube to shake down globules of lower soln that adhere to sides, and stopper. When settling and drainage are complete, read % alcohol (by vol.) where meniscus between the 2 layers falls on calibration mark. Repeat mixing and settling, and read again.

##### 9.020

##### Temperature Correction

Correct for temp. and alcohol concn according to Table 9.02.

*Example:* % alcohol from tube: 48.0% at 90°F. Correction factor from table: -1.1; 48.0 - 1.1 = 46.9%.

#### 9.021 Alcohol by Weight—Official Final Action

Accurately weigh 40–50 g sample in clean, dry 50 mL pycnometer, Fig. 9.01, or other closed vessel. (If alcohol is ≤60% by vol., the 100 mL sample of 9.013(a) may be weighed and used.) Transfer to 500 mL distn flask contg 50 mL H<sub>2</sub>O and few

Table 9.01 Factors for calculating original alcohol content for 25 and 50 mL samples distilled to 100 mL when refractometer measurements are made at 20, 25, 30, or 35°

clean glass beads, or equiv. Rinse pycnometer 3 times, bringing contents of distn flask to ca 125 mL. Distil, and det. % alcohol by vol. in distillate as in 9.013(a). Det. corresponding % alcohol by wt in distillate from table, 52.005. Multiply result by wt distillate and divide by wt sample.

**9.022 Extract—Official Final Action**

Weigh, or measure at 20°, 25–100 mL sample, evap. to dryness on steam bath, dry 30 min at 100°, cool in desiccator 30 min, and weigh.

**9.023 Ash—Official Final Action**

Proceed as in 31.012 or 31.013, using residue from 9.022.

**Potassium****Flame Photometric Method (6)—Official Final Action****9.024 Reagent and Apparatus**

(a) *Std solns.*—Prep. as in 11.024(a), except make final dilns, i.e., 1–10 ppm K, with 50% alcohol.

(b) *Flame spectrophotometer.*—See 11.024(b).

**9.025 Determination**

(Caution: See 51.007.)

Proceed as in 11.025, except burn sample undild, or, if necessary, dild with 50% alcohol (usually 2.5–5.0 times). Calc. ppm K as in 11.025.

**Sodium****Flame Photometric Method (6)—Official Final Action****9.026 Reagent and Apparatus**

(a) *Std solns.*—Prep. as in 11.026, except make final dilns, i.e., 1–10 ppm Na, with 50% alcohol.

(b) *Flame spectrophotometer.*—See 11.024(b).

**9.027****Determination**

(Caution: See 51.007.)

Proceed as in 11.025, except burn sample undild, or, if necessary, dild with 50% alcohol until %T falls within %T range of stds. Calc. ppm Na as in 11.025.

**9.028 Phosphorus—Official Final Action**

See 11.034.

**Copper—Official Final Action****Atomic Absorption Method (7)****9.029****Reagent**

(Distil H<sub>2</sub>O and alcohol from all-Pyrex stills into Cu-free receiver.)

*Copper std solns.*—(1) *Stock soln.*—0.2 mg/mL. Dissolve 0.393 g CuSO<sub>4</sub>·5H<sub>2</sub>O (free from any whitish deposit) in 500 mL vol. flask contg H<sub>2</sub>O and 2 mL H<sub>2</sub>SO<sub>4</sub>. Dil. to vol. and mix. (2) *Working soln.*—0.004 mg/mL. Prep. daily by dilg 2.00 mL stock soln to 100 mL.

**9.030****Preparation of Standard Curve**

To series of 50 mL vol. flasks each contg 25 mL alcohol, add 0, 2, 4, 6, 10, and 12 mL Cu working std soln. Dil. nearly to mark with H<sub>2</sub>O, mix, and cool to room temp. before dilg to vol. Std contain 0.0, 0.16, 0.32, 0.48, 0.80, and 0.96 ppm Cu (μg/mL), resp.

**9.031****Determination**

(Caution: See 51.006.)

Follow operating instructions supplied by manufacturer or previously established optimum settings for AA spectrophtr used. Adjust instrument to 0 A while aspirating blank. Read at 324.7 nm ≥4 std solns within anal. range before and after each 6–10 samples. Prep. calibration curve from av. of each std before and after sample group. Use std curve to convert A values for samples to ppm Cu.

**ZDBT Colorimetric Method (8)****9.032****Reagents**

Prep. H<sub>2</sub>O, alcohol, and Cu stds as in 9.029, and in addn:  
*Zinc dibenzylthiocarbamate (ZDBT)-carbon tetrachloride soln.*—0.2%. Dissolve 2 g ZDBT (Uniroyal Chemical or ICN-K&K Laboratories) in 1 L CCl<sub>4</sub> by warming in H<sub>2</sub>O bath at <77°. Filter thru Whatman No. 41, or equiv. acid-washed paper, into dark bottle. Store in refrigerator.

**9.033****Apparatus**

*Separators.*—60 or 125 mL pear-shaped separators with Teflon stopcocks. Clean separators with hot chromic acid cleaning soln and rinse with H<sub>2</sub>O. Before each analysis, shake mixt. of 10 mL H<sub>2</sub>O, 0.5 mL 6*N* H<sub>2</sub>SO<sub>4</sub>, and 10 mL ZDBT-CCl<sub>4</sub> soln in each separator 1 min. Clean inside of stems with cotton swab soaked in ZDBT-CCl<sub>4</sub> soln. Drain and rinse separators with H<sub>2</sub>O.

**9.034****Preparation of Standard Curves**

(a) *80–135° proof alcoholic samples.*—To separators contg 5 mL alcohol, add 0, 0.50, 1.00, 2.00, and 3.00 mL Cu working std soln and 5, 4.5, 4, 3, and 2 mL H<sub>2</sub>O, resp. Solns in separators contain 0.0, 0.20, 0.40, 0.80, and 1.20 µg Cu/mL (ppm), resp. Treat as in 9.035. Plot ppm Cu against A.

(b) *Aqueous samples, wines, and other low proof samples.*—Prep. as in (a) except use 5 mL H<sub>2</sub>O instead of alcohol.

**9.035****Determination**

To separator contg 10 mL sample (dil. sample >135° proof to 80–135° proof) or std, add 0.5 mL 6*N* H<sub>2</sub>SO<sub>4</sub> and 10.0 mL ZDBT-CCl<sub>4</sub> soln. Stopper and shake briefly; release pressure by removing stopper. Replace stopper and shake vigorously 100 times. If funnel stems are not dry, remove drops of liq. with small roll acid-washed paper (e.g., Whatman 41) to prevent draining H<sub>2</sub>O drops into cell. Insert plug of fibre glass (Corning Glass Works No. 3950) or cotton into each stem to filter out possible haze materials. Within 10–60 min, det. A of CCl<sub>4</sub> layer at 438 nm. Let few mL CCl<sub>4</sub> layer pass thru filtering medium before collecting sample in cell. Use CCl<sub>4</sub> layer from appropriate 0 ppm Cu soln (prepd as for std curve (a) or (b)) as ref. Det. Cu concn from appropriate std curve. Multiply by diln factor if sample was dild.

**Iron (9)—Official Final Action****Atomic Absorption Method****9.036****Apparatus**

*Spectrophotometer.*—Perkin-Elmer Corp. 303 (or later double beam model), or equiv., with 3-slot Belling burner head, or equiv.

**9.037****Reagent**

(Use Fe-free H<sub>2</sub>O and reagents; rinse glassware with HCl and H<sub>2</sub>O before use.)

*Iron std solns.*—(1) *Stock soln.*—10 µg/mL. Dissolve 0.0684 g ferrous ethylenediammonium sulfate (FeC<sub>2</sub>H<sub>4</sub>(NH<sub>3</sub>)<sub>2</sub>SO<sub>4</sub>·4H<sub>2</sub>O, G. Frederick Smith Chemical Co.) in H<sub>2</sub>O, add 2.5 mL H<sub>2</sub>SO<sub>4</sub>, dil. to 1 L with H<sub>2</sub>O, and mix thoroly. (2) *Working solns.*—0.0, 0.1, 0.2, 0.3, and 0.4 ppm. To 100 mL vol. flask contg 50 mL 43% alcohol, add 0, 1, 2, 3, and 4 mL stock soln and dil. each soln nearly to vol. with 43% alcohol. Mix thoroly, let cool to room temp., and adjust to 100 mL with 43% alcohol.

**9.038****Determination**

(Caution: See 51.006.)

Follow manufacturer's operating instructions, using lean air-C<sub>2</sub>H<sub>2</sub> flame and single element Fe lamp. Set wavelength at 248.3 nm and adjust spectrophtr to 0 A while aspirating blank (0.0 ppm Fe). Analyze stds before and after duplicate series of samples. Det. av. A values. Aspirate H<sub>2</sub>O between each detn to flush burner, and reset A to 0 with blank. Plot std curve of A against ppm Fe. Read ppm Fe in sample from this curve.

**TPTZ Colorimetric Method**

(Not applicable to brandy)

**9.039****Apparatus**

(a) *Spectrophotometer.*—Beckman Instruments Model DU, or equiv., or photoelec. colorimeter with suitable filter, e.g., Klett colorimeter with No. 60 filter.

(b) *Water bath.*—To maintain const temp. at ca 60°.

**9.040****Reagents**

(Use Fe-free H<sub>2</sub>O and reagents; rinse glassware with HCl and H<sub>2</sub>O before use.)

(a) *Hydroxylamine hydrochloride soln.*—40%. Dissolve 10 g NH<sub>2</sub>OH·HCl in 25 mL H<sub>2</sub>O.

(b) *Ammonium perchlorate soln.*—10%. Dissolve 10 g NH<sub>4</sub>ClO<sub>4</sub> in 100 mL H<sub>2</sub>O.

(c) *1,2-Propanediol cyclic carbonate (propylene carbonate).*—Reagent grade (MC/B Manufacturing Chemists).

(d) *2,4,6-Tripyridyl-s-triazine (TPTZ) soln.*—0.001*M*. Add 0.0781 g TPTZ (G. Frederick Smith Chemical Co.) to 100 mL H<sub>2</sub>O contg 5 drops HCl in 250 mL vol. flask. Dil. to vol. with H<sub>2</sub>O and filter thru coarse fritted glass funnel. Store in Fe-free glassware.

(e) *Sodium acetate soln.*—40%. Dissolve 48.2 g anhyd. NaOAc in 75.7 mL H<sub>2</sub>O and 24.3 mL HCl. Add 5 mL 0.001*M* TPTZ, 5 mL 40% NH<sub>2</sub>OH·HCl, 2 mL 10% NH<sub>4</sub>ClO<sub>4</sub>, and 10 mL propylene carbonate. Add 5 mL CHCl<sub>3</sub>, shake, and discard lower layer. After 2 CHCl<sub>3</sub> extns, add 5 mL 0.001*M* TPTZ and repeat CHCl<sub>3</sub> extn. (Four extns are necessary to obtain colorless soln.) Store in Fe-free glassware.

(f) *Ascorbic acid solns.*—(1) 5%.—Dissolve 2.5 g ascorbic acid in 25 mL H<sub>2</sub>O and dil. to 50 mL with alcohol. Prep. fresh daily. (2) 5% *Ascorbic acid in sodium acetate buffer.*—Dissolve 2.5 g ascorbic acid in 20 mL H<sub>2</sub>O, add 5 mL 40% NaOAc, and dil. to 50 mL with alcohol. Prep. fresh daily.

(g) *Iron std solns.*—Prep. same concns as in 9.037, but prep. 200 mL each working soln.

**9.041****Preparation of Standard Curve**

Pipet 50 mL 43% alcohol contg known amts Fe (i.e., 0 (reagent color blank), 0.1, 0.2, 0.3, and 0.4 ppm) into 5 sep. 100 mL vol. flasks. Add 2 mL 5% ascorbic acid in NaOAc buffer and 2 mL TPTZ, and heat 15 min in ca 60° H<sub>2</sub>O bath.

Cool solns to room temp. and det. A on spectrophtr at 593 nm or photoelec. colorimeter with appropriate filter. Use 43% alcohol to zero colorimeter. Subtract A of reagent color blank from A of samples. Plot corrected A readings against ppm Fe to obtain std curve. (Straight line should be obtained with Fe concns used.)

**9.042****Determination**

Pipet 50 mL sample into each of 2 sep. 100 mL vol. flasks and add 2 mL 5% ascorbic acid to each. Add 2 mL TPTZ to one flask

and 2 mL H<sub>2</sub>O to other (product blank). Heat 15 min in ca 60° H<sub>2</sub>O bath. Cool solns and measure *A* of each soln as for std curve. Subtract *A* of reagent color blank, **9.041**, and also *A* of product color blank from *A* of samples. Det. Fe concn from std curve.

#### Chloride (10)—Official Final Action

##### 9.043

##### Apparatus

See **11.029**.

##### 9.044

##### Reagents

See **11.030** and in addn:

(a) *Dilute chloride std soln.*—Dil. 50 mL chloride std soln, **11.030(c)**, to 500 mL with H<sub>2</sub>O. Alternatively, dissolve 0.2103 g KCl in H<sub>2</sub>O and dil. to 1 L. 1 mL = 0.1 mg Cl.

(b) *Dilute silver nitrate std soln.*—Dil. 50 mL std soln, **11.030(d)**, to 500 mL with H<sub>2</sub>O. Alternatively, dissolve 0.4791 g AgNO<sub>3</sub> in H<sub>2</sub>O and dil. to 1 L. 1 mL = 0.1 mg Cl.

(c) *Alcohol soln.*—Place 500 mL alcohol in 1 L vol. flask, add ca 475 mL H<sub>2</sub>O, mix, cool to room temp., and dil. to 1 L with H<sub>2</sub>O.

##### 9.045

##### Determination

Det. equivalence point voltage as in **11.031** except use alcohol soln instead of H<sub>2</sub>O to adjust vol. to 100 mL. Use std solns **11.030(c)** and (d).

Pipet 5 mL dil. std Cl soln into 250 mL beaker, and add 95 mL alcohol soln and 1.0 mL HNO<sub>3</sub>. Tit. with dil. std AgNO<sub>3</sub> soln to predetd equivalence voltage as in **11.031**.

Pipet 100 mL distd spirits sample into 250 mL beaker, add 1.0 mL HNO<sub>3</sub>, and tit. with dil. std AgNO<sub>3</sub> soln as above.

$\text{Ppm Cl in sample} = (V_w/V_s) \times C \times 10$ ,

where  $V_w$  = mL std AgNO<sub>3</sub> used by sample,  $V_s$  = mL std AgNO<sub>3</sub> used by std Cl soln, and  $C$  = 0.5 mg Cl in 5 mL std Cl soln used.

#### 9.046 Total Acids—Official Final Action

Neutze ca 250 mL boiled H<sub>2</sub>O in porcelain evapg dish (185 mm dish is convenient). Add 25 mL sample and tit. with 0.1*N* NaOH, using ca 2 mL phthln.

#### 9.047 Fixed Acids—Official Final Action

Evap. 25–50 mL sample to dryness in Pt dish on steam bath and dry 30 min in oven at 100°. Dissolve and transfer residue with several portions of neut. alcohol of ca same proof as sample, using 25–50 mL in all, to porcelain dish contg ca 250 mL neutzd boiled H<sub>2</sub>O. Tit. with 0.1*N* NaOH, using 10 mL buret graduated in 0.05 mL, and ca 2 mL phthln.

#### 9.048 Volatile Acids—Official Final Action

Volatile acids = total acids from **9.046** – fixed acids from **9.047**.

#### Esters and Aldehydes—Official Final Action

##### 9.049

##### Reagents

(a) *Sodium thiosulfate std soln.*—0.05*N*. Prep. by dilg 0.1*N* soln, **50.037**.

(b) *Iodine soln.*—Approx. 0.05*N*.

(c) *Sodium bisulfite soln.*—Approx. 0.05*N*. (Deterioration is retarded if soln contains ca 10% alcohol; do not use after ca 1 week.)

##### 9.050

##### Preparation of Sample

To 200 mL sample in 500 mL erlenmeyer, add ca 35 mL H<sub>2</sub>O and few grains SiC (Carborundum). Distil slowly into 200 mL vol. flask until distillate is nearly at mark. Dil. to vol. and mix.

##### 9.051

##### Determination of Esters (11)

Transfer 100 mL distillate to 500 mL flask, neutze free acid, add measured excess 0.1*N* NaOH, connect flask with air-cooled condenser ca 60 cm long, heat 2 hr on steam bath, let cool, and tit. excess alkali. Reject detns in which excess 0.1*N* alkali is <2 mL, or is >10 mL. Calc. esters as EtOAc. Correct for blank detn performed on 100 mL 50% alcohol (absolute alcohol-H<sub>2</sub>O, 1+1).

##### 9.052

##### Determination of Aldehyde

##### (Indirect Method)

Place remainder of distillate from **9.050** in 500 mL flask, add ca 100 mL H<sub>2</sub>O and excess NaHSO<sub>3</sub> soln, and let stand ca 30 min, shaking occasionally. (Excess NaHSO<sub>3</sub> should be equiv. of ca 25 mL I soln.) Add excess I soln, and tit. this excess with std Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln. Run blank contg same vols of I soln and bisulfite soln as used in sample. Difference between titrns in mL Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln × 1.1 = mg acetaldehyde in sample.

#### Esters

#### Spectrophotometric Method (12)—Official Final Action

##### 9.053

##### Principle

Esters react quant. with H<sub>2</sub>NOH in alk. soln to form a hydroxamic acid which, after acidification, forms colored complex with ferric ions. Ester concn is proportional to *A* at 525 nm at const alcohol concn and can be calcd from either of 2 std curves: (1) *At constant proof.*—Plot *A* against known EtOAc concn in 100° proof spirits (or any other convenient const proof); or (2) *At any actual proof.*—Plot *A* of EtOAc/g against proof and calc. concn from this proof factor.

##### 9.054

##### Reagents

(a) *Hydrochloric acid.*—4*N*. Dil. 333 mL HCl to 1 L with H<sub>2</sub>O.

(b) *Ferric chloride soln.*—0.37*M*. Dissolve 50 g FeCl<sub>3</sub>·6H<sub>2</sub>O in ca 400 mL H<sub>2</sub>O in 500 mL vol. flask. Add 12.5 mL 4*N* HCl and dil. to vol. with H<sub>2</sub>O.

(c) *Hydroxylamine hydrochloride soln.*—2*M*. Dissolve 69.6 g H<sub>2</sub>NOH·HCl in H<sub>2</sub>O in 500 mL vol. flask and dil. to vol. with H<sub>2</sub>O. Store in refrigerator.

(d) *Sodium hydroxide soln.*—3.5*N*. Dissolve 70 g NaOH in ca 400 mL H<sub>2</sub>O in 500 mL vol. flask. Cool, and dil. to vol. with H<sub>2</sub>O.

##### 9.055

##### Preparation of Ethyl Acetate Standard Solutions

(a) *Stock soln No. 1 for std curve.*—0.333 g EtOAc/L in 100° proof spirits. Weigh 0.1667 g EtOAc in weighing bottle and transfer quant. to 500 mL vol. flask with 100° proof spirits. Dil. to vol. with 100° proof spirits at room temp.

(b) *Std solns for std curve.*—To series of five 100 mL vol. flasks add, from pipet or buret, 0.0, 15.0, 30.0, 45.0, and 60.0 mL stock soln No. 1. Dil. to vol. with 100° proof spirits and mix. Stds contain 0.0, 5.0, 10.0, 15.0, and 20.0 g EtOAc/100 L, resp.

(c) *Stock soln No. 2 for proof factor determination.*—0.500 g EtOAc/L H<sub>2</sub>O. Weigh 0.2500 g EtOAc in weighing bottle and

transfer quant. to 500 mL vol. flask with H<sub>2</sub>O. Dil. to vol. with H<sub>2</sub>O and mix.

(d) *Stock soln No. 3 for proof factor determination.*—0.500 g EtOAc/L 192° proof spirits. Prep. as in (c), using 192° proof spirits for transfer and diln.

(e) *Proof factor std solns.*—(1) 0–50° stds.—To 6 sep. 250 mL vol. flasks add 50.0 mL EtOAc stock soln No. 2. Using graduate, add 0, 13, 20, 39, 53, and 66 mL 192° proof spirits. Dil. each nearly to vol. with H<sub>2</sub>O, mix, and cool to room temp. before dilg to vol. with H<sub>2</sub>O. Std solns contain 10 g EtOAc/100 L in ca 0, 10, 20, 30, 40, and 50° proof spirits. (2) 60–192° stds.—To 9 sep. 250 mL vol. flasks, add 50.0 mL EtOAc stock soln No. 3. Using appropriate graduate, add 29, 55, 81, 108, 134, 161, 174, 187, and 200 mL 192° proof spirits, resp. Dil. nearly to vol. with H<sub>2</sub>O, mix, and cool to room temp. before dilg to vol. with H<sub>2</sub>O. Std solns contain 10 g EtOAc/100 L in ca 60, 80, 100, 120, 140, 160, 170, 180, and 192° proof spirits, resp.

Det. exact proof of solns by std method, e.g. hydrometer.

## 9.056

### Preparation of Samples

Analyze whisky distillates, spirits, and colorless gin samples directly. Distil colored or turbid samples as in 9.050. If sample contains >20 g ester/100 L, dil. with H<sub>2</sub>O to ester concn of 5–20 g/100 L.

## 9.057

### Determination

(Mix all solns by swirling to avoid formation of bubbles.)

Just before use, prep. stock soln of reaction mixt. by combining 5.0 mL H<sub>2</sub>NOH.HCl and 5.0 mL 3.5*N* NaOH for each std and sample soln. Discard after 6 hr.

Prep. ref. soln by pipetting 4 mL reaction mixt. and 2 mL 4*N* HCl into 25 × 200 mm test tube. Mix and add 2.0 mL sample. Same ref. soln may be used for series of samples of different ester content, but they must have same proof.

Pipet 2 mL sample and 4 mL reaction mixt. into another 25 × 200 mm test tube. Mix and let react 1–20 min. Pipet in 2 mL 4*N* HCl and mix.

To ref. soln, pipet in 2 mL FeCl<sub>3</sub> soln. Rinse ref. cell twice with this soln, fill cell, and place in cell holder. This ref. soln may be used for 1 day if tightly capped; otherwise refill periodically to avoid evapn error.

To sample soln, pipet in 2 mL FeCl<sub>3</sub> soln and mix. Complete reading of each sample before proceeding to next. Rinse sample cell twice, fill cell, and place in cell holder. Read *A* at 525 nm immediately, since color of sample fades rapidly. If instrument has single cell or tube, use same cell or tube for both ref. and sample. Calc. or obtain  $\Delta A = A_{\text{sample}} - A_{\text{ref.}}$

## 9.058

### Preparation of Standard Curve

Analyze std solns, 9.055(b), as in 9.057. Plot  $\Delta A$  against EtOAc concn (g/100 L at 100° proof). (Note: Std curve need not be repeated for each analysis. Check periodically and repeat if new instrument or reagents are used.)

## 9.059

### Preparation of Proof Factor Curve

Analyze std solns, 9.055(e), as in 9.057. Plot  $\Delta A/g$  EtOAc against proof in the 15 solns (0–192° proof). See Note, 9.058.

To calc. ester content of samples, read *A/g* value from proof factor curve at sample proof. If sample was dild, use dild proof in calcn. Divide observed *A* by *A/g* to obtain g EtOAc/100 L. Correct for sample diln, if necessary. To express as g/100 L at 100° proof, multiply above ester value by ratio: 100/sample proof.

## Aldehydes—Official Final Action

### Method I (13)

(Applicable to ext-free spirits—brandy and wine spirits)

## 9.060

### Reagents

(a) *Potassium metabisulfite soln.*—Dissolve 15 g K<sub>2</sub>S<sub>2</sub>O<sub>5</sub> in H<sub>2</sub>O, add 70 mL HCl, and dil. to 1 L with H<sub>2</sub>O. Bisulfite titer of 10 mL soln should be  $\geq 24$  mL 0.1*N* I soln.

(b) *Phosphate-EDTA soln.*—Dissolve 200 g Na<sub>3</sub>PO<sub>4</sub>·12H<sub>2</sub>O (or 188 g Na<sub>2</sub>HPO<sub>4</sub>·12H<sub>2</sub>O + 21 g NaOH; or 72.6 g NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O + 42 g NaOH; or 71.7 g KH<sub>2</sub>PO<sub>4</sub> + 42 g NaOH) and 4.5 g Na<sub>2</sub>H<sub>2</sub>EDTA in H<sub>2</sub>O and dil. to 1 L.

(c) *Dilute hydrochloric acid.*—Dil. 250 mL HCl to 1 L with H<sub>2</sub>O.

(d) *Sodium borate soln.*—Mix 100 g H<sub>3</sub>BO<sub>3</sub> with 170 g NaOH and dil. to 1 L with H<sub>2</sub>O.

## 9.061

### Total Aldehydes

Pipet 50 mL sample (contg  $\leq 30$  mg acetaldehyde), reduced to ca 100° proof, or 25 mL high proof sample and 25 mL H<sub>2</sub>O, into 750 mL or 1 L erlenmeyer contg 300 mL boiled or deaerated H<sub>2</sub>O and 10 mL K<sub>2</sub>S<sub>2</sub>O<sub>5</sub> soln. Stopper flask, swirl to mix, and let stand 15 min. Add 10 mL phosphate-EDTA soln. (pH should be 7.0–7.2. If not, adjust pH by adding HCl or NaOH soln to K<sub>2</sub>S<sub>2</sub>O<sub>5</sub> soln and start with new sample.) Stopper flask, swirl, and let stand addnl 15 min. Add 10 mL HCl, (c) (when analyzing series, make complete detn on first sample before adding acid to next), and ca 10 mL fresh 0.2% starch indicator. Swirl to mix. Add enough ca 0.1*N* I soln to just destroy excess bisulfite and bring soln to light blue end point.

Add 10 mL Na borate soln, and rapidly titr. liberated bisulfite with 0.05*N* I soln from 10 mL buret (or 0.02*N* I soln from 25 mL buret) to same light blue end point as above, swirling gently and continuously, avoiding direct sunlight. (pH should be 8.8–9.5. If necessary, adjust by adding HCl or NaOH soln to Na borate soln and start with fresh sample.)

$\text{mg CH}_3\text{CHO}/100 \text{ mL} = \text{mL I soln} \times \text{normality I soln} \times 22.0 \times 100/\text{mL sample.}$

## 9.062

### Free Aldehydes

Pipet identical sample as in 9.061 into 750 mL or 1 L erlenmeyer contg 300 mL boiled or deaerated H<sub>2</sub>O and 10 mL each K<sub>2</sub>S<sub>2</sub>O<sub>5</sub> and phosphate-EDTA solns. Stopper flask, swirl, and let stand 15 min. Proceed as in 9.061, beginning "Add 10 mL HCl, (c) . . ."

### Method II

(Applicable to spirits contg ext—aged in wood)

## 9.063

### Free Aldehydes

Pipet 50 mL sample (contg  $\leq 30$  mg acetaldehyde), reduced to 80–100° proof, if necessary, into 500 mL distg flask, add 50 mL satd borax soln, and distil ca 50 mL into 750 mL or 1 L erlenmeyer contg 300 mL H<sub>2</sub>O and 10 mL each K<sub>2</sub>S<sub>2</sub>O<sub>5</sub> and phosphate-EDTA solns. (pH should be 7.0–7.2. If necessary, adjust by adding HCl or NaOH soln to K<sub>2</sub>S<sub>2</sub>O<sub>5</sub> soln and start with fresh sample.) Proceed as in 9.061, beginning "Add 10 mL HCl, (c) . . ."

## 9.064

### Aldehydes as Acetal

Transfer 200 mL sample measured at std temp. in vol. flask to 500 mL distg flask, and rinse vol. flask 2–3 times with small amts H<sub>2</sub>O into distg flask. Add 50 mL satd borax soln and distil,

slowly at first, nearly 200 mL into same vol. flask contg 2–3 mL H<sub>2</sub>O and immersed in ice bath. Bring distillate to vol. at same temp. used for measuring sample.

Det. total aldehydes (including acetal) as in 9.061. Det. free aldehydes as in 9.062. Total aldehydes – free aldehydes = combined aldehydes equiv. to acetal as mg CH<sub>3</sub>CHO/100 mL. Alternatively, combined aldehydes as acetal/100 mL = (combined aldehydes equiv. to acetal as mg CH<sub>3</sub>CHO/100 mL) × 2.68.

**9.065****Total Aldehydes**

Report total aldehydes as sum of free aldehydes, 9.063, and combined aldehydes equiv. to acetal, 9.064.

**Fusel Oil—Official Final Action****Method I (14)****9.066****Reagents**

(a) *p*-Dimethylaminobenzaldehyde (DMAB) soln.—In 100 mL vol. flask dissolve 1 g DMAB in mixt. of 5 mL H<sub>2</sub>SO<sub>4</sub> and 90 mL H<sub>2</sub>O, and dil. to vol. with H<sub>2</sub>O.

(b) *Isobutyl alcohol*.—Eastman Kodak Co. 303 (highest purity for fusel oil assay).

(c) *Isoamyl alcohol*.—Eastman Kodak Co. X-18, isopentyl alcohol (highest purity for fusel oil assay).

(d) *Ethyl alcohol*.—Redistd middle 50% fraction.

(e) *Synthetic std fusel oil*.—Weigh 2 g std isobutyl alcohol and 8 g std isoamyl alcohol into 1 L vol. flask and dil. to vol. with H<sub>2</sub>O. Pipet two 10 mL portions into 100 mL vol. flasks and dil. to vol., one with H<sub>2</sub>O and other with alcohol. Prep. working stds for products in range of 0–170 proof contg 1.0–6.0 g synthetic fusel oil/100 L by dilg 1.0–6.0 mL aliquots of aq. std soln to 100 mL with alc. soln of proof expected for dild sample when pipetted into analysis tube. Prep. similar working stds for products in range of 170–190 proof by dilg 1.0–6.0 mL aliquots of alc. std soln to 100 mL with alc. soln of proof of sample or its dild.

When 6 mL synthetic std dild with 190 proof alcohol is analyzed, *A* should be 0.83 ± 0.03 at 530 nm.

**9.067****Preparation of Samples**

(Aged, blended and rectified products, whiskies, brandies, rums, vodka, and liqueurs require distn prior to analysis.)

*Determination of true proof of sample*.—Det. alcohol as in 9.013.

For samples contg >6 g fusel oil/100 L, dil. distd sample with H<sub>2</sub>O to concn of 2.0–5.0 g fusel oil/100 L. Dil. 5 mL brandy, rum, or blended whisky to 100 mL; dil. 5 mL heavy brandy, rum, or straight whisky to 250 mL.

**9.068****Determination**

Pipet 2 mL aliquots of sample or dild sample, distd, if necessary, 2 mL H<sub>2</sub>O (for reagent blank), and 2 mL aliquots of stds into 15 × 150 mm g-s or covered test tubes. Stopper or cover tubes, and place in rack, then in ice bath. Pipet 1 mL DMAB soln into each tube, shake, and replace in ice bath for 3 min. With tubes still in ice bath, add 10 mL chilled H<sub>2</sub>SO<sub>4</sub> from buret down side of tubes. Shake tubes individually and replace in ice bath for 3 min. Transfer rack of tubes from ice bath to boiling H<sub>2</sub>O bath and boil 20 min. Transfer tubes to ice bath for 3–5 min, then to room temp. bath. Read %*T* of developed color of samples and stds on spectrophtr at 538–543 nm against reagent blank as ref. (Use same wavelength for both stds and unknowns.)

Plot g fusel oil in std samples/100 L on linear scale as abscissa against %*T* as ordinate on log scale of semilog paper. Convert %*T* of samples to g fusel oil/100 L from std curve. If dild was used, multiply g fusel oil/100 L found by dild factor to obtain g fusel oil/100 L in original sample. Analyze 2 levels of stds with each series of unknowns.

Precision expected: Whisky and brandy, ±5%; rum, ±8%; gin, vodka, and spirits, ±0.4 g/100 L.

**Method II (15)****9.069****Reagents**

(a) *Color reagent*.—Dissolve 1 g Na salt of 4-hydroxybenzaldehyde-3-sulfonic acid in H<sub>2</sub>O, dil. to vol. in 25 mL vol. flask with H<sub>2</sub>O, and filter.

(b) *Fusel oil std solns*.—Weigh 2 g isobutyl alcohol, 9.066(b), and 8 g isoamyl alcohol, 9.066(c), into 1 L vol. flask and dil. to vol. with 50% alcohol. Dil. 0, 1, 2, 3, 5, 10, and 15 mL portions to vol. with 50% alcohol in 100 mL vol. flasks (0.0, 0.1, 0.2, 0.3, 0.5, 1.0, and 1.5 g fusel oil/L). Std soln contg 1.0 g fusel oil/L should give *A* of ca 0.4 at 445 nm in 9.071.

(c) *Alcohol*.—50%. Free of fusel oil (ACS).

**9.070****Preliminary Distillation**

Add 20 mL H<sub>2</sub>O to 50 mL sample and distil, slowly at first, collecting ca 50 mL in 50 mL vol. flask. Dil. to vol. with H<sub>2</sub>O. (For samples known to contain >150 g fusel oil/100 L, use 25 mL sample plus 45 mL H<sub>2</sub>O.)

**9.071****Determination**

To dry 10 mL vol. flask, add 0.1 mL distillate from serological blow-out pipet. (Pipet should have pointed tip and should be thoroly cleaned (chromic acid plus H<sub>2</sub>O rinse) before use. Rinse pipet several times with distillate, and wipe end dry. Bring liq. to line while holding tip to outside surface of vol. flask. Then insert end to bottom of vol. flask and release sample. After draining pipet, hold flask at 45° angle and blow out pipet.)

Add 0.1 mL color reagent from 1 mL buret graduated in 0.01 mL; then add 2 mL H<sub>2</sub>SO<sub>4</sub> from 50 mL buret. Mix, and place unstoppered flask in H<sub>2</sub>O bath at room temp. (250 mL beaker is convenient). Bring to bp and boil 30 min. Let cool, dil. to vol. with H<sub>2</sub>SO<sub>4</sub>, and det. *A* at 445 nm against H<sub>2</sub>O on Beckman DU spectrophtr, or equiv. instrument.

**9.072****Blank and Standards**

Develop color of 0.1 mL 50% alcohol and 0.1 mL portions of std solns. Use same 0.1 mL pipet for blank, stds, and sample. Subtract *A* of 50% alcohol blank from *A* of sample and stds.

**9.073****Calibration Curve or Factor**

Plot corrected *A* of stds against concn. (Straight line is obtained up to ca 150 g fusel oil/100 L; above this value, curve flattens. Concn of color reagent may be increased, but it is best to dil. distd sample so that *A* is <0.6.) Calc. or obtain *A'* (*A* of 1.0 g fusel oil/L) from curve.

**9.074****Calculations**

$$\text{g fusel oil/100 L} = 100 A \times D/A'$$

where 100 = dild of 0.1 mL sample to 10 mL in color development, *A* = corrected *A* of sample, *A'* = factor, 9.073, and *D* = dild of sample before distn.

# Higher Alcohols (*n*-Propyl Alcohol, Isobutyl Alcohol, and Isoamyl Alcohol) and Ethyl Acetate—Official Final Action

## Gas Chromatographic Method (16)

### 9.075

#### Apparatus

(a) *Gas chromatograph*.—Equipped with flame ionization detector. (1) *Column*.—23% Carbowax 1500 (w/w) on Chromosorb W (60–80 mesh, acid-washed). Weigh 9 g Carbowax 1500 into 250 mL beaker and mix with H<sub>2</sub>O on steam bath. Weigh 30 g Chromosorb W in 250 mL beaker and combine with Carbowax soln in large flat-bottom Pyrex glass baking dish or flat-bottom polyethylene container (ca 20 × 25 cm). Add H<sub>2</sub>O to just cover solid support and mix thoroly. Evap. H<sub>2</sub>O with frequent stirring in hood. (Gentle steam may be applied to hasten evapn.) After evapn of H<sub>2</sub>O, heat coated support ca 2 hr in 100° oven.

Pack 2.4 m (8') × 1/4" od Cu tubing tightly and evenly by repeated tapping, and condition in column oven at 150° with He flow rate of 150 mL/min until steady baseline is observed at attenuation 1× at operating parameters (ca 24 hr).

(2) *Approximate parameters*.—Column temp. 70° (isothermal); detector and inlet temp. 150°; He carrier flow 150 mL/min.

Optimum operating conditions vary with column and instrument, and must be detd by using std solns. Adjust parameters for max. peak sharpness and optimum sepn. With high level std, *n*-PrOH should give almost complete baseline sepn from EtOH.

(b) *Syringe*.—10 μL, Hamilton Co. No. 701, or equiv.

### 9.076

#### Reagents

(a) *Isobutyl alcohol*.—see 9.066(b).

(b) *Isoamyl alcohol*.—See 9.066(c).

(c) *n*-Propyl alcohol.—Redistd, reagent grade.

(d) *Ethyl acetate*.—Redistd, reagent grade.

(e) *n*-Butyl alcohol.—Redistd, reagent grade.

(f) *n*-Butyl alcohol internal std solns.—(1) *High level*.—Dil. 10 mL *n*-BuOH to 100 mL with 40% alcohol. (1 mL added to 100 mL sample or std is equiv. to ca 81 g *n*-BuOH/100 L.) (2) *Low level*.—Dil. 1 mL *n*-BuOH to 200 mL with 95% alcohol. (1 mL added to 100 mL sample or std is equiv. to ca 4.1 g/100 L.)

(g) *n*-Propyl alcohol, isobutyl alcohol, isoamyl alcohol, and ethyl acetate high level std solns.—(1) *Stock soln*.—Accurately weigh 1 mL *n*-PrOH, 1 mL isobutyl alcohol, 2 mL isoamyl alcohol, and 1 mL EtOAc into 100 mL vol. flask and dil. to vol. with 40% alcohol. (2) *Intermediate soln*.—Dil. 10 mL stock soln to 200 mL with 40% alcohol. (3) *Working soln*.—(Approx. 40.2, 41.1, 81.2, and 45.1 g/100 L *n*-PrOH, isobutyl alcohol, isoamyl alcohol, and EtOAc, resp.) Dil. 5 mL stock soln to 100 mL with 40% alcohol. Add 1 mL high level *n*-BuOH internal std soln, (f)(1), and mix. Prep. fresh weekly.

(h) *n*-Propyl alcohol, isobutyl alcohol, isoamyl alcohol, and ethyl acetate low level working solns.—(Approx. 2.0, 2.1, 4.1, and 2.3 g/100 L *n*-PrOH, isobutyl alcohol, isoamyl alcohol, and EtOAc, resp.) Dil. 5 mL high level intermediate soln, (g)(2), to 100 mL with 95% alcohol. Add 1 mL low level internal std soln, (f)(2), and mix. Prep. fresh weekly.

Prep. std soln of ca same concn as sample if latter differs grossly from appropriate (high or low level) std.

### 9.077

#### Determination

Make preliminary injection of 10 μL sample to det. absence of *n*-BuOH. (If present, subtract its amt from total *n*-BuOH (original and internal std) content.) Add 1 mL internal std soln, (f) (high or low level, depending on higher alcohol and EtOAc

concn), to 100 mL sample in vol. flask, and chromatograph 10 μL aliquots of sample and std solns in triplicate.

Measure peak hts of *n*-PrOH, isobutyl alcohol, isoamyl alcohol, and EtOAc to nearest 0.05 cm and calc. peak ht ratio of each to *n*-BuOH (internal std) in sample and std solns. (For more accurate detn of isoamyl alcohol, use peak areas.)

$X = H \times S/H'$ , where  $X$  = concn of higher alcohol or EtOAc in sample (g/100 L);  $H$  = peak ht (or area for isoamyl alcohol) ratio of higher alcohol or EtOAc to *n*-BuOH in sample;  $H'$  = peak ht (or area for isoamyl alcohol) ratio of higher alcohol or EtOAc to *n*-BuOH in std;  $S$  = concn of higher alcohol or EtOAc in std (g/100 L).

Sum of isoamyl and isobutyl alcohol concns is ca equiv. to fusel oil concn as detd in 9.069–9.074.

## Alternative Method (17)

### 9.078

#### Apparatus

*Gas chromatograph*.—Equipped with flame ionization detector. (1) *Column*.—2% glycerol and 2% 1,2,6-hexanetriol (Aldrich Chemical Co.) (w/w) on Gas-Chrom R (100–120 mesh, non-acid-washed) (Applied Science Laboratories, Inc.). Weigh 0.2 g each of glycerol and 1,2,6-hexanetriol into 50 or 100 mL beaker and dissolve by stirring with MeOH. Weigh 9.6 g Gas-Chrom R in evapg dish (top diam. ca 100–125 mm), moisten with MeOH, and add soln of stationary phases. Mix thoroly, and gently heat mixt. on steam bath, stirring continuously. When material appears to be dry (light pink), continue heating and occasional stirring to ensure complete removal of solv. Store in capped jar. Pack 3 m (10') × 1/8" od Cu or stainless steel tube (0.030" wall; if steel is used, rinse inside several times with acetone to remove manufacturing oils, and air dry) with prepd support, using vibrator to ensure complete packing of column. Condition overnight in 80° column oven with He flow rate of 10–25 mL/min and detector end of column disconnected.

(2) *Approximate parameters*.—Column, injector, and detector temps (°)—80, 100, and 125, resp.; gas flows (mL/min)—He carrier and H<sub>2</sub> 25, air 250–400; attenuation 64×.

Optimum operating conditions vary with column and instrument and must be detd by using std solns. Adjust parameters for max. peak sharpness and optimum sepn. Analysis is complete in ca 11 min.

### 9.079

#### Reagents

(Use absolute alcohol thruout when alcohol is specified.)

(a) *n*-Propyl alcohol.—Reagent grade.

(b) *Isobutyl alcohol*.—(Fisher Scientific Co., Certified Reagent No. A-379.)

(c) *Amyl alcohol*.—(Gallard-Schlesinger Chemical Manufacturing Co., 584 Mineola Ave., Carle Place, NY 11514, AnalR No. 10038.) Mixt. of active-amyl and isoamyl alcohols, ca 22 and 78%, resp. Concn of 2 isomers varies from batch to batch. Det. composition of reagent by 9.080. Measure areas of 2 peaks by triangulation (ht × width at half-ht), and obtain concn of each by dividing area of each peak by sum of both peak areas.

(d) *3-Pentanol internal std soln*.—40.76 mg/mL (Aldrich Chemical Co., Inc., No. P802-5). Prep. soln contg 10 mL reagent in 200 mL alcohol-H<sub>2</sub>O (1+1).

(e) *Ethyl acetate*.—(Fisher Scientific Co., Certified Reagent No. E-145.)

(f) *n*-Propyl alcohol, isobutyl alcohol, and amyl alcohol std solns.—Prep. 3 or 4 std solns contg varying amts alcohols as follows: Into tared 100 mL vol. flasks contg alcohol-H<sub>2</sub>O (1+1), pipet fusel alcohols and weigh after addn of each component.

Proportions of fusel alcohols in each std soln should vary so that desired concn range of each is represented in random manner in series of std solns. Suggested amts: 0.25–1.5 mL *n*-PrOH, 1.0–2.5 mL isobutyl alcohol, and 2.0–5.0 mL amyl alcohol. Dil. each to vol. with alcohol-H<sub>2</sub>O (1+1).

(g) *n*-Propyl alcohol, isobutyl alcohol, and amyl alcohol working std solns.—Dil. 10 mL each std soln and 2.0 mL 3-pentanol internal std soln to 200 mL with alcohol-H<sub>2</sub>O (1+1) (1:20 diln).

(h) *Ethyl acetate std solns*.—Prep. 3 or 4 std solns contg 0–0.5 g/L (0–50 g/100 L) in H<sub>2</sub>O or alcohol-H<sub>2</sub>O (1+1). Use for prepg direct std curve by plotting peak ht (mm) against concn in g/100 L.

#### 9.080

#### Determination

Pipet 10 mL sample into convenient vessel (e.g., 1 oz French sq glass bottle with screw cap), add, by pipet (0.2 mL pipet graduated in 0.01 mL), 0.1 mL 3-pentanol internal std soln, and mix. Inject 2  $\mu$ L sample and working std solns. Measure peak ht of each component in working std soln and calc. peak ht ratio of each to internal std. Calc. concn ratio of each by dividing wt of component by that of internal std. (Proportion of active-amyl and isoamyl alcohols in mixt. must be taken into consideration in calcns of actual wts of each isomer in working std solns.)

Plot concn ratios (horizontal axis) against peak ht ratios (vertical axis) for each higher alcohol in all working stds to obtain family of curves. For EtOAc, plot peak ht directly against concn.

Similarly, measure peak ht of each component in sample and calc. peak ht ratios. Read concn ratios of all alcohols, using proper std curve. Multiply concn ratio of each fusel alcohol in sample by 40.76 to obtain g/100 L. New std curves need be prepd only when new instruments, parameters, or stds are used.

#### Furfural (18)—Official Final Action

#### 9.081

#### Reagent

*Furfural std soln*.—Redistil furfural thru short packed fractionating column at atm. pressure, and collect fraction boiling at 161.2° (uncorrected). Weigh 1 mL redistd furfural into 100 mL vol. flask and dil. to vol. with alcohol. Pipet 5 mL of this soln into 500 mL vol. flask and dil. to vol. with 50% alcohol (concn, ca 116 mg/L). Concd soln retains strength, but dil. soln does not.

#### 9.082

#### Determination

Pipet 25 mL distd spirits into volatile acid distn flask, Fig. 9:03, with  $\frac{1}{8}$  joints and steam distil until 200 mL collects. If haze is present in distillate, dil. with known vol. alcohol. Det. A at 277 nm.

Det. A of std solns of furfural contg 0, 1, 2, 3, 4, and 5 mg furfural/L. Plot std curve or calc. av. A of 1 mg furfural/L, A' (ca 0.15).

$$\text{mg Furfural/L} = (A/A') \times F,$$

where *F* is diln factor (vol. final soln on which *A* is detd/vol. sample).

#### Detection of Acetone, Other Ketones, Isopropanol, and Tertiary Butyl Alcohol Official Final Action

#### 9.083

#### Reagent

*Mercuric sulfate soln*.—Mix 5 g yellow HgO with 40 mL H<sub>2</sub>O and add, with stirring, 20 mL H<sub>2</sub>SO<sub>4</sub> and 40 mL H<sub>2</sub>O. Stir until completely dissolved. (Caution: See 51.079.)

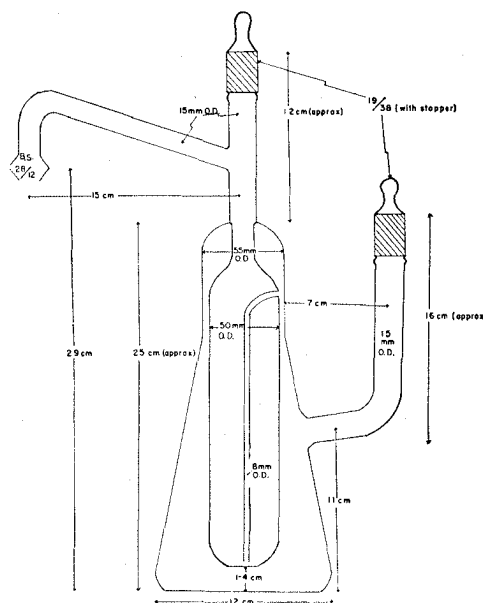

FIG. 9:03—Steam distillation flask

#### 9.084

#### Determination

To 2 mL distillate, 9.050, add 3 mL H<sub>2</sub>O and 10 mL HgSO<sub>4</sub> soln. Heat on boiling H<sub>2</sub>O bath 3 min. White or yellow ppt forming within 3 min indicates presence of acetone, other ketones, or *tert*-BuOH. Disregard any ppt forming after 3 min on boiling H<sub>2</sub>O bath.

If no ppt forms, test for isopropanol as follows: Place 8 g CrO<sub>3</sub> in 100 mL Kohlrausch flask, and add 15 mL H<sub>2</sub>O and 2 mL H<sub>2</sub>SO<sub>4</sub>. Connect flask with reflux condenser and add 5 mL sample very slowly thru condenser. Reflux 30 min; then cool and distil 2 mL, collecting distillate in 10 mL graduate. Add 3 mL H<sub>2</sub>O and 10 mL HgSO<sub>4</sub> soln, and proceed as above.

#### 9.085 Sugars—Official Final Action

See Chapter 31.

#### Methanol—Official Final Action

#### Chromotropic Acid Colorimetric Method (19)

#### 9.086

#### Reagents

(a) *Potassium permanganate soln*.—Dissolve 3.0 g KMnO<sub>4</sub> and 15.0 mL H<sub>3</sub>PO<sub>4</sub> in 100 mL H<sub>2</sub>O. Prep. monthly.

(b) *Sodium salt of chromotropic acid (sodium 1,8-dihydroxynaphthalene-3,6-disulfonate) soln*.—5% aq. soln. Filter if not clear. Prep. weekly. Either acid or salt may be used.

#### 9.087

#### Purification of Chromotropic Acid

If *A* of blank is >ca 0.05, purify reagent as follows:

Dissolve 10 g chromotropic acid or its salt in 25 mL H<sub>2</sub>O. (Add 2 mL H<sub>2</sub>SO<sub>4</sub> to aq. soln of salt to convert it to free acid.) Add 50 mL MeOH, heat just to bp, and filter. Add 100 mL isopropanol to ppt free chromotropic acid. (Add more isopropanol to increase yield of purified acid.)

#### 9.088

#### Preparation of Sample

Dil. or adjust sample to total alc. concn of 5–6%. Using 50 mL sample, distil thru simple still, collecting 40 mL distillate. Dil. to 50 mL with H<sub>2</sub>O. (If alcohol has been detd previously, distillate may be adjusted to 5–6% alc. concn and used for this test.) If

>0.05% MeOH by vol. is present, dil. to ca that concn with 5.5% alcohol. For samples contg <0.05% MeOH, measure 200 mL into efficient fractionating still, place system under total reflux 15 min, and then slowly distil at high rate of reflux ( $\geq 20:1$ ). Collect 10 mL distillate and dil. to 160 mL with H<sub>2</sub>O.

**9.089****Determination**

Pipet 2 mL KMnO<sub>4</sub> soln into 50 mL vol. flask. Chill in ice bath, add 1 mL chilled dild sample, and let stand 30 min in ice bath. Decolorize with little dry NaHSO<sub>3</sub> and add 1 mL chromotropic acid soln. Add 15 mL H<sub>2</sub>SO<sub>4</sub> slowly with swirling and place in hot (60–75°) H<sub>2</sub>O bath 15 min. Cool, add enough H<sub>2</sub>O to bring approx. to 50 mL mark, mix, and dil. to vol. with H<sub>2</sub>O at room temp. Read *A* at 575 nm against reagent blank of 5.5% alcohol treated similarly. Treat *std MeOH soln* contg 0.025% by vol. MeOH in 5.5% alcohol simultaneously in same manner, and read *A'*. (Temp. of std and sample should be within 1° since temp. affects *A*.)

$$\% \text{ MeOH in sample} = (A/A') \times 0.025 \times F,$$

where *F* = diln factor of sample.

*Example:* Sample was dild 25×; *A* of sample = 0.421; *A* of std MeOH = 0.368. Then  $(0.421/0.368) \times 0.025 \times 25 = 0.715\%$

(If color of sample is too intense, dil. with H<sub>2</sub>SO<sub>4</sub>-alcohol blank prepd as above. Not more than 3-fold diln is permitted, as ratio of chromotropic acid to HCHO is too low if diln is greater.)

**9.090 Immersion Refractometer Method (20)**

Det. Zeiss immersion refractometer reading at 17.5° of distillate obtained in detn of alcohol. If, on ref. to table, **9.03**, refractometer reading shows sp gr agreeing with that obtained in alcohol detn, **9.013**, it may be assumed that MeOH is absent. Low refractom-

eter reading indicates presence of appreciable amt of MeOH. If absence from the soln of refractive substances other than H<sub>2</sub>O and the alcohols is assured, this difference in refraction is conclusive evidence of presence of MeOH.

Addn of MeOH to alcohol decreases refractive index in direct proportion to amt added; hence, quant. calcn is made by interpolation in Table **9.03** of figures for pure alcohol and MeOH of same sp gr as sample.

*Example.*—Distillate has sp gr at 15.56° of 0.9625 and refractometer reading at 17.5° of 43.1. By interpolation in Table **9.03**, readings for alcohol and MeOH at this gravity are 65.2 and 31.7, resp., and difference is 33.5;  $65.2 - 43.1 = 22.1$ ;  $(22.1 \div 33.5) \times 100 = 66.0$ , showing 66.0% of total alcohol present is MeOH.

**Gas Chromatographic Method (21)****9.091****Apparatus**

See **9.075**.

**9.092****Reagents**

(a) *Alcohol*.—USP, MeOH-free.

(b) *Methanol stock soln*.—Dil. 10 mL MeOH, 99.9 mol % (Fisher Scientific Co., A-936, or equiv.) to 100 mL with 40% alcohol.

(c) *n-Butyl alcohol internal std stock soln*.—Dil. 10 mL *n*-BuOH, 99.9 mol % (Fisher Scientific Co., A-384, or equiv.) to 100 mL with 40% alcohol.

(d) *Methanol std soln*.—0.050% MeOH plus 0.030% *n*-BuOH internal std. Fill 100 mL vol. flask to ca 99 mL with 40% alcohol and add, by syringe, 500  $\mu$ L MeOH stock soln, (b), and 300  $\mu$ L *n*-BuOH stock soln, (c). Mix and dil. to vol. with 40% alcohol. Mix again.

**Table 9.03 Scale readings on Zeiss immersion refractometer at 17.5°, corresponding to specific gravities of ethyl and methyl alcohol solutions**

Sp. Gr. 15.56° 15.56°	Scale Readings			Sp. Gr. 15.56° 15.56°	Scale Readings

.9730	49.8	26.5	23.3				

Scale readings are applicable only to instruments calibrated in arbitrary scale units proposed by Pulfrich, *Z. angew. Chem.*, 1899, p. 1168. According to this scale, 14.5 = 1.33300, 50.0 = 1.34650, and 100.0 = 1.36464. If instrument used is calibrated in other arbitrary units, refractive index corresponding to observed reading can be converted into equivalent Zeiss reading by referring to **52.004**.

## 9.093

**Determination**

Inject 10  $\mu$ L MeOH std soln. Adjust operating parameters and attenuation to obtain measurable peak ht (ca  $\frac{1}{4}$  full scale deflection). Det. retention time of MeOH and *n*-BuOH (ca 3 and 12 min, resp.). Inject 10  $\mu$ L sample to est. MeOH, using attenuation if necessary, and to check for absence of *n*-BuOH. On basis of presence or absence of *n*-BuOH in sample, det. MeOH content from std curve prepd according to (a) or (b):

(a) *n*-Butyl alcohol absent.—On basis of est. of MeOH, prep. series of stds (4 or 5) in which range of concn includes MeOH concn in sample. Add internal std to both sample and std solns at concn similar to that of MeOH in sample. Calc. peak ht ratios of MeOH:*n*-butyl alcohol, using av. of duplicate injections, and plot ratios against MeOH concn.

(b) *n*-Butyl alcohol present.—Prep. series of MeOH stds as in (a), but do not add *n*-BuOH to sample or stds. Plot actual peak ht of MeOH against concn.

**Artificial Colors**

(See also 9.005–9.008)

9.094 **Marsh Test—Official First Action**

To 10 mL sample in 20 mL test tube add enough freshly shaken *Marsh reagent* (100 mL amyl alcohol, 3 mL  $\text{H}_3\text{PO}_4$ , and 3 mL  $\text{H}_2\text{O}$ ) to nearly fill tube, and shake several times. Let layers sep. Color in lower layer indicates that sample has been colored with caramel, synthetic dye, or extractive material from uncharred white oak chips.

In absence of any color, test 10 mL in same manner, using enough fusel oil, amyl alcohol, or Pentasol to nearly fill tube and shaking several times. Deeply colored lower layer indicates synthetic dye. Det. its identity as in Chapter 34. To confirm caramel apply one or more of following tests:

9.095 **Mathers Test—Official Final Action**

See 11.055.

9.096 ★ **Cyclohexanol Test—Official Final Action** ★

See 9.059, 10th ed.

9.097 **Coal-Tar Colors**

See Chapter 34.

**Tannin (22)—Official Final Action**

## 9.098

**Reagents**

(a) *Folin-Denis reagent*.—To 750 mL  $\text{H}_2\text{O}$  add 100 g  $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$ , 20 g phosphomolybdic acid, and 50 mL  $\text{H}_3\text{PO}_4$ . Reflux 2 hr, cool, and dil. to 1 L.

(b) *Sodium carbonate saturated soln*.—To each 100 mL  $\text{H}_2\text{O}$  add 35 g anhyd.  $\text{Na}_2\text{CO}_3$ , dissolve at 70–80°, and let cool overnight. Seed supersatd soln with crystal of  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ , and after crystn filter thru glass wool.

(c) *Tannic acid std soln*.—0.1 mg/mL. Dissolve 100 mg tannic acid in 1 L  $\text{H}_2\text{O}$ . Prep. fresh soln for each detn.

## 9.099

**Preparation of Standard Curve**

Pipet 0–10 mL aliquots std tannic acid soln into 100 mL vol. flasks contg 75 mL  $\text{H}_2\text{O}$ . Add 5 mL Folin-Denis reagent and 10

mL  $\text{Na}_2\text{CO}_3$  soln, and dil. to vol. with  $\text{H}_2\text{O}$ . Mix well and det. *A* after 30 min at 760 nm. Plot *A* against mg tannic acid/100 mL.

## 9.100

**Determination**

Using 1 mL sample, det. *A* as in 9.099 and obtain mg tannic acid/100 mL from std curve. If *A* is too great, repeat detn on 1+4 diln of sample. Samples treated as above may be compared in Nessler tubes against freshly prepd tannic acid stds treated in same manner.

**Cyanide (23)—Official First Action**

## 9.101

**Apparatus**

(Letters refer to Fig. 9:04.)

(a) *Distilling flask*.—500 mL, r-b, 3-neck with  $\frac{1}{8}$  joints, angle-type (Fisher Scientific Co., No. 10-165B, or equiv.) (A).

(b) *Thermometer*.—Range –10 to 110°, with  $\frac{1}{8}$  screw-cap adapter to fit one  $\frac{1}{8}$  side neck of distg flask (B).

(c) *Air inlet tube*.—With  $\frac{1}{8}$  cone to fit side neck of distg flask (C).

(d) *Condenser*.—Graham coil-type, with inner and outer  $\frac{1}{8}$  joints,  $\frac{1}{8}$  cone to fit center neck of distg flask (Fisher Scientific Co., No. 7-728B, 400 mm jacket length, or equiv.) (D).

(e) *Flange assembly*.—Consisting of 2 sep. ground-glass flanges at one end of sep. glass tubing, 7 mm diam. Lower tube (E) is ca 14 mm long and is also fitted with  $\frac{1}{8}$  cone to fit  $\frac{1}{8}$  socket at top of condenser;  $\frac{1}{8}$  cone has 2 glass hooks. Upper tube (F) is ca 5 mm long.

(f) *Clip*.—To connect 2 ground-glass flanges together (G).

(g) *Springs*.—To connect (D) and (F) securely together (H).

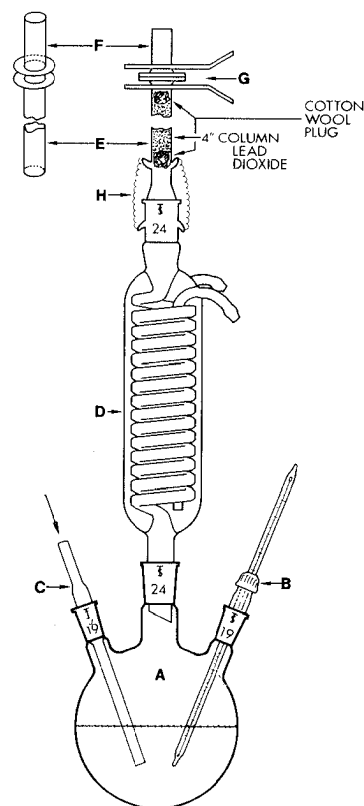

FIG. 9:04—Apparatus for determining hydrogen cyanide in distilled spirits.

★ Surplus method—see inside front cover.

## 9.102

## Reagents

(a) *Potassium ferrocyanide soln.*—(1) *Stock soln.*—0.01%  $K_4Fe(CN)_6 \cdot 3H_2O$  in 0.2%  $Na_2CO_3$ . Store in amber bottle.  $Na_2CO_3$  stabilizes this soln. (2) *Working soln.*—0.0001%  $K_4Fe(CN)_6 \cdot 3H_2O$ ; 27 mL equiv. to 10  $\mu g$  CN. Prep. fresh daily by dilg 1.0 mL stock soln to 100 mL with  $H_2O$ .

(b) *4,4'-Methylenebis(N,N-dimethylaniline)* (tetrabase).—Eastman Kodak Co., No. 244; or equiv.

(c) *Bis(ethyl acetoacetato) copper* (copper ethyl acetoacetate).—Fisher Scientific Co., No. 10057; or equiv.

(d) *Color reagent.*—Dissolve 50 mg tetrabase and 50 mg Cu Et acetoacetate in 10 mL  $CHCl_3$ . Store in closed bottle; prep. fresh weekly.

(e) *Test papers.*—Whatman No. 44 paper, or equiv., cut to size in strips to fit between flanges of ground-glass flange assembly. Impregnate with several drops color reagent immediately before use; let  $CHCl_3$  evap. completely before inserting test paper between flanges of assembly.

(f) *Lead dioxide.*—Dissolve ca 40 g  $Pb(OAc)_2$  in 200 mL  $H_2O$  by heating on  $H_2O$  bath in hood. Add  $NaOCl$  (13% available Cl) until there appears to be no further darkening in color (ca 100 mL). Ppt should be dark brown at this stage. Let stand ca 15 min. Filter thru double thickness Whatman No. 42 papers in buchner. Wash with  $H_2O$ , discard filtrate, and wash ppt with ca 200 mL  $HNO_3$  (1+9). Finally wash with  $H_2O$  and dry overnight in 105° oven.  $PbO_2$  produced by this method is granular and should be broken into pieces ca 20 mesh, but must not be ground any finer. Check each batch by applying control test for ferrocyanide std, 11.057(a), on 100 mL aliquots of  $H_2O$  contg 10  $\mu g$  CN and 500 ppm  $SO_2$  (as  $NaHSO_3$ ) and comparing stain produced with std stain. Anal. grade  $PbO_2$  is not suitable because it is too fine and prevents free flow of N to test papers.

## 9.103

## Distilled Spirits Free of Sulfur Dioxide

(For products contg  $SO_2$ , see 11.057.)

(a) *Control test.*—Add 27 mL  $K_4Fe(CN)_6 \cdot 3H_2O$  working soln (equiv. to 10  $\mu g$  CN) to 100 mL alcohol and 100 mL  $H_2O$  in 500 mL 3-neck flask with stopper in 1 side neck and gas inlet tube connected to N (or  $CO_2$ ) in other. (Use of gas to flush HCN thru test papers is preferred, but vac. may be used.) Connect center neck of flask to condenser and place ground-glass flange assembly in top of condenser; then connect hooks with springs. Insert test paper between 2 glass flanges and clip together. Remove stopper momentarily, add 10 mL  $H_2SO_4$  (1+9), and immediately replace stopper.

Assure rapid flow of cold  $H_2O$  thru condenser and then heat contents of flask just to bp. When boiling temp. is reached, pass N thru liq. at rate such that individual bubbles just cease to be visible as sep. bubbles, but form continuous stream. Check that all joints are tight. Let distn proceed 15 min; then remove test paper and examine for blue stain which indicates cyanide. (Alcohol vapors must not reach test paper.) Intense, well defined blue circle should be obtained with 10  $\mu g$  CN. Blank detn performed concurrently must show no color. (1  $\mu g$  CN, equiv. to 0.01 ppm CN in 100 mL sample, can be readily detected.)

(b) *Samples.*—Add 100 mL sample to 100 mL  $H_2O$  in 500 mL 3-neck distg flask, and test as in (a). For pos. results, confirm test papers showing faint or questionable stains by 2 addnl analyses. Blue stains are stable ca 1 week if kept out of direct light.

(c) *Confirmation.*—To confirm that pos. reactions from samples of unknown origin are due to CN, expose blue test paper to  $NH_3$  vapors. Colorless carbinol base is formed. With addn of HOAc, blue reappears.

## CORDIALS AND LIQUEURS

## 9.104 Physical Examination—Procedure

Note and record following: (a) Appearance, whether bright or turbid and presence of sediment; (b) color and depth of color; (c) odor; (d) taste.

## 9.105 Specific Gravity—Official Final Action

See 9.011.

## 9.106 Alcohol—Official Final Action

(a) *By weight.*—See 9.021.

(b) *By volume.*—See 9.013. Use pycnometer calibrated at 15.56°.

## Methanol—Official Final Action

## 9.107

## Preparation of Sample

Measure sample contg 20–25 mL absolute alcohol into distg flask, add enough  $H_2O$  to make total ca 100 mL, and distil, collecting ca 50 mL distillate. To distillate add 4 g NaCl for each 10 mL  $H_2O$  and let stand several hr for complete satn.

Transfer to separator, using ca 10 mL satd NaCl soln to wash out container, and shake with 25 mL pet ether. When sepn is complete, transfer aq. soln to second separator contg 25 mL pet ether; shake, and transfer aq. soln to third separator, also contg 25 mL pet ether; shake, and when sepn is complete, drain aq. soln into 200 mL distg flask. Meanwhile add 25 mL satd NaCl soln to first separator and follow sample thru with this soln, finally adding washings to sample soln in distg flask. Repeat this operation with second 25 mL portion satd NaCl soln, finally adding this also to distg flask. Distil mixt. into 50 mL vol. flask, using suitable adapter. After 48–49 mL distils, disconnect app., fill flask to mark with  $H_2O$ , mix, and det. MeOH as in 9.089 or 9.090.

## 9.108 Aldehydes—Official Final Action

Measure 100–200 mL sample into distn flask. If solid content is  $\leq 25$  g/100 mL, add 12.5–25 mL  $H_2O$ ; if  $> 25$  g/100 mL, add 5 mL  $H_2O$  for each 10 g solids present; distil slowly, collecting vol. distillate equal to that of sample, and proceed as in 9.052.

## 9.109 Fusel Oil—Official Final Action

Using 50 mL prepd distillate, 9.108, proceed as in 9.068, 9.071–9.074, or 9.077.

## 9.110 Total Solids—Official Final Action

(a) *From specific gravity of dealcoholized sample.*—Transfer residue from alcohol detn, 9.106(b), to original pycnometer with  $H_2O$ , dil. to mark with  $H_2O$  at 15.56°, and mix. Adjust temp. of pycnometer and contents to 20°; adjust meniscus to mark, using capillary tube or narrow strips of filter paper to remove any excess liq. while in 20° bath. Weigh, and calc. sp gr of liq. From 52.008 det. % dry substance and corresponding sp gr at 20°/4°.

Sp gr at 20°/4°  $\times$  % dry substance = total solids (g/100 mL).  
(b) *By evaporation.*—Fill 25 mL vol. flask with sample at 20°, and adjust meniscus, using capillary tube or narrow strips of filter paper, while flask is immersed in bath held at same temp. ca 30 min. Quant. transfer contents of flask to 100 mL vol. flask with  $H_2O$  and dil. to vol. with  $H_2O$  at convenient temp. At same temp., pipet 10 mL dild sample into dish contg sand and dry as in 31.008. Wt residue  $\times 40$  = total solids (g/100 mL).

(c) *From refractive index of dealcoholized sample.*—Restore residue from alcohol detn to original vol. by evapg or dilg as necessary. Det. refractometer reading of soln at 20° and obtain corresponding % dry substance. From 52.008 det. sp gr corresponding to % dry substance found and multiply by % dry substance to obtain g total solids/100 mL sample. To obtain % total solids, divide total solids/100 mL by sp gr, 9.011.

#### 9.111 ★ Glycerol—Official Final Action ★

By direct weighing, or by oxidn with  $K_2Cr_2O_7$  soln. See 9.111, 12th ed.

#### 9.112 Sucrose—Official Final Action

(a) *By polarization.*—Pipet, into evapg dish, vol. sample equiv. to 52 g as calcd from sp gr, 9.011, and exactly neutze with 1*N* NaOH, calcg amt required from acidity, 9.119. Evap. on steam bath to remove alcohol, transfer to 200 mL vol. flask, and proceed as in 31.025 or 31.026, beginning "... add necessary clarifying agent, ..." in 31.025(a).

(b) *By reducing sugars before and after inversion.*—Approximate sugar content of sample from total solids, 9.110, and pipet sample contg 5–7 g sugars into porcelain dish; exactly neutze with 1*N* NaOH soln, calcg amt required from acidity, 9.119, and evap. on steam bath to remove alcohol. Transfer to 200 mL vol. flask, clarify with neut.  $Pb(OAc)_2$  soln, 31.021(d), remove excess Pb with K oxalate, and proceed as in 31.031, using 31.038 for detn of reducing sugars.

#### 9.113 Ash—Official Final Action

Proceed as in 31.012 or 31.013, using 25 mL sample.

#### 9.114 Soluble and Insoluble Ash—Official Final Action

Using ash from 9.113, proceed as in 31.015.

#### 9.115 Alkalinity of Soluble Ash—Official Final Action

Using sol. ash from 9.114, proceed as in 31.016.

#### 9.116 Alkalinity of Insoluble Ash—Official Final Action

Using insol. ash from 9.114, proceed as in 31.017.

#### 9.117 Phosphorus—Official Final Action

Using ash obtained in 9.113, det.  $P_2O_5$  as in 11.034.

#### 9.118 Caramel—Official Final Action

See 11.055.

#### 9.119 Total Acidity—Official First Action

Place ca 600 mL  $H_2O$  in 800 mL beaker, add ca 1 mL phthln, and titr. to pink soln with 0.1*N* NaOH. Add 10–20 mL sample (unless this vol. gives soln such deep color that it will obscure end point, in which case 5 mL may be used) and titr. to pink comparable to that of soln before sample was added. Calc. acidity as g/100 mL sample in terms of predominating acid present in sample.

#### 9.120 Characteristic Acids—Preparation of Sample—Procedure

Use sample contg  $\leq 30$  g solids and  $\leq 200$  mg acid to be detd, as calcd from acidity; evap. to ca 30 mL and treat as in 9.121–9.124.

#### 9.121 ★ Tartaric Acid—Official Final Action ★

See 9.121, 12th ed.

#### 9.122 ★ Citric Acid—Official Final Action ★

See 9.122, 12th ed.

#### 9.123 ★ Total Malic Acid (Laevo and Inactive) ★ Official First Action

See 9.123, 12th ed.

#### 9.124 ★ Laevo-Malic Acid—Official First Action ★

See 9.124, 12th ed.

#### 9.125 Volatile Esters—Official Final Action

Measure 100–500 mL sample into distg flask and steam distil as in 12.026, collecting vol. distillate at least twice as great as vol. alcohol contained in sample. (If detn 9.126 is to be made, use 500 mL sample.) Disconnect app. and wash out condenser with little  $H_2O$ . Add ca 1 mL phthln, and titr. to pink that persists >1 min, using 0.1*N* NaOH or KOH. Add measured excess of 25–50 mL 0.1*N* alkali to soln, reflux 1 hr, cool, and titr. excess alkali with 0.1*N*  $H_2SO_4$ . Calc. number of mL 0.1*N* alkali used in saponification of esters as EtOAc. 1 mL 0.1*N* alkali = 8.8 mg EtOAc.

#### 9.126 ★ Gamma Undecalactone ★ (Qualitative Test) (24) Official Final Action

(Peach and apricot cordials)

See 9.087, 10th ed.

#### 9.127 ★ Optical-Crystallographic Properties ★ of Hydrazino- $\gamma$ -Undecalactone Official Final Action

See 9.088, 10th ed.

#### 9.128 Benzaldehyde—Official Final Action

See 19.100–19.101.

#### 9.129 Thujone (25)—Official First Action

To 500 mL sample add 1 mL *freshly distd aniline* and 1 mL  $H_3PO_4$ , and reflux 30 min on steam bath. Distil two 100 mL portions; reject first and test second for thujone as follows:

Add 0.5 g *semicarbazide hydrochloride* and 0.6 g anhyd. NaOAc (or 1.0 g crystd salt) and let mixt. stand overnight. Distil off alcohol at min. pressure. Steam distil to remove essential oils and other volatile material; collect and reject first ca 15 mL distillate. Wash down condenser with little alcohol and with  $H_2O$ . Cool sample, add 1 mL  $H_2SO_4$  (1+1), and again steam distil, collecting 20 mL distillate in cylinder. Pour distillate into small separator, and add 20 mL ether, using receiver as measure. Shake and sep. ether soln. Add 10 mL 65% alcohol and let ether evap. spontaneously. After all ether evaps, note odor of residue. Odor of thujone will be apparent if  $\geq 2$  mg is present in soln, provided it is not masked by presence of other odoriferous substances. Make modified Legal test as follows:

To soln obtained as above, add 1 mL 10%  $ZnSO_4$  soln and 0.25 mL *freshly prepd aq. Na nitroprusside soln* (0.1 g/mL). Slowly, with const stirring, add 2 mL 5% NaOH soln. Let stand 1–2 min. Add 1.5 mL HOAc and mix. Ppt of raspberry red color (resembling alcohol ppt of red fruit juice) shows presence of thujone. Neg. test is shown by similar ppt having appearance

★ Surplus method—see inside front cover.

similar to that of alcohol ppt from apple jelly or other light colored fruit.

# 10. Beverages: Malt Beverages and Brewing Materials\*

## BEER

(Unless otherwise directed, express results as % by wt.)

### 10.001 Preparation of Sample Official Final Action

Remove CO<sub>2</sub> by transferring sample to large flask and shaking, gently at first and then vigorously, keeping temp. of beer at 20–25°. If necessary, remove suspended material by passing the CO<sub>2</sub>-free beer thru dry filter paper.

## Color

### *Spectrophotometric Method (Standard Reference Color Method) (1)* Official Final Action

#### 10.002

#### Apparatus

*Spectrophotometer.*—Capable of isolating band width of  $\leq 1$  nm at 430 nm with wavelength and photometer scales checked and corrected for inaccuracies in accordance with instructions contained in NBS Letter Circular LC-1017 of Jan. 1967.

#### 10.003

#### Preparation of Sample

Partially degas sample by opening bottle at room temp., pouring contents into 1 L erlenmeyer, and swirling gently. Avoid formation of turbidity, and conduct partial degassing and readings as rapidly as possible.

#### 10.004

#### Determination

Place prepd sample in suitable cell and det. *A* at 430 nm and at 700 nm.

#### 10.005

#### Calculations

Calc. *A* from thickness at which read to  $\frac{1}{2}$ " (1.27 cm) (*A*<sub>1/2</sub>). If (*A*<sub>1/2</sub> at 430 nm)  $\times 0.039 > (A_{1/2}$  at 700 nm), sample is assumed "free of turbidity" and color is calcd as follows:

Beer color intensity =  $10 \times (A_{1/2}$  at 430 nm). If (*A*<sub>1/2</sub> at 700 nm)  $> 0.039 \times (A_{1/2}$  at 430 nm), clarify sample by centrifg or filtering, and redet. *A*.

Report color intensity values to nearest 0.1 unit.

### *Photometric Method—Official Final Action*

#### 10.006

#### Apparatus

Use any com. available filter photometer or abridged spectrophtr utilizing moderately broad spectral band and having adequate sensitivity. Use light filter with peak *T* in range 420–450 nm (blue-violet) for max. sensitivity and precision. (Filters for wavelengths in blue or blue-green range may also be used, but result in reduced precision.) Cell should be of such size, if possible, as to give *A* values between 0.187 and 0.699 (20–65% *T*), where max. precision is achieved. Use same size cell for both color measurement and calibration.

#### 10.007

#### Calibration of Photometers

*Beer calibration method.*—For each color intensity value for

which measurements are to be made, obtain 6–8 replicate bottles of beer which are low in air content and have been pasteurized.

Det. color intensity value of the beer by averaging readings obtained for  $\geq 2$  bottles by *Standard Reference Color (SRC) Method*, 10.004. If these values must be obtained from another laboratory, ship bottles of beer by the fastest available method, marked to avoid rough handling.

Det. photometer reading of the beer by averaging readings obtained for  $\geq 2$  bottles with wavelength and cell as in 10.006. Calc. calibration factor in accordance with photometer instructions or prep. calibration curve by plotting *A* or photometer scale reading against the *SRC* value for sample, assuming that curve passes thru origin. This calibration will be accurate only for readings in immediate vicinity of calibration point. If it is desired to accurately measure color intensity of  $> 1$  sample or colors over range of values, calibrate photometer for each sample or use beers having colors which cover desired range. Calc. av. calibration factor or prep. av. calibration curve.

#### 10.008

#### Preparation of Sample

See 10.003.

#### 10.009

#### Determination

Place sample in cell and det. photometer reading. Calc. color intensity value, using calibration factor or calibration curve. Report color to nearest 0.1 unit.

### Total Haze after Chilling (2)—Official Final Action

#### 10.010

#### Reagents

(Use turbidity-free distd H<sub>2</sub>O thruout.)

(a) *Hydrazine sulfate soln.*—1%. Dissolve 1.000 g H<sub>4</sub>N<sub>2</sub>.H<sub>2</sub>SO<sub>4</sub> in H<sub>2</sub>O (may require 4–6 hr) and dil. to 100 mL.

(b) *Stock formazin suspension.*—Dissolve 2.500 g hexamethylenetetramine (formin) in 25 mL H<sub>2</sub>O in 125 mL erlenmeyer, pipet in 25 mL 1% hydrazine sulfate soln, and stopper flask. Formazin begins to ppt in 6–8 hr and pptn is complete within 24 hr. Prep. every 3 months.

(c) *1000 Turbidity std.*—Dil. 14.5 mL well mixed stock suspension, (b), to 1 L with H<sub>2</sub>O in vol. flask. Prep. weekly. (1000 formazin turbidity units (FTU) on empirical formazin turbidity scale represents reflectance of insol. reaction products of 0.0725 g hydrazine sulfate with 0.7250 g hexamethylenetetramine dild to 1 L.)

(d) *Working stds for visual method.*—Prep. suitable dilns, daily, of 1000 turbidity std with H<sub>2</sub>O. FTU stds  $< 100$  are suitable for fresh beers; higher stds may be required for older samples. Use increments of 10 FTU for stds  $< 100$  FTU; in 20 FTU increments for 100–200; and in 50 FTU increments for  $> 200$  FTU.

### Visual Method

#### 10.011

#### Apparatus

(a) *Clark Turbidimeter, Model CLT.*—Code 648. Available from Cargille Scientific Inc., 55 Commerce Rd, Cedar Grove, NJ 07009.

\* Many methods in this chapter have been tested by both American Society of Brewing Chemists and Association of Official Analytical Chemists and have been adopted by both Associations. See "Methods of Analysis, A.S.B.C.," 7th rev. ed., 1976.

Viewing box of same dimensions and lighting is also suitable.

(b) *Red Plexiglas sheet*.— $\frac{1}{4}$ " thick, ca 1 sq ft (930 sq cm).

(c) *Constant temperature bath*.— $0 \pm 0.2^\circ$ .

(d) *Ice-water bath*.—Contg few drops wetting agent.

(e) *Flint glass bottles*.—Of same dimensions as flint glass bottles contg beer test samples; or clear drinking glasses (shells), 10 oz (300 mL), od ca 66 mm at bottom and 67 mm at top.

#### 10.012

#### Determination

(Make comparisons with samples at  $0^\circ$ . Keep test samples in  $0^\circ$  bath when not matching turbidities.)

Place container of beer to be tested in upright position in  $0^\circ$  bath and hold 24 hr.

Prep. series of formazin turbidity working stds covering range of expected turbidities of test samples. Fill into flint glass bottles of same dimensions as those holding beer test samples.

If beer is in flint glass bottles, carefully remove bottle from const temp. bath without disturbing sediment. Dip bottle into ice- $H_2O$  bath contg few drops wetting agent to prevent fogging or accumulation of  $H_2O$  droplets on bottle while in viewing box. Place bottle of beer in viewing box between 2 bottles of formazin turbidity working stds. Compare turbidities by viewing thru red Plexiglas sheet placed 5 cm (2") in front of bottles. Change formazin stds until that working std is found which most closely matches turbidity of test sample.

If beer is not in flint glass bottles, carefully remove container from const temp. bath and, without disturbing sediment, pour beer into clear 10 oz drinking glass (shell) which has been prechilled by standing (external contact only) in ice- $H_2O$  bath contg wetting agent. Degassing is not necessary. Use formazin turbidity working stds in identical 10 oz glasses to match turbidities as above for bottles.

Report as total haze of the beer after chilling, formazin turbidity units (FTU) of working std giving closest match. In range 0–100 FTU, report to nearest 10 FTU; 100–200, 20; >200, 50.

#### Nephelometric Method

#### 10.013

#### Calibration

*Nephelometer*.—Prep. calibration curve at 580 nm or other suitable wavelength for instrument employed by use of series of working stds or dilns of 1000 turbidity std. If readout device of nephelometer is 0–100 scale of arbitrary units, set needle to indicate 0 units when cell is filled with turbidity-free distd  $H_2O$  and 100 units when it is filled with selected formazin turbidity std.

#### 10.014

#### Determination

Place containers of beer to be tested in upright position in  $0^\circ$  bath and hold 24 hr.

Prechill nephelometer cell in small ice- $H_2O$  bath contg wetting agent (external contact only). Carefully remove container of beer from bath and, without disturbing sediment, rinse and fill cell with test sample. Place cell in ice- $H_2O$  bath contg wetting agent, and degas beer by stirring with thermometer. When beer temp. is  $0^\circ$ , place cell in sample chamber of nephelometer and det. reading. (Beer must be at  $0^\circ$  when taking reading.)

#### 10.015

#### Calculations

Calc. FTU total haze from calibration curve or by formula:  $FTU = R \times S/100$ , where  $R$  = nephelometer (galvanometer scale) reading;  $S$  = FTU of formazin turbidity std used for calibration of nephelometer.

#### 10.016 Specific Gravity—Official Final Action

Det. sp gr of prepd sample, **10.001**, at  $20/20^\circ$  (in air) as in **9.011**, but use pycnometers described in **10.106(i)** and **10.107(b)** or (c).

#### Viscosity of Beer (3)—Official Final Action

#### 10.017

#### Apparatus

(a) *Constant temperature bath*.—Adjusted to  $20.00 \pm 0.05^\circ$ .

(b) *Viscometer*.—Ostwald or Cannon-Fenske;  $H_2O$  time range 50–150 sec.

#### 10.018

#### Determination

Prep. sample as in **10.001**, ensuring complete decarbonation but avoiding loss of surface active components. Det. sp. gr. as in **10.016**.

Clean viscometer with chromic acid cleaning soln, rinse with  $H_2O$ , and drain. Temperate viscometer,  $H_2O$ , and beer to  $20^\circ$  in  $H_2O$  bath. Add appropriate vol.  $H_2O$  (usually 5 or 10 mL) at  $20^\circ$  to viscometer. Using suction, draw  $H_2O$  above upper mark. Let liq. level fall, and start timing with stopwatch as meniscus passes upper mark. Stop timing when meniscus passes lower mark.

Rinse viscometer with beer sample, and det. time required for passage of beer between menisci as above.

#### 10.019

#### Calculations

(a) *Absolute or dynamic viscosity (Centipoise)*.—(1)

Viscosity (cP) = flow time of beer at  $20^\circ \times$  sp gr of beer  $\times 1.002/\text{flow time of } H_2O \text{ at } 20^\circ$ ,

where 1.002 = viscosity of  $H_2O$  in cP at  $20^\circ$ . Report to second decimal place.

(2) *Example*.—Flow time of  $H_2O$  = 89.8 sec; flow time of beer = 130.2 sec; sp gr of beer = 1.03425;

Viscosity, cP =  $130.2 \times 1.03425 \times 1.002/89.8 = 1.503 = 1.50$  cP

(b) *Kinematic viscosity (Centistoke)*.—(1)

Viscosity (cS) = flow time of beer at  $20^\circ \times 1.0038/\text{flow time of } H_2O \text{ at } 20^\circ$ ,

where 1.0038 is viscosity of  $H_2O$  at  $20^\circ$  in cS. Report to second decimal place.

(2) *Example*.—Flow time of  $H_2O$  = 89.8 sec; flow time of beer = 130.2 sec;

Viscosity, cS =  $130.2 \times 1.0038/89.8 = 1.455 = 1.46$  cS

(c) *SI system*.—(1) SI unit for dynamic viscosity is Pascal-second (Pa·sec). 1 cP = 0.001 Pa·sec = 1 mPa·sec.

*Example*.—1.503 cP = 0.001503 Pa·sec, or 1.503 millipascal-sec, or 1.50 mPa·sec.

(2) SI unit for kinetic viscosity is meter<sup>2</sup>/second (m<sup>2</sup>/sec). 1 cS = 0.000001 m<sup>2</sup>/sec = 1  $\mu^2$ /sec.

#### 10.020 Apparent Extract—Official Final Action

Find apparent ext corresponding to sp gr detd at  $20/20^\circ$  from **52.009**, reporting to second decimal place.

#### 10.021 Real Extract—Official Final Action

(a) Evap. 75–100 mL sample (accurately weighed to 0.1 g) on  $H_2O$  bath or asbestos plate, at temp.  $\leq 80^\circ$ , to ca  $\frac{1}{3}$  original vol. Cool, dil. to original wt with  $H_2O$ , and det. sp gr with pycnometer at  $20/20^\circ$ . Det. real ext directly from **52.009**.

(b) If no antifoam material was used in detn of alcohol, **10.023**, quant. transfer residue with hot  $H_2O$  to 100 mL vol. flask. Cool, and dil. to 100 mL at  $20^\circ$ . Det. sp gr at  $20/20^\circ$ , **10.016**, and find

ext directly from 52.009. If 100 mL beer was taken, correct as follows:

$$\text{Ext found} \times \text{sp gr of dealcoholized beer} \\ / \text{sp gr of beer} = \text{g ext}/100 \text{ g beer.}$$

#### 10.022 Extract of Original Wort—Official Final Action

Calc. from following formula and report to first decimal place:

$$O = [(P \times 2.0665) + E] \times 100/[100 + (P \times 1.0665)],$$

where  $O$  = ext of original wort;  $P$  = % alcohol by wt (g/100 g beer); and  $E$  = % real ext, 10.021(a) or (b).

#### 10.023 Alcohol by Volume—Official Final Action

See 11.005, but use pycnometers described in 10.106(i) and 10.107(b) or (c).

#### Alcohol by Weight

#### 10.024 Specific Gravity Method—Official Final Action

See 9.021, but use pycnometers described in 10.106(i) and 10.107(b) or (c).

#### Refractometer Method (4) Official Final Action

#### 10.025

#### Apparatus

(a) *Immersion refractometer*.—Bausch & Lomb, Carl Zeiss, Inc., 444 Fifth Ave, New York, NY 10018, or equiv., with prisms covering range 1.32–1.37  $n$ .

(b) *Water bath*.—See 10.106(k).

(c) *Pycnometer*.—See 10.106(i) and 10.107(b) or (c).

#### 10.026

#### Calibration

Adjust refractometer light to give max. contrast between light and dark fields. Adjust color compensator and focus for sharp, color-free dividing line.  $H_2O$ , double-distd from glass, should read ca 14.50 at 20°. Read  $H_2O$  before each sample series. Rinse prism with  $H_2O$  after each sample and dry with soft tissue.

Prep. calibration curve to convert refractometer readings and sp gr detns to % alcohol by wt by analyzing beers covering alcohol range of interest by 10.024 and 10.027. Plot results, using ordinates ( $R - N$ ), where  $R$  = refractometer reading ( $R_{\text{beer}} - R_{\text{water}}$ ),  $N = 1000 \times (\text{sp gr} - 1.00000)$ , and abscissa = % alcohol by wt, 10.024. Fit least squares line to adequate number of points to get accuracy desired. Det. equation of line and slope. (See Definitions of Terms and Explanatory Notes, Item (24).) Calc. % alcohol by wt by formula or read from calibration curve. % alcohol by wt =  $F \times (R - N) + C$ , where  $F$  = slope of calibration line, and  $C$  = const of calibration curve equation.

#### 10.027

#### Determination

Det. sp gr of decarbonated beer by 10.016. Place refractometer cuvet contg distd  $H_2O$  and clear decarbonated beer samples in 20°  $H_2O$  bath. Place prism of refractometer in  $H_2O$  cuvet and check temp. after 15 min. Make 5 readings to nearest 0.1 scale division and average results ( $R_{\text{water}}$ ). Transfer dry prism to beer sample cuvet, wait  $\geq 1$  min, make 5 readings to nearest 0.1 scale division, and average results ( $R_{\text{beer}}$ ). Calc. % alcohol by wt by formula or read from calibration curve.

#### 10.028 Real Degree of Fermentation or Real Attenuation—Official Final Action

Calc. as follows and report to first decimal place:

$$(\text{orig. ext} - \text{real ext}) \times 100/\text{orig. ext.}$$

#### 10.029 Apparent Degree of Fermentation or Apparent Attenuation—Official Final Action

Calc. as follows and report to first decimal place:

$$(\text{orig. ext} - \text{apparent ext}) \times 100/\text{orig. ext.}$$

#### 10.030 End Fermentation (Yeast Fermentable Extract) (Fermentable Sugars)—Official Final Action

Det. real ext, 10.021, or apparent ext, 10.020. Ferment 250 mL beer with 1 g active compressed brewers yeast 24–48 hr at 15–25°, or until fermentation is complete, providing fermentation flask with  $H_2O$  or Hg seal. Filter; det. real ext, 10.021, or apparent ext, 10.020. Fermentable sugars = difference in real ext before and after fermentation; or fermentable sugars =  $0.82 \times$  difference in apparent ext before and after fermentation.

#### 10.031 Caloric Content—Official First Action

Det. sp gr (= density), 10.016, % alcohol by wt, 10.024 or 10.027, real ext, 10.021, and ash, 10.047, of beer sample.

$$\text{Calories}/100 \text{ g} = (\text{g real ext} - \% \text{ ash}) \times 4 \\ + (\% \text{ EtOH by wt} \times 6.9);$$

$$\text{Calories in vol.} = (\text{Calories}/100\text{g}) \times (\text{beer vol.}_{20^\circ} \times \text{density})/100,$$

where vol. is expressed in units required by test.

#### 10.032 ★ Glycerol—Official Final Action ★

Dichromate oxdn method. See 11.010(b), 12th ed.

#### Total Acidity (5)—Official Final Action

#### 10.033 Indicator Titration Method

Bring 250 mL  $H_2O$  to bp and continue boiling 2 min. From fast-flowing pipet add 25 mL beer previously decarbonated by shaking and filtering, 10.001. After emptying pipet, continue heating 60 sec, regulating heat so that soln resumes boiling during final 30 sec. Remove from heat, stir 5 sec, and cool rapidly to room temp.

Add 0.5 mL 0.5% phthln. Titr. with 0.1N NaOH against white background. Make frequent color comparisons with sample of equal vol. and diln to which has been added approx. anticipated amt of alkali but no indicator. Titr. to first appearance of faint pink. Read buret. Add 0.2 mL more alkali; color should then be permanent, definite pinkish red, indicative of overtitrn. Take first buret reading as end point.

Observe strictly all details of method. However, 100 mL  $H_2O$ , 10 mL beer, and 0.2 mL indicator may be used in place of amts specified above. (Use potentiometric titrn method, 10.034, for beers of dark color which, even when dild, may not permit judging phthln end point with necessary precision.)

Report results: (a) as lactic acid, to nearest 0.01% (1 mL 0.1N alkali = 0.0090 g lactic acid); or (b) as mL 1N alkali, to nearest 0.1 mL, necessary for neutzn of 100 g beer.

#### 10.034 Potentiometric Titration Method

Use glass-calomel electrode system. Decarbonate beer completely by shaking, 10.001. Using 50 mL undild sample (or such amt as best suits titrn assembly), titr. potentiometrically with 0.1N NaOH to pH 8.2. Add alkali in 1.5 mL portions to ca pH 7.6, and in 0.15 mL portions from there to pH 8.2. Make sure that complete equilibrium and good convergence are attained before reading buret at exactly pH 8.2. Report results as in 10.033.

★ Surplus method—see inside front cover.

**Precautions:** Observe all details of good potentiometric technique, including following: Stdze potentiometer against fresh 0.05M K acid phthalate, 50.007(c), before and after any set of titrns; read potentiometer to nearest 0.02 unit; use flexible shielding around electrode leads and motor cords; ground motor and motor cords, preferably to H<sub>2</sub>O pipes; avoid contact between electrodes and glass beaker; use proper stirring speed to ensure quick mixing but to avoid foaming which may temporarily trap some of alkali added; stop titrn at  $\leq$ pH 8.6 to minimize alkali contamination of glass electrode; check batteries frequently. Follow manufacturer's instructions for potentiometer used.

#### Hydrogen-Ion Activity (pH) Official Final Action

##### 10.035 Potentiometric Method

Det. pH of undild sample, 10.001, using glass-calomel electrode system. Follow manufacturer's instructions for potentiometer used. Check pH meter before and after use against std K acid phthalate buffer, 50.007(c). Observe precautions in 10.034. Report results to nearest 0.05 pH.

##### 10.036 Volatile Acids—Official Final Action

Using 100 mL beer, proceed as in 11.040. Express result as HOAc, g/100 mL. 1 mL 0.1N alkali = 0.0060 g HOAc.

##### 10.037 Carbohydrate Content—Official First Action

Det. sp gr (=density), 10.016, real ext, 10.021, ash, 10.047, and protein, 10.045, of beer sample.

g Carbohydrate/100 g

$$= (\text{g real ext}/100\text{g}) - (\% \text{ protein} + \% \text{ ash})$$

g Carbohydrate in vol.

$$= (\text{g carbohydrate}/100 \text{ g}) \times (\text{beer vol.}_{20^\circ} \times \text{density})/100,$$

where vol. is expressed in units required by test.

##### 10.038 Reducing Sugars—Official Final Action

Dil. 25 mL prepd sample, 10.001, measured at 20°, to 100 mL with H<sub>2</sub>O at same temp. Det. reducing sugars in 25 mL of this soln by Munson-Walker method, 31.060, or dil. 50 mL beer with H<sub>2</sub>O to 100 mL and use Lane-Eynon method, 31.059. Express result as g maltose/100 mL beer. For conversion to % by wt, divide results by sp gr of beer.

##### 10.039 Dextrin—Official Final Action

To 25 mL prepd sample, 10.001, measured at 20° in 500 mL boiling flask, add 15 mL HCl (sp gr 1.125) and dil. to 200 mL. Attach flask to reflux condenser, and keep in boiling H<sub>2</sub>O bath 2 hr. Cool, nearly neutze with NaOH soln (1+1), dil. to 250 mL in vol. flask, filter, and det. glucose as in 31.051.

$$\text{g Dextrin}/100 \text{ mL beer} = [\text{glucose (g}/100 \text{ mL}) - (1.053 \times \text{maltose, 10.038})] \times 0.9.$$

#### Diacetyl (6)—Official Final Action ASBC Colorimetric Method

##### 10.040

##### Apparatus

(a) *Compressed carbon dioxide gas.*—In steel cylinder with reducing valve connected thru 1-hole rubber stopper into 1 neck of boiling flask, (b), ending high up in flask.

(b) *Glass distillation apparatus.*—With following parts: boiling flask, 2-neck, 500 mL; distg tube, mounted vertically on boiling flask; condenser, H<sub>2</sub>O-cooled, connected by 75° adapter, if necessary, to distg tube so that condenser slopes downward;

curved, tapered tube adapter, connected to condenser delivery tip to dip below liq. level in receiver; and receiver, such as 50 mL beaker, marked at 15 and 35 mL.

(c) *Heating mantle.*—For boiling flask, (b), or burner.

(d) *Spectrophotometer or colorimeter.*—Capable of measuring A at 520 nm; with matched 1 cm cells.

##### 10.041

##### Reagents

(a) *Dimethylglyoxime std soln.*—0.0674 mg/mL. Dissolve 0.1348 g dimethylglyoxime in 3–5 mL alcohol, dil. to 2 L with H<sub>2</sub>O, and mix well.

(b) *Dipotassium hydrogen phosphate in aqueous acetone soln.*—0.827M. Dissolve 14.4 g K<sub>2</sub>HPO<sub>4</sub> (or 19.9 g K<sub>2</sub>HPO<sub>4</sub>·3H<sub>2</sub>O) in H<sub>2</sub>O, add 20 mL acetone, dil. to 100 mL with H<sub>2</sub>O, and mix well. Store in refrigerator.

(c) *Ferrous sulfate soln.*—5%. Dissolve 5 g FeSO<sub>4</sub>·7H<sub>2</sub>O in 100 mL H<sub>2</sub>SO<sub>4</sub> (1+99), and mix well. Discard when soln turns yellow due to oxidn of Fe.

(d) *Hydroxylamine hydrochloride soln.*—6% aq. soln of NH<sub>2</sub>OH·HCl.

(e) *Potassium dihydrogen phosphate alkaline soln.*—0.30M. Dissolve 1.0 g KH<sub>2</sub>PO<sub>4</sub> in 25 mL 0.1N NaOH, and mix well.

(f) *Potassium sodium tartrate, saturated soln.*—Shake 90 g K Na tartrate well with 50 mL H<sub>2</sub>O, and let settle.

(g) *Silicone antifoam.*—Dow Corning Antifoam A, or equiv.

##### 10.042

##### Preparation of Standard Curve

In 20 mL vol. flasks, prep. series of dimethylglyoxime std solns contg, in increments of 0.025 mg, 0.025–0.200 mg diacetyl by mixing appropriate vols dimethylglyoxime std soln, (a) (0.741 × mg dimethylglyoxime/mL = mg diacetyl/mL), with 0.75 mL 6% NH<sub>2</sub>OH·HCl soln and sufficient H<sub>2</sub>O to yield 15 mL. Heat each soln 15 min in ca 80° H<sub>2</sub>O bath, cool to room temp., add 1.0 mL 0.827M K<sub>2</sub>HPO<sub>4</sub>, and let stand 5 min. Successively add 0.6 mL NH<sub>4</sub>OH, 2.5 mL satd K Na tartrate soln, and 0.2 mL 5% FeSO<sub>4</sub> soln. Dil. to 20 mL with H<sub>2</sub>O, and mix by inversion.

Prep. blank contg all reagents, except dimethylglyoxime, in sufficient H<sub>2</sub>O to yield 20 mL.

Set spectrophtr to read 0.4 at 520 nm with blank in cell. Obtain A readings at 520 nm for dimethylglyoxime std solns contg 0.025–0.200 mg diacetyl equiv. Plot A at 520 nm against mg diacetyl/20 mL. Std curve should be straight line passing thru origin.

##### 10.043

##### Determination

Place 25 mL 0.30M KH<sub>2</sub>PO<sub>4</sub> in 500 mL boiling flask. Add 250 mL cold beer, not decarbonated, and 1 drop antifoam. Fit 1 neck of boiling flask to lower joint of vertical distg tube of distn app. Place tip of adapter into 0.75 mL 6% NH<sub>2</sub>OH·HCl soln and 2–3 mL H<sub>2</sub>O to seal adapter. Cool receiver during distn. If sample is expected to have high diacetyl concn, e.g., if diacetyl can be smelled or tasted readily, use 1.50 mL NH<sub>2</sub>OH·HCl soln and divide distillate into 2 equal portions. Use only 1 portion for distn, and multiply result by 2.

Connect CO<sub>2</sub> line to feed into boiling flask well above liq. level, and adjust CO<sub>2</sub> gas flow to maintain CO<sub>2</sub> atm. in entire system. Heat, and distil at ca 1 drop/sec. Collect 30 mL distillate.

Place receiver in ca 80° H<sub>2</sub>O bath 15 min. Raise temp. of H<sub>2</sub>O bath to 100° or transfer receiver to boiling H<sub>2</sub>O bath. Let distillate evap. to 15 mL. Cool to room temp., and transfer quant. to 20 mL vol. flask.

Add 1.0 mL 0.827M K<sub>2</sub>HPO<sub>4</sub> and let stand 5 min. Successively add 0.6 mL NH<sub>4</sub>OH, 2.5 mL satd K Na tartrate soln, and 0.2 mL FeSO<sub>4</sub> soln. Dil. to 20 mL with H<sub>2</sub>O and mix. Within 20 min, read A of colored soln at 520 nm against blank.

From calibration curve, det. mg diacetyl in 250 mL sample. Multiply by 4 to obtain mg diacetyl/L beer. Report result to 2 decimal places.

#### 10.044 Iodine Reaction for Unconverted Starch—Procedure

(a) *For light beer.*—Fill 15 mm diam. test tube to within 2.5 cm from rim with beer, **10.001**. Carefully add 0.02*N* I from dropper to form distinct layer on top of beer. Observe at once, by transmitted light, color developed at interface. Report blue as indicating presence of starch; purple, amyloextrin; and reddish tinge, erythrodextrin. Qualify results by using terms faint trace, trace, and plain trace according to whether the color developed is faint, distinct, or strong.

(b) *For dark beer, but applicable also to a light beer.*—To 5 mL beer in test tube add 25 mL alcohol, shake thoroly, and let stand. Decant, pouring off last trace of beer-alcohol mixt. Dissolve ppt (dextrin) in 5 mL H<sub>2</sub>O and to this soln add 0.02*N* I soln dropwise. Interpret as in (a).

#### 10.045 Protein—Official Final Action

To 25 mL prepd sample, **10.001**, at 20° in Kjeldahl flask, add 2–3 mL H<sub>2</sub>SO<sub>4</sub> and conc. to sirupy consistency. Det N as in **2.057**. %N × 6.25 = % protein.

$$\% \text{ protein} = \frac{[(\text{mL } 0.1\text{N acid} - \text{mL } 0.1\text{N base}) \times 1.4 \times 6.25 \times 100]}{(\text{sp gr} \times \text{mL sample} \times 1000)}$$

#### 10.046 Free Amino Nitrogen in Beer (26) Official Final Action

Prep. sample as in **10.001**. Dil. 1.0 mL prepd sample to 50 mL with H<sub>2</sub>O. Transfer 2.0 mL to each of three 16 × 150 mm test tubes and proceed as in **10.180**.

#### 10.047 Ash—Official Final Action

Evap. to dryness 50 mL prepd sample, **10.001**, measured at 20°. Proceed as in **31.012** or **31.013**.

#### 10.048 Phosphorus—Official Final Action

To 50 mL prepd sample, **10.001**, measured at 20°, add 20 mL 2% Ca(OAc)<sub>2</sub> soln, evap. to dryness, and ignite at low redness to white ash. Add 10–15 mL boiling HNO<sub>3</sub> (1+9) and det. P<sub>2</sub>O<sub>5</sub> as in **7.119**. (Washing phosphomolybdate ppt with 1% KNO<sub>3</sub> soln instead of H<sub>2</sub>O prevents creeping.)

#### Carbon Dioxide—Official Final Action Manometric Method (7)

##### 10.049

##### Apparatus

(a) *Piercing apparatus*—(1) *For bottles.*—Consists of gas-tight packing box and fastening for adjustment over container, and hollow spike connected to accurate pressure gage and outlet valve. Check gages frequently. (2) *For cans.*—Consists of metal frame in which can is placed. Top of app., which is pressed or screwed down and locked over can top, contains hollow spike surrounded by compressible rubber sealing plug; hollow spike leads to accurate pressure gage and outlet valve. (One app., adjustable for use with both bottles and cans, may be employed.)

*Notes:* Piercing devices can be obtained from Zahm and Nagel Co., Inc., 74 Jewett Ave, Buffalo, NY 14214; and Micromat, 185 Rt 17, North Mahwah, NJ 07430.

For suitable manometer for calibrating gages, see Gray and Stone, Ind. Eng. Chem., Anal. Ed., **10**, 15 (1938). Dead wt testing unit suitable for calibration can be obtained from AMETEK/Mansfield & Green Division, 6185 Cochran Rd, Solon, OH 44139;

Amthor Testing Instrument Co., Inc., 45–53 Van Sinderen Ave., Brooklyn, NY 11207; Dresser Industries, Inc., 250 E Main St, Stratford, CT 06497, and other companies.

(b) *Absorption buret.*—(Fig. **10.01**). Consists of graduated tube (one type has 0–5 mL graduated in 0.05 mL divisions, 5–15 mL in 0.1 mL, and 15–25 mL in 0.5 mL) with bulb marked at 40 mL, and closed at each end by stopcocks. Connect buret to valve of piercing app. and to leveling bulb by transparent alkali-resistant plastic or rubber tubing. (Burets are available from Zahm and Nagel Co. and Micromat Co., (a), and from New York Laboratory Supply Co.)

(c) *Leveling bulb.*—Approx. 300 mL, with support.

#### 10.050

#### Determination

Bring samples to 25° by immersion in H<sub>2</sub>O bath at 25°. If sample is bottle, make scratch on bottle at beer level. If sample is can, weigh unopened can.

Fill leveling bulb and then absorption buret with 15% NaOH soln. Completely displace air in tubing connecting it to piercing app. with H<sub>2</sub>O or NaOH soln and attach piercing device to bottle or can. Take care that no air is trapped in system that will be carried into buret during detn.

With valve of piercing device closed, pierce bottle crown or can by depressing hollow steel spike. Shake bottle or can until pressure reaches const max. value; then stop, and record pressure reading. Open valve on piercing app. cautiously and let gas-foam mixt. flow into absorption buret until pressure gage reads zero. Close valve and shake or tip buret (depending on its construction) until CO<sub>2</sub> is absorbed and gas vol. in buret reaches min. value. Adjust leveling bottle to equalize hydrostatic pressure and read vol. of "headspace air" contained in buret.

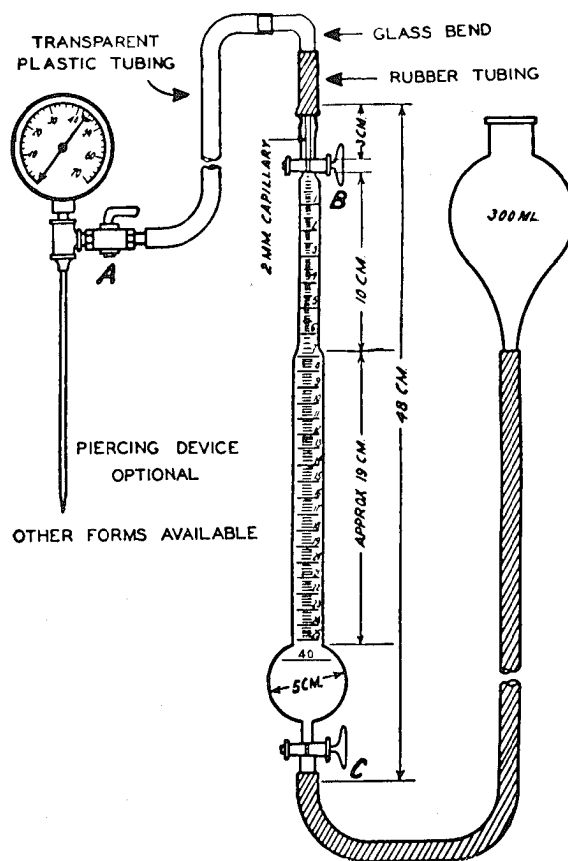

FIG. 10.01—Absorption buret (other forms available)

If detn of "total air" is also desired, continue evolution of gas from bottle or can by shaking it. Absorb evolved CO<sub>2</sub> by swirling and shaking buret. Continue shaking and CO<sub>2</sub> absorption until there is no further increase in vol. of unabsorbed gas in buret. Final vol. of unabsorbed gas may be considered the "air content" or "total air" of container.

Disconnect piercing device from package and insert thermometer to be sure that temp. is 25°. Det. headspace vol. as follows:

(a) *Bottles*.—Fill bottle to top with H<sub>2</sub>O and pour from it into 100 mL graduate until liq. level in bottle corresponds to scratch mark placed on it. Vol. in mL of liq. poured off is headspace vol.

(b) *Cans*.—Empty beer from weighed can and let it drain completely. Weigh empty can. Fill empty can with H<sub>2</sub>O and weigh. Subtract wt empty can from wt unopened can of beer to obtain wt of beer before opening can. Divide beer wt by sp gr of beer to obtain vol. beer in can in mL. Subtract wt empty can from wt can filled with H<sub>2</sub>O. Difference is wt H<sub>2</sub>O, equiv. to vol. in mL required to fill can completely. Subtract vol. beer from vol. can to obtain headspace in can before opening. (This detn of headspace in cans is only approx. correct, due to unknown degree of bulging of cans under pressure, distortion of end on opening or puncturing can, and difficulty of accurately defining when can is completely filled with H<sub>2</sub>O.)

Calc. % CO<sub>2</sub> by wt and vol. as follows:

$$\% \text{ CO}_2 \text{ by wt} = [P - (\text{mL "head-space air"} \times 14.7 / \text{mL headspace})] \times 0.00965,$$

where  $P$  = absolute pressure in psi = gage pressure + 14.7.

$$\begin{aligned} \text{Vol CO}_2 &= \% \text{ CO}_2 \text{ by wt} \times \text{sp gr of beer} / 0.1976 \\ &= \% \text{ CO}_2 \text{ by wt} \times 5.0607 \times \text{sp gr of beer.} \end{aligned}$$

Report % by wt to second decimal, and vol CO<sub>2</sub> to first decimal.

#### Foam Collapse Rate ( $\delta$ )—Official Final Action

##### *Sigma Value Method*

#### 10.051

##### *Apparatus*

(a) *Special foam funnel*.—Marked at 800 mL. Kontes Glass Co. drawing No. 9357B or CGW drawing No. XA-7396 (Science Products Div., Corning Glass Works).

(b) *Stopwatch*.—Or clock that indicates sec.

#### 10.052

##### *Determination*

Perform detn at room temp. (22–27°).

Attemperate beer in container to 25±0.5° in H<sub>2</sub>O bath or const temp. room.

Clean foam funnel thoroly with warm detergent soln; rinse well, first with warm H<sub>2</sub>O and then with H<sub>2</sub>O at ca 25°. Clamp funnel at suitable ht to ringstand and let drain 1 min.

Make foam detns immediately after draining.

Open beer container, rest side of container on funnel edge, and direct stream of beer into center of funnel, pouring smoothly to avoid entrapping air in beer. Pour until foam reaches 800 mL mark, start stopwatch, and cover funnel with ≥100 mm watch glass. After 30 sec, open stopcock to let all beer flow out in 25–30 sec at as uniform rate as possible; open stopcock wide for last 1–2 sec until small amt of foam drains out. Immediately close stopcock, reset stopwatch to 0, and start it again. Discard drained beer.

After exactly 200 sec, let beer formed from collapsed foam flow out into 100 mL graduate at such rate that all beer drains off in 25–30 sec (total time 225–230 sec). Just as last drop of beer drains off, close stopcock and stop stopwatch. Record time in sec as "t" and mL drained beer as "b."

To collapse remaining foam, wash down inside of funnel with 2 mL isopropanol or *n*-BuOH delivered from fine-point pipet. Open stopcock wide and let liq. drain into 25 mL graduate 1 min.

Record mL drained beer as "c" (mL liq. drained – 2 mL defoaming agent).

#### 10.053

##### *Calculations*

$$\text{Sigma value} = t / (2.303 \log[(b + c)/c]),$$

where  $t$  = time of foam collapse (225–230 sec),  $b$  = mL beer collapsed from foam in time  $t$ ,  $c$  = mL beer from residual foam at time  $t$ . Report to nearest whole number.

#### *Foam Flashing Method*

#### 10.054

##### *Apparatus*

(a) *Compressed carbon dioxide gas*.—Contained in steel cylinder with reducing valve.

(b) *Pressure surge tank*.—Approx. 7.6 L (2 gal.), fitted with inlet and outlet gas connections, bleeder valve, and pressure gage. (Or use ¼" Type 10 Pressure Regulator, 2–60 psi, Lexington Control, Inc., PO Box 132, Burlington, MA 01803.)

(c) *Orifice foam flashing apparatus*.—Foam flashing orifice tube connected to stainless steel Master Volume Gage Bottle attachment seated pressure-tight on open bottle. Permits application of gas pressure to expel beer from bottle as foam. Furnished with inlet valve (No. 1) and outlet valve (No. 2), and adjustable ht sample tube (Micromat Co., 185 Rt 17, North Mahwah, NJ 07430).

(d) *Graduated cylinder*.—200 mL, 4.6 cm id × 12 cm deep, graduated in 5 mL intervals to brim (Labtician Products Co., 190–99th Ave, Hollis, NY 11423) (500 mL graduate truncated smoothly at 200 mL mark may be used).

(e) *Stopwatch*.—Or clock that indicates sec.

#### 10.055

##### *Determination*

Perform detns at room temp. (22–27°).

Clean grease from equipment, and connect CO<sub>2</sub> cylinder, pressure surge tank, and orifice foam flashing app. in that order, with Tygon tubing. Be sure all connections are gas-tight. Set CO<sub>2</sub> cylinder reducing valve to 31 lb gage pressure (1600 mm Hg, 214 KPa). Replace air in pressure surge tank with CO<sub>2</sub>. Close inlet valve (No. 1) and adjust pressure on surge tank to 29 lb (1500 mm Hg, 200 KPa), using bleeder valve to reduce excess pressure.

Attemperate bottles of beer to 25±0.5° in H<sub>2</sub>O bath or const temp. room.

Clean 200 mL graduate with detergent soln, rinse well with H<sub>2</sub>O, and fill with H<sub>2</sub>O. Let graduate drain free of H<sub>2</sub>O 1 min; then secure graduate beneath foam flashing orifice tube in upright position with clamp and ringstand so placed that they do not interfere with reading graduations.

Open attemperated beer bottle; fit its neck to bottle attachment of orifice foam flashing app. to secure bottle in place. Raise sample tube so that it is above liq. level in headspace. Open inlet and outlet valves (No. 1 and No. 2) to flush headspace and connecting Tygon tubing with CO<sub>2</sub>. Close valves. Bring sample tube to ca 1 cm from bottom of bottle and secure tube in this position by tightening gasket sealing nut at top of bottle attachment portion of app. Open inlet valve (No. 1). If pressure on surge tank drops, readjust to 29 lb (1500 mm Hg, 200 KPa).

With orifice tube diverted from foam receiving cylinder, open outlet valve (No. 2) and let outflowing foam go to waste for 10 sec. Then direct stream of foam into measuring cylinder by placing orifice tube at oblique angle below (tip ca 6 mm away

from) rim of inside wall of cylinder. Fill cylinder just to overflowing. Just as overflow begins, divert stream of foam out of cylinder, start stopwatch, and close outlet valve (No. 2) to stop flow of foam. After exactly 90 sec, read mL liq. beer formed from collapsed foam. Wash down cylinder walls with 2 mL isopropanol from pipet and carefully swirl liq. in cylinder so all foam collapses. Read mL liq. at rest; this reading - 2 mL (added isopropanol) = total mL beer formed by collapse of 200 mL foam.

**10.056****Calculations**

Foam Value Units (FVU) =  $200 \times (B_2 - B_1)/B_2$ , where 200 = arbitrary factor chosen to give FVU generally near 100,  $B_2$  = total mL beer from collapse of 200 mL foam,  $B_1$  = mL beer formed from foam collapsed in 90 sec. Report mL to nearest whole number.

**Calcium (9)—Official Final Action****ASBC Method I****10.057****Reagents**

(a) *Ammonium oxalate soln.*—Satd soln (ca 6%) of  $(\text{NH}_4)_2\text{C}_2\text{O}_4 \cdot \text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ .

(b) *Buffer soln.*—pH 10.0. Dissolve 67.5 g  $\text{NH}_4\text{Cl}$  in 200 mL  $\text{H}_2\text{O}$ . Measure pH, and add  $\text{NH}_4\text{OH}$  (ca 200 mL) to pH 10.0. Dil. to 1 L.

(c) *Eriochrome black T indicator soln.*—Dissolve 0.1 g indicator (Eastman Kodak Co., No. P6361, or equiv.) in 25 mL MeOH contg 1 g  $\text{H}_2\text{NOH.HCl}$ . Store <2 months.

(d) *Sodium sulfide soln.*—2%. Dissolve 2 g  $\text{Na}_2\text{S}$  in 100 mL  $\text{H}_2\text{O}$ .

(e) *Magnesium std soln.*—1.00 mg/mL. Dissolve 1.00 g Mg turnings in 100 mL 0.1N HCl and dil. to 1 L with double distd  $\text{H}_2\text{O}$ .

(f) *Disodium dihydrogen EDTA std soln.*—0.1%. Dissolve 1 g  $\text{Na}_2\text{H}_2\text{EDTA}$  in 1 L  $\text{H}_2\text{O}$ . Stdze against Mg std soln.

**10.058****Standardization**

Pipet 5 mL Mg std soln into 250 mL erlenmeyer and add 50 mL  $\text{H}_2\text{O}$  and 1 mL  $\text{Na}_2\text{S}$  soln. Prep. blank soln with 50 mL  $\text{H}_2\text{O}$  and 1 mL  $\text{Na}_2\text{S}$  soln. Add 5 mL buffer soln and 10 drops indicator soln to each erlenmeyer. Titr. flask contg Mg with EDTA std soln until permanent blue color exactly matches blank. Titr. 3 aliquots and use av. to calc. titer Mg soln,  $M = 5/\text{mL EDTA std soln}$ .

Calc. Ca factor,  $C = (40.08/24.32) \times M$ .

**10.059****Determination**

(a) *Total calcium and magnesium.*—Pipet 5 mL prepd sample, **10.001**, into 250 mL erlenmeyer and add 40 mL  $\text{H}_2\text{O}$ , 1 mL  $\text{Na}_2\text{S}$  soln, 5 mL buffer soln, and 10 drops indicator soln. Titr. immediately with EDTA std soln. mL EDTA std soln = X.

(b) *Magnesium.*—Pipet 25 mL prepd sample, **10.001**, into 125 mL erlenmeyer and add 0.5 mL  $(\text{NH}_4)_2\text{C}_2\text{O}_4 \cdot \text{H}_2\text{O}$  soln and 2 drops buffer soln. Refrigerate 2 hr at 0–2°. Filter thru Whatman No. 40, or equiv., paper. Add 1 drop HCl to filtrate. Pipet 5 mL filtrate into 250 mL erlenmeyer and add 40 mL  $\text{H}_2\text{O}$ , 1 mL  $\text{Na}_2\text{S}$  soln, 5 mL buffer soln, and 10 drops indicator soln. Titr. immediately with EDTA std soln. mL EDTA std soln = Y.

$$\text{ppm Ca} = [X - (25.5Y/25)] \times C \times 200$$

**ASBC Method II****10.060****Reagents**

(a) *Calcein indicator soln.*—Dissolve 0.2 g indicator (G. Frederick Smith Chemical Co., Eastman Kodak Co., or equiv.) in 100 mL  $\text{H}_2\text{O}$  contg 1 mL 5N NaOH.

(b) *EDTA std soln.*—1 mL = 1 mg  $\text{CaCO}_3$ . Available from Hach Chemical Co., PO Box 389, Loveland, CO 80537; Betz Laboratories, Inc., 4636 Somerton Rd, Trevose, PA 19047; or equiv.

**10.061****Determination**

Pipet 20 mL prepd sample, **10.001**, into 250 mL erlenmeyer. Add 100 mL  $\text{H}_2\text{O}$ , 3 mL 5N NaOH, and 0.5 mL calcein indicator soln. Swirl to mix. Titr. with EDTA soln at 1 drop/sec, using overhead light and black background until yellow-green fluorescence is replaced by orange-brown color. mg Ca/L = mL EDTA std soln  $\times 20$ .

**Copper****Direct, Nonashing Method (10)  
Official Final Action****10.062****Reagents**

(a) *Zinc dibenzylthiocarbamate (ZDBT) soln.*—0.5%. Dissolve 5 g ZDBT (available from Uniroyal Chemical under trade name "Arazate") in toluene and dil. to 1 L with toluene. Filter, if necessary, thru Whatman No. 42 paper, and store in brown bottle in cool, dark place.  $\text{CCl}_4$  may be used instead of toluene.

(b) *Copper std solns.*—(1) *Stock soln.*—1 mg/mL. Dissolve 3.93 g  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  (free of whitish deposit of lower hydrates) and dil. to 1 L with  $\text{H}_2\text{O}$ . Or dissolve 1.000 g pure Cu wire or foil in 75 mL  $\text{HNO}_3$  (1+4) by warming. Boil to expel fumes, cool, and dil. to 1 L with  $\text{H}_2\text{O}$ . (2) *Working soln.*—10  $\mu\text{g}/\text{mL}$ . Prep. immediately before use by dilg 5 mL stock soln with Cu-free distd  $\text{H}_2\text{O}$  to 500 mL in vol. flask.

(c) *Copper-free distilled water.*—Ext distd  $\text{H}_2\text{O}$  with ZDBT soln in separator.

**10.063****Apparatus**

(a) *Photometer.*—Any com. instrument with blue filter (430–460 nm) or spectrophtr set at 435 nm.

(b) *Copper-free centrifuge tubes.*—Clean and rinse 50 mL centr. tubes; add 15 mL  $\text{H}_2\text{O}$ , 3 mL  $\text{H}_2\text{SO}_4$  (1+3), and 5 mL ZDBT soln. Stopper with corks or glass stoppers and shake thoroly. Discard soln and let tube drain.

**10.064****Preparation of Standard Curve**

Into series of cleaned, corked or g-s, 50 mL centr. tubes add 0.0, 1.0, 2.0, 3.0, 4.0, and 5.0 mL Cu working std soln, contg 0.0, 0.4, 0.8, 1.2, 1.6, and 2.0 ppm Cu, resp. Add 25 mL beer, degassed as in **10.065**, and 1 drop *n*-hexyl alcohol; mix, and proceed as in **10.066**.

Color over this range follows Beer's law. Calc. factor,  $F$ , to convert  $A$  to ppm Cu after subtracting  $A$  of std contg 0.0 ppm Cu from those contg added Cu. If instrument response is not linear, use calibration curve.

**10.065****Preparation of Sample**

Cool bottle or can and shake thoroly immediately before opening. Let gas bubbles leave liq. before removing cap or puncturing can. Discard ca  $\frac{1}{3}$  of sample and degas by swirling. Remove sample directly from container.

**10.066****Determination**

To cleaned 50 mL centrf. tube, add 25 mL cold sample, measured in graduate, 3 mL  $\text{H}_2\text{SO}_4$  (1+3), and 1 mL 30%  $\text{H}_2\text{O}_2$ . If foam interferes with sample measurement, add 1 drop hexyl alcohol. Mix, and place tube in boiling  $\text{H}_2\text{O}$  bath 0.5 hr. If excessive foaming occurs, add 1 drop hexyl alcohol. Remove tube and cool to 25°. Add 5 or 10 mL, accurately measured, ZDBT soln, depending upon size of photometer cell, and stopper tube. Ext at 25° by shaking vigorously 60 times. Re-ext again 4 times, giving 60 snapping shakes each time to obtain fine emulsion, allowing partial sepn between extns. Digested sample must be shaken vigorously with the ZDBT soln; thoro and complete emulsification must be obtained during each series of extns or results may be low.

Centrf. tube 2–3 min and draw off clear, colored layer to photometer cell of same size used in calibration, and det. *A*. If droplets of aq. layer are carried into pipet, remove by flowing solv. from pipet down wall of clean, dry test tube.  $\text{H}_2\text{O}$  droplets will adhere to test tube and clear solv. can be poured off into cell.

Prep. reagent blank by extg, in clean 50 mL centrf. tube, 25 mL Cu-free  $\text{H}_2\text{O}$  at 25° and 3 mL  $\text{H}_2\text{SO}_4$  (1+3) with 5 (or 10) mL ZDBT soln and det. *A*<sub>1</sub>. To correct for *A* of color extd by solv., perform entire detn, omitting ZDBT soln, but shaking with toluene (or  $\text{CCl}_4$ ) and det. *A*<sub>2</sub>. Do not give tubes used for this solv.-extractable beer color blank preliminary cleaning with ZDBT soln, since carryover of ZDBT may give high readings.

$$\text{ppm Cu} = [A - (A_1 + A_2)] \times F,$$

where *F* is factor for converting *A* to ppm Cu.

**Cuprethol Method (11)—Official Final Action****10.067****Apparatus**

(a) *Photometer*.—Any com. instrument with blue-green or green filter, or spectrophtr set at 445 nm and with 40–50 mm cells.

(b) *Copper-free glassware*.—Clean all glassware with 0.1*N*  $\text{HNO}_3$  and rinse thoroly with Cu-free distd  $\text{H}_2\text{O}$ .

**10.068****Reagents**

(a) *Diethanolamine soln*.—Dissolve 4.0 mL  $(\text{HOCH}_2\text{CH}_2)_2\text{NH}$  (Eastman Kodak Co., No. 1598) in 200 mL MeOH.

(b) *Carbon disulfide soln*.—Add 1.0 mL  $\text{CS}_2$  (free of pptd S) to 200 mL MeOH.

(c) *Cuprethol soln*.—Mix 3 vols soln (a) and 1 vol. soln (b). Prep. fresh daily. Also mix equal vols soln (a) and MeOH for blank.

(d) *Copper std solns*.—Prep. as in 10.062(b).

(e) *Buffer soln*.—pH 4.4. Dissolve 63.3 g anhyd. NaOAc in ca 800 mL  $\text{H}_2\text{O}$  contg 65 mL HOAc. Dil. to 1 L with  $\text{H}_2\text{O}$ .

(f) *Copper-free distilled water*.—Use distd  $\text{H}_2\text{O}$  redistd from all-glass app. thruout method.

**10.069****Preparation of Standard Curve**

Into series of g-s 100 mL vol. flasks add 0.0, 1.0, 2.0, 4.0, 8.0, and 12.0 mL Cu working std soln contg 0.0, 0.4, 0.8, 1.6, 3.2, and 4.8 ppm Cu, resp. Add  $\text{H}_2\text{O}$  to 12 mL in each flask. Dil. to vol. with degassed low-Cu beer, 10.065, mix, and proceed as in 10.070. Use 0.0 sample to zero instrument, and obtain *A* or scale readings for 0.1, 0.2, 0.4, 0.8, and 1.2 ppm added Cu. *A* over this range follow Beer's law. Calc. av. factor, *F*, converting *A* or scale readings to ppm Cu. If instrument response is not linear, draw and use smooth curve for calcg ppm Cu.

**10.070****Determination**

Slowly pour 50 mL cold beer into 50 mL graduate; avoid foaming. Transfer to 125 mL flask, add 25 mL buffer soln, (e), and mix. Measure two 30 mL aliquots in 50 mL graduate and transfer to sep. 50 mL flasks. Add 3 mL cuprethol soln, (c), to one flask and 3 mL blank soln to other. Mix each and let stand 10 min. Zero instrument with blank. Det. *A* in same size cell and at same wavelength used in calibration. Calc. ppm Cu by multiplying *A* or scale reading by *F*, or use curve.

**Iron (12)—Official Final Action****10.071****Apparatus**

*Photometer*.—Spectrophtr set at ca 505 nm or photometer with filter in blue-green region, 500–550 nm, or preferably, 505–520 nm.

**10.072****Reagents**

(a) *Color reagent*: (1) *2,2'-Bipyridine*.—0.2%. Dissolve 1 g 2,2'-bipyridine in 20 mL HOAc (1+2) and dil. to 500 mL with  $\text{H}_2\text{O}$ ; or—

(2) *o-Phenanthroline*.—0.3%. Dissolve 1.5 g *o*-phenanthroline in 500 mL  $\text{H}_2\text{O}$  at 70°.

(b) *Iron std soln*.—0.1 mg/mL. (1) *From iron wire*.—Dissolve 0.500 g reagent grade Fe wire, wiped free of oxide, in 5 mL HCl (1+4) and 1 mL  $\text{HNO}_3$ . Cover with watch glass, heat, and evap. to dryness; add  $\text{H}_2\text{O}$  and evap. to dryness again. Dissolve residue in 3–5 mL HCl, cool, and transfer quant. to 500 mL vol. flask. Add 2 drops satd Br- $\text{H}_2\text{O}$ , dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Transfer 50 mL of this soln to 500 mL vol. flask, add 2 drops Br- $\text{H}_2\text{O}$ , dil. to vol. with  $\text{H}_2\text{O}$ , and mix.

(2) *From ferrous ammonium sulfate*.—Dissolve 3.512 g  $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 5 mL HCl, transfer quant. to 500 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Transfer 50 mL of this soln to 500 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix.

(c) *Ascorbic acid*.—USP, ground to fine powder.

**10.073****Preparation of Standard Curve**

Prep. series of beer stds contg 0.0, 0.25, 0.50, 1.00, 2.00, and 3.00 ppm Fe as follows: Pipet 0.0, 0.25, 0.50, 1.00, 2.00, and 3.00 mL Fe std soln to series of 100 mL vol. flasks, add, from pipet, enough  $\text{H}_2\text{O}$  to total 3.00 mL, and dil. to vol. with decarbonated beer, 10.074. Depending upon size cell to be used, develop color in 25 or 50 mL aliquots of each of the beer stds as in 10.075(a) or (b).

If *T* values are obtained, convert to  $A = -\log T$ , and plot *A* against ppm Fe. If straight line results, calc. factor, *m*, for converting *A* to ppm Fe, *y*, by use of equation  $y = mA + b$  (*b* = 0 if line passes thru origin). If instrument response is such that curve is obtained, use this curve to calc. results.

**10.074****Preparation of Sample**

Adjust temp. of beer to 20–25°. Decarbonate by transferring sample to large erlenmeyer and shaking, first gently and then vigorously, until all gas is released. Do not filter unless necessary. If filtration is required, make sure filter paper is Fe-free by spotting sample of paper with drop of reagent prep'd by dissolving 25 mg ascorbic acid in 2 mL color reagent, 10.072(a).

If beer sample is suspected of high Fe content, degas by shaking only, and permit foam to subside before sampling.

**10.075****Determination**

Pipet 2 aliquots of degassed beer (25 or 50 mL as used in prepn of std curve) into 50 mL or 125 mL erlenmeyers; add 25

mg ascorbic acid to each aliquot, and add 2 mL color reagent, (a), to one and 2 mL H<sub>2</sub>O to other.

(a) Stopper and heat both aliquots 15 min at 60°, or

(b) let stand 30 min at room temp.

Cool, and read both solns in photometer against H<sub>2</sub>O as ref., or read colored aliquot against beer blank as ref. Use same size cell and wavelength as used in prepn of std curve.

#### 10.076

#### Calculations

If H<sub>2</sub>O is used as ref. and factor is used, ppm Fe =  $(A_{\text{sample}} - A_{\text{blank}}) \times \text{factor}$ . If values are taken from std curve, ppm Fe = ppm Fe in sample - ppm Fe in blank.

If beer blank is used as ref. and factor is used, ppm Fe =  $A_{\text{sample}} \times \text{factor}$ . If values are taken from std curve, ppm Fe = ppm Fe directly.

#### 10.077 Other Metals

See Chapter 25.

#### 10.078 Chlorides—Official Final Action

Place 50 mL sample in Pt dish, add 20 mL 5% Na<sub>2</sub>CO<sub>3</sub> soln, and proceed as in 3.071. Det Cl as in 3.072 or 3.074.

#### Sulfur Dioxide (13)—Official Final Action

#### 10.079

#### Reagents

(a) *Color reagent*.—Weigh 100 mg *p*-rosaniline.HCl into 250 mL vol. flask and dissolve in ca 200 mL H<sub>2</sub>O. Add 40 mL HCl (1+1), mix, and dil. to vol. with H<sub>2</sub>O. Let stand ca 15 min before use. Store in brown, g-s bottle in refrigerator.

(b) *Formaldehyde soln*.—Dil. 5 mL 40% HCHO soln to 1 L with H<sub>2</sub>O and store in brown, g-s bottle in refrigerator.

(c) *Mercury stabilizing soln*.—Dissolve 27.2 g HgCl<sub>2</sub> and 11.7 g NaCl in H<sub>2</sub>O, and dil. to 1 L with H<sub>2</sub>O. (Caution: See 51.079.)

#### 10.080

#### Calibration

Accurately weigh ca 250 mg NaHSO<sub>3</sub> into exactly 50 mL 0.1*N* I soln in g-s flask. Let stand at room temp. 5 min. Add 1 mL HCl, and titr. excess I with 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, using 1% aq. starch soln as indicator (1 mL 0.1*N* I consumed = 3.203 mg SO<sub>2</sub> or 5.20 mg NaHSO<sub>3</sub>). From results of NaHSO<sub>3</sub> assay, prep. soln contg 10 mg SO<sub>2</sub>/mL (ca 8.6–9.0 g NaHSO<sub>3</sub>/500 mL) (*Soln I*).

Transfer 100 mL Hg stabilizing soln to 500 mL g-s vol. flask. Add 1.00 mL *Soln I*, and dil. to vol. with H<sub>2</sub>O (1 mL = 20 µg SO<sub>2</sub>) (*Soln II*).

Using 10 mL graduate contg 1 drop *n*-hexyl alcohol as antifoam, transfer 10 mL portions of cold, undegassed beer (preferably of low SO<sub>2</sub> content) into series of eight 100 mL vol. flasks. To series add 0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, and 8.0 mL *Soln II* (0–160 µg SO<sub>2</sub>). Dil. to vol. with H<sub>2</sub>O, and mix. Transfer 25 mL aliquots of each soln to sep. 50 mL vol. flasks. To each flask, add 5 mL color reagent. Mix, and add 5 mL HCHO soln. Mix, dil. to vol. with H<sub>2</sub>O, mix, and hold in 25° H<sub>2</sub>O bath 30 min. Read color in spectrophtr at 550 nm or in photometer with green filter. Plot *A* as ordinates against µg SO<sub>2</sub> added to beer as abscissas (color follows Beer's law over range). Calc. calibration factor *F*, converting readings to µg SO<sub>2</sub> in 25 mL aliquot used, or convert directly to ppm SO<sub>2</sub>.

#### 10.081

#### Preparation of Sample

Using pipets, add 2 mL Hg stabilizing soln and 5 mL 0.1*N* H<sub>2</sub>SO<sub>4</sub> to 100 mL vol. flask. Measure 10 mL cold, undegassed beer into 10 mL graduate contg 1 drop *n*-hexyl alcohol, and add to vol. flask. Swirl gently, and add 15 mL 0.1*N* NaOH. Swirl, and

hold 15 sec. Add 10 mL 0.1*N* H<sub>2</sub>SO<sub>4</sub>, then H<sub>2</sub>O to vol., and mix thoroly. Transfer 25 mL aliquot to 50 mL vol. flask.

#### 10.082

#### Determination

To soln in 50 mL vol. flask, add 5 mL color reagent, swirl, add 5 mL HCHO soln, swirl, and dil. to vol. with H<sub>2</sub>O. Mix, and hold in 25° bath 30 min. Read color as in 10.080, using cells of same size and same instrument settings.

Correct for blank as follows: Measure 10 mL cold, undegassed beer into 100 mL vol. flask. Add 0.5 mL 1% aq. starch soln, then 0.05*N* I soln, dropwise until permanent bluish tinge persists. Add 1 drop more, dil. to vol., and mix thoroly. When blue fades, develop color in 25 mL aliquot as above.

(Color readings for I blanks are usually low and uniform; when test is performed on series of similar beers, blank tests on all may be unnecessary.)

$$\text{ppm SO}_2 = (A_s - A_b) \times F,$$

where *A<sub>s</sub>* = *A* of sample (or photometric reading with green filter equiv. to *A*), *A<sub>b</sub>* = *A* of I blank, and *F* = factor derived from 10.080 for converting *A* to µg SO<sub>2</sub> in aliquot, or directly to ppm SO<sub>2</sub>.

#### 10.083 Caramel—Official Final Action

See 11.055.

#### Beer Bitterness (14)—Official Final Action

(Certain preservatives, such as heptyl-*p*-hydroxybenzoate and sorbates and possibly some brewing adjuncts or coloring agents, may contribute to *A* at wavelengths specified. Interference from UV-absorbing material is greater for Bitterness Units method than for Iso-Alpha Acids.)

#### Bitterness Units

#### 10.084

#### Reagents

(a) *2,2,4-Trimethylpentane (isooctane)*.—Spectral grade or equiv. (ASTM certified ref. fuel grade isooctane may be used after 1 distn or use practical grade isooctane, purified by passage thru silica gel column (12–28 mesh, Fisher Scientific Co. No. S-156, grade 408).) *A* at 275 nm in 1 cm cell should be equiv. to that of H<sub>2</sub>O (*A* ≤ 0.005).

(b) *Octyl alcohol*.—Reagent grade or redistd equiv. One drop added to 20 mL isooctane increases *A* at 275 nm ≤ 0.005 in 1 cm cell.

#### 10.085

#### Apparatus

(a) *Mechanical shaker*.—Platform or wrist-action type with extending arm adjusted vertically so that tube is held horizontally.

(b) *Spectrophotometer*.—For use in UV range.

(c) *Centrifuge tubes*.—50 mL, g-s or screw-cap with Teflon lining.

#### 10.086

#### Determination

Transfer 10.0 mL chilled (10°C, 50°F) carbonated beer to 50 mL centr. tube, using pipet which has minute amt octyl alcohol in tip. Add 1 mL 3*N* HCl and 20 mL isooctane. Tightly stopper centr. tube and shake vigorously 15 min on mech. shaker. If required, centr. long enough to sep. phases. Immediately transfer portion clear upper (isooctane) layer to cell. Set instrument to read 0 *A* at 275 nm for isooctane-octyl alcohol blank (20 mL isooctane + 1 drop octyl alcohol). Record *A* in 1 cm cell at 275 nm.

$$\text{Calc. bitterness units (BU)} = A_{275} \times 50.$$

Report BU to nearest 0.5 unit.

**Iso-Alpha Acids****10.087****Reagents**

(a) *2,2,4-Trimethylpentane (isooctane)*.—See 10.084(a). *A* at 255 nm in 1 cm cell should be equiv. to that of freshly redistd H<sub>2</sub>O from all-glass still.

(b) *Methanol*.—Reagent grade, with *A* ≤ 0.04 at 260 nm in 1 cm cell compared with freshly redistd H<sub>2</sub>O from all-glass still.

(c) *Acid methanol*.—Mix 6.8 parts MeOH with 3.2 parts 4*N* HCl.

(d) *Alkaline methanol*.—Just before use, mix 1.0 mL 1.5*N* NaOH with 500 mL MeOH.

(e) *Octyl alcohol*.—See 10.084(b).

**10.088****Apparatus**

See 10.085.

**10.089****Determination**

Transfer 15.0 mL chilled carbonated beer to 50 mL centr. tube, using pipet with minute amt octyl alcohol in tip. Add 2.0 mL 6*N* HCl and 15.0 mL isooctane. Close tube tightly and shake vigorously on mech. shaker ≥ 30 min until completely extd. Place tube in centr. set to run at highest permissible speed. Centr. long enough to sep. phases. Break difficult emulsions by adding 1 drop detergent to centr. tube. Verify that detergent does not contribute to *A* at 255 nm. (Union Carbide Corp. "Tergitol Anionic 7" (Na heptadecyl sulfate) is satisfactory.)

Transfer 10.0 mL clear upper layer to 50 mL g-s graduate contg 10.0 mL acid MeOH. Stopper and invert 100 times at rate causing contents to pass from end to end. Let phases sep.

Transfer 5.0 mL upper layer to 25 mL vol. flask and dil. to vol. with alk. MeOH. Read *A* in 1 cm cell at 255 nm in spectrophtr set to read 0 *A* for reagent blank consisting of 5 mL isooctane dild to 25 mL with alk. MeOH.

$$\text{ppm Iso-alpha acids of beer} = 96.15 A_{255} + 0.4.$$

Report to nearest 0.5 ppm.

**Proteolytic Chillproofing Enzymes (15)**  
**Official Final Action**

**Casein Coagulation Method****10.090****Reagent**

*Substrate mixture*.—Thoroly mix by grinding in large mortar and pestle 50 g com. skim milk powder (do not use special casein powder prepd for microbiological or other uses), 5.0 g L(+)-cysteine.HCl.H<sub>2</sub>O, 4.4 g Na<sub>2</sub>HPO<sub>4</sub>, 2.5 g NaCl, and 1.8 g citric acid.H<sub>2</sub>O. Store at 0–4° and let warm to room temp. before use.

**10.091****Test**

Place ca 100 mL degassed beer into 150 mL beaker and adjust pH to 6.4 ± 0.1 with 1*N* NaOH. Transfer 50 mL aliquot to 25 × 200 mm test tube contg 250 ± 30 mg substrate mixt. Suspend substrate mixt. with rubber-tipped glass stirring rod. Invert tube twice to mix uniformly, and place in 60° H<sub>2</sub>O bath.

Progressive change in appearance of suspension, initially clouding, then formation of "pebbles," followed by coagulation and settling of casein indicates pos. test. Control beers, without chill-proofing enzymes, should remain unchanged. If semi-quant. data are desired, record time required to reach first stage of "pebbling."

**MALT****10.092 Sampling—Official Final Action**

For complete descriptions of trier, divider, sampler, and bushel weight tester, see "Grain Inspection Manual" GR Instruction 918-6 (latest edition available from Federal Grain Inspection Service, Standardization Div., US Dept. of Agriculture, 1400 Independence Ave SW, Washington, DC 20250).

(a) *Bulk malt in cars or bins*.—Using 60" (1.5 m) trier, take ≥ 6 probes from different parts of car, preferably 2 from center and 2 from each end.

(b) *Bulk malt during discharge thru spouts or openings*.—At different times during filling or unloading of car, take, with trier or Pelican sampler, ≥ 6 samples, each representing complete cross section of grain stream from spout.

(c) *Bagged malt*.—Sample lengthwise thru center of open bags, ≥ 2% of bags selected from different parts of car or storage room. Use 36" (0.9 m) trier.

Indicate approx. proportion of inferior grain and take representative samples from each portion as outlined above. Immediately place each portion of sample in suitable large dry container and keep tightly closed.

**10.093 Preparation of Sample—Official Final Action**

Divide samples, either by quartering or by using sample divider, until ca 1.4 kg (3 lb) remains. Place reduced sample in air-tight container (preferably tin with screw or friction-type cover); do not use cartons, bags, wooden boxes, glass Mason jars, or wrapping paper. Remove foreign particles, such as stone, wood, and twine. Do not remove foreign seeds or dust particles.

**Bushel Weight (16)—Official Final Action****10.094 Method I**

Place sample in filling hopper of Winchester tester, open slide underneath, and let malt fill measuring cylinder to overflowing. Without jarring, level off with straight-edge longer than diam. of measuring cylinder, making one forward stroke consisting of 3 distinct zigzag motions. Weigh and report to nearest 100 g (¼ lb).

**10.095 Method II**

Weigh 110 g sample to nearest 0.1 g and pour evenly into metal funnel provided with plunger discharge and placed on top of 250 mL cylinder graduated to meet NBS specifications. (Funnel must fit snugly into graduate and be large enough to hold the grain without danger of spilling when plunger is raised.) Then drop material into cylinder by pulling plunger up. Do not jar or tap cylinder during operation or before reading vol., and do not read uppermost grain level, as compensation must be made for ends of few kernels that protrude. If grain surface has slant, repeat test.

Calc. bushel wt of malt (lb) as = 8545/vol. in mL of 110 g.

Const 8545 is derived from *W*, wt in lb of US (Winchester) bushel of 2150.42 cu in. (35,239 mL). If *V* = vol. in mL of 110 g malt,

$$110/453.6W = V/35,239.$$

$$W = 8545/V.$$

**10.096 Length of Acrospire—Procedure**

For methods (a) and (b), quarter sample until ca 200 kernels remain in 2 opposite quarters, and count out 100 kernels, rejecting those that are broken or those in which growth is not ascertainable.

(a) *Cutting*.—Hold each kernel, furrow downward, on flat surface with pair of tweezers, cut thru kernel longitudinally with razor blade or other sharp instrument, and examine cut acrospire in both halves, comparing its length with that of kernel. Tally according to classifications below.

(b) *Peeling*.—Remove husk covering acrospire with sharp instrument and examine acrospire length in comparison with kernel length. Tally according to classifications below.

(c) *Boiling*.—Boil 10–15 g av. sample with 100–150 mL H<sub>2</sub>O 20–30 min. After boiling, add cold H<sub>2</sub>O to cool contents of beaker. Decant, and pour grain on glass plate. Select 100 kernels at random, inspect acrospire, and tally according to classifications below.

Classify kernels as follows and report % in each group:

0–¼: those kernels without apparent growth, or having acrospire development up to, but not including, ¼ length of grain.

¼–½: those kernels having acrospire development from ¼ up to, but not including, ½ length of grain.

½–¾: those kernels having acrospire development from ½ up to, but not including, ¾ length of grain.

¾–1: those kernels having acrospire development of ¾ but not greater than entire length of grain.

Overgrown: those kernels having acrospire development in excess of length of grain.

If it is apparent that overgrown acrospire has been broken off during processing, include kernel in overgrown classification regardless of length of remaining stub.

#### 10.097 Mealiness—Procedure

Count out 100 kernels remaining from preceding test if method 10.096(a) or (b) was used. Otherwise select 100 kernels as in 10.096 and cut kernels in longitudinal halves. Det. % mealy, half glassy, and glassy kernels. In case of uncertainty, pierce starch body with sharp point; if mealy, it will break away and crumble from point.

Classify kernels as follows:

*Mealy kernels*—those kernels in which  $\leq \frac{1}{4}$  of the endosperm body is glassy.

*Half glassy*—those kernels in which  $> \frac{1}{4}$  but  $< \frac{3}{4}$  of the endosperm body is glassy.

*Glassy*—those kernels in which  $\geq \frac{3}{4}$  of the entire endosperm body is glassy.

#### 10.098 1,000 Kernel Weight—Procedure

Quarter sample until ca 500 kernels remain in 2 opposite quarters. Count out 500 kernels and weigh to nearest 0.1 g. Calc. results to 1,000 kernels on as-is and dry basis.

#### 10.099 Assortment—Procedure

Weigh 100 g from quartered sample to nearest 0.1 g. Place in top compartment of grader (frame and screens available from S. Howes Co. Inc., Silver Creek, NY 14136) and shake 3 min. Weigh portions remaining on various screens and in catch pan to nearest 0.1 g, and report % on each of the following screens:  $\frac{7}{64}$ ",  $\frac{6}{64}$ ",  $\frac{5}{64}$ ", and thru  $\frac{5}{64}$ ", in percentages totaling 100%. (When testing large berried malts (2 row, California, etc.), addn of  $\frac{8}{64}$ " screen is optional.)

#### 10.100 Mold—Procedure

Det. presence or absence of mold by visual inspection and report as "none," "trace," etc.

#### 10.101 Foreign Seeds and Broken Kernels—Procedure

Weigh 50 g sample. Pick out foreign seeds and broken kernels, classify, and report sep. in %.

#### Moisture—Official Final Action

##### 10.102

##### Apparatus

(a) *Weighing dish*.—Use glass bottle or Al dish, with tight-fitting cover, ca 40 mm diam. for 5 g sample, or 55 mm for 10 g sample.

(b) *Oven*.—With automatic control holding temp. within  $\pm 0.5^\circ$ , and large enough to hold all samples on 1 shelf in such manner that no sample is outside area indicated by test to give comparable results in duplicate samples. Stdze oven as follows: Place weighed duplicate samples in oven at 103–104° and dry 3 hr. Weigh, and redry 1 hr longer. If loss of moisture is  $> 0.1\%$ , raise temp.  $1^\circ$  and again test with new duplicate samples. Take, as std, lowest temp.  $< 106^\circ$  giving moisture content that, after 3 hr of drying, is within 0.1% of value attainable at same temp. within 4 hr. Keep ventilators of oven open during entire drying period, and do not open door during the 3 hr of drying.

##### 10.103

##### Preparation of Sample

(a) *If extract determination is to be made*.—Grind sample as in 10.108, and transfer in one continuous operation. When many samples are to be analyzed, grind first sample, remove beaker, and grind second sample while adjusting wt of first sample. Remove second sample, insert third sample, and repeat operation.

(b) *If extract determination is not to be made*.—Have sample of same fineness as finely ground malt used to det. ext. Weigh ca 5 g whole malt (or 10 g if 55 mm diam. weighing bottle is used) and grind thru clean dry mill directly into weighing bottle. Brush all malt from mill into weighing bottle and cover immediately.

##### 10.104

##### Determination

Weigh sample to 1 mg and place in oven previously heated to std temp. Remove cover of weighing bottle and heat exactly 3 hr at std temp. Replace cover, transfer to desiccator, cool to room temp., and weigh to 1 mg. Report moisture to nearest 0.1%.

#### Extract—Official Final Action

##### 10.105

##### Reagent

*Iodine std solns.*—(a) 0.01*N*. Dissolve 0.63 g I and 1.25 g KI in H<sub>2</sub>O, and dil. to 500 mL. (b) 0.02*N*. Dissolve 1.27 g I and 2.50 g KI in H<sub>2</sub>O, and dil. to 500 mL. Prep. fresh solns monthly and store in dark. For daily use, keep portion of soln in small brown dropper bottle.

##### 10.106

##### Apparatus

(a) *Mills*.—Miag-Seck (available from Buhler-Miag, Inc., PO Box 9497, Minneapolis, MN 55440). For fine grinding use cone-type, 300 rpm, and for coarse grinding, roller-type, 150 rpm.

(b) *Sieves*.—Half-ht, 8" std sieve No. 30 (with pan and cover). For classification of laboratory and brewery grindings use addnl std sieves Nos. 10, 14, 18, 60, and 100.

(c) *Mash beakers and counter weights*.—Made of either pure Ni, stainless steel, or brass, not Cu, and of such dimensions as to ensure tight connection between beakers and Miag-Seck mill while grinding.

If counter wts are used for the mash beakers, check tare wts frequently.

(d) *Mashing apparatus*.—Use beakers, stirrers, and solder made of same metal. Provide each stirrer with blade that in operation has clearance of ca 2 mm from bottom and 5 mm from wall of mash beaker. Blade is ca 8 mm wide, and each side has 45° pitch, arranged as in a propeller, to force mash upward. Speed of mash stirrer must be 80–100 rpm, each stirrer of each beaker having same speed. Mech. stir H<sub>2</sub>O in bath thoroly to assure uniformity of temp. and have level of H<sub>2</sub>O above max. mash level.

(e) *Gypsum plate*.—Thoroly mix 100 mL H<sub>2</sub>O with 135 g plaster of Paris. Pour mixt., while still free-flowing, into suitable flat molds (cigar boxes, etc.). Porcelain plate for color reactions, Coors No. 550, size 00, may be used.

(f) *Filter paper*.—Use S&S 32 cm fluted paper No. 560 (or No. 597, 32 cm, fluted by analyst) or Eaton-Dikeman Co., Mt. Holly Springs, PA 17065, 32 cm fluted paper No. 509 (or No. 609, 32 cm, fluted by analyst).

(g) *Funnels*.—Use short-stem glass funnels ca 20 cm diam. and do not let paper project above rim. Stem must extend 3–5 cm into receiving flask.

(h) *Flasks*.—Use dry 500 mL erlenmeyers marked at 100 mL level.

(i) *Pycnometers*.—Use any suitable pycnometer, but preferably Reischauer or Boot (vac.) type. Reischauer type is ca 15 cm high with neck ca 9 cm long and 2.5–3.5 mm id. Fine, well-defined mark is found 55–70 mm below upper rim of neck. When filled with H<sub>2</sub>O at 20° its capacity must be 48–50 g. Use ca 15 mL glass funnels to fill pycnometers.

Boot type is cylindrical and holds ca 50 g H<sub>2</sub>O at 20°. Vac. seal must be well rounded off and not pointed. Pycnometer opening is wide enough to permit easy filling and emptying, and stopper has fine capillary opening. Walls of bottle meet stopper in rising acute angle of ca 45° so that no depression or groove retaining moisture is formed at this point. (Available from Rascher and Betzold, Inc., 5410 N Damon Ave, Chicago, IL 60625.)

(j) *Emptying device for Reischauer pycnometer*.—Bend piece of metal capillary tubing (brass, stainless steel), <2 mm od, to ca 45° angle. End to be inserted into pycnometer must reach within 2–3 mm of bottom. Connect other end either to rubber aspirator bulb or to compressed air supply ≤5 psi.

(k) *Water bath*.—Automatically controlled. If automatic control is not available, use following app. Have H<sub>2</sub>O level of bath (5–15 L) reach above neck marks of pycnometer, keep H<sub>2</sub>O bath temp. at 20±0.05°, and read on accurate thermometer, calibrated to 0.1°. Maintain temp. of H<sub>2</sub>O bath by very slow but continuous flow of ice-H<sub>2</sub>O from container (2–4 L, contg ice and H<sub>2</sub>O). Regulate flow of ice-H<sub>2</sub>O by hand. Stir H<sub>2</sub>O in bath mech. and continuously without splashing.

## 10.107

### Standardization

(a) *Setting of mill*.—Use malt of following characteristics:

Variety: Malt made from 6-rowed midwestern variety of barley	
Moisture .....	4.2–4.8%
Ext in finely ground malt, dry basis .....	74.0–77.0%
Color of laboratory wort, 10.112 or 10.113 .....	≤1.8
Diastatic Power, dry basis .....	≥100°
Ratio sol. protein to total protein .....	36–42
Mealiness: Glassy .....	≤5%
Mealy .....	≥90%
Acrospire development: 0–¼ grown .....	≤5%
¾ to full grown .....	≥80%
Overgrown .....	≤5%
Assortment: From malt meeting above specifications, take that portion passing thru 7/64" screen and remaining on 9/64" screen for actual stdzg operation.	

*Fine grinding*.—Weigh 50 g specified malt into mash beaker, grind, and collect in same beaker. Mill must not be in motion when sample is introduced. Transfer to No. 30 sieve placed on receiving pan and shake in horizontal plane on flat surface 3 min, pausing every 15 sec long enough to give screen and pan 2 sharp taps on surface over which it is sliding. Transfer and weigh particles remaining on and adhering to screen. Consider mill as having stdzd setting when wt of ground malt remaining on No. 30 sieve is between 4.5 and 5.5 g (9–11%). Stdze mill at least twice yearly. Suitable mech. shaking device, giving equiv. results, may be used to stdze mill.

*Coarse grinding*.—Proceed as for *fine grinding*. Consider mill as having stdzd setting when portion of ground malt remaining on No. 30 sieve is between 37 and 38 g (74–76%).

(b) *Reischauer type pycnometer*.—Clean interior and exterior of pycnometer with chromic acid soln, discharge carefully with air, and wash several times with H<sub>2</sub>O, then alcohol, and finally ether. To remove last traces of ether vapor and to replace with laboratory air, connect dry metal capillary tubing to vac. and insert into pycnometer 1–2 min. Carefully wipe pycnometer, let stand few min, and det. wt to 0.2 mg.

Fill with freshly distd H<sub>2</sub>O and place in H<sub>2</sub>O bath held at 20±0.05°. Tap gently to force out air bubbles. After 25 min, remove liq. above mark with capillary pipet provided with small rubber bulb. To make final adjustment of meniscus, absorb last portion of liq. with thin strips of blotting paper; also remove any liq. adhering to inner surface of neck. Adjust H<sub>2</sub>O level so that lower part of meniscus rests on mark. Make all adjustments of liq. level within pycnometer neck while holding by neck, without touching body of pycnometer with hands. Keep body of pycnometer submerged during entire period of meniscus adjustment.

Raise pycnometer to room temp. by insertion into H<sub>2</sub>O bath kept at exactly that temp., and hold 10 min. Remove pycnometer, carefully dry exterior, and weigh to 0.2 mg. Subtract wt empty pycnometer. Difference in wts represents H<sub>2</sub>O capacity of pycnometer at 20°. Redet. tare wt and H<sub>2</sub>O capacity at frequent intervals.

(c) *Boot type pycnometer*.—Clean pycnometer and det. its wt in same way as for Reischauer type. Cool H<sub>2</sub>O in ice bath to temp. slightly <20°. Rinse pycnometer once with the cool H<sub>2</sub>O, fill, stopper, and dry exterior. Remove stopper, insert thermometer adjusted to 20° in H<sub>2</sub>O, and note temp., which should be 20±0.1°. If it is not, choose different "filling" temp., which may vary with analyst and season from 19.4° to 19.7° or more. Make subsequent detns, using predetd filling temp. Place cap over stopper and weigh.

Redet. wt, H<sub>2</sub>O capacity, and filling temp. at least weekly.

## 10.108

### Determination

*Fine grinding*.—Weigh ca 55 g sample (at room temp.) into tared mash beaker and grind thru mill set for stdzd fineness of grind. Collect finely ground malt in same mash beaker, carefully brushing malt particles remaining in mill into mash beaker. Mix, and without delay, place mash beaker with contents on balance accurate to within ±0.05 g under 750 g load and adjust wt malt to 50±0.05 g by removing excess into tared dish for moisture detn.

*Coarse grinding*.—Weigh 50.5 g sample (at room temp.) into tared mash beaker and grind thru mill set for stdzd coarseness of grind. Collect coarsely ground malt in same mash beaker, carefully brushing particles remaining in mill into mash beaker. Without delay, place mash beaker with contents on balance accurate to within ±0.05 g under 750 g load and adjust wt malt to 50±0.05 g by removing excess.

(a) *Mashing procedure.*—"Mash in" ground malt with 200 mL H<sub>2</sub>O at 46° and mix well with glass rod to prevent formation of lumps. Carefully rinse glass rod and wall of beaker with small amt H<sub>2</sub>O. Note odor of mash and report as aromatic, slightly aromatic, musty, green, stale, etc. Promptly place mash beakers in mashing app. contg H<sub>2</sub>O previously heated to 46°, and set stirrers in motion. Place thermometer in each mash beaker. Keep temp. at 45° exactly 30 min from time beakers were placed in mashing app. Raise mash temp. 1°/min to 70°. Add 100 mL H<sub>2</sub>O, previously heated to 70–71°, and hold mash 60 min at 70°. (Temp. deviations during mashing procedures should not exceed 0.5°.)

(b) *Conversion.*—Transfer drop of mash with thin glass rod (ca 3 mm diam.) onto absorbent gypsum plate, **10.106(e)**, or into one cavity of porcelain plate, and test with drop of 0.01*N* I soln on gypsum plate, or with drop of 0.02*N* I soln, **10.105(b)**, on porcelain plate. Make tests 5, 7, and 10 min after 70° is reached, and thereafter if necessary, at 5 min intervals. Conversion is complete when test drop and I soln produce only yellow stain on gypsum or porcelain plate. Report time of conversion in periods: <5 min, 5–7 min, etc. Time of conversion is not detd on coarsely ground malt.

(c) *Cooling and filtration.*—After 60 min, cool mash promptly (within 10–15 min) to prevailing room temp. Stop stirrers. Remove thermometers after adhering mash particles are rinsed into beaker with H<sub>2</sub>O. Remove each beaker with its stirrer from mashing app. Rinse mash particles adhering to stirrer into beaker with H<sub>2</sub>O. Dry outside of each beaker, taking care to remove moisture adhering to rim. Without delay, adjust wt of contents of mash beaker to 450.0±0.05 g by adding H<sub>2</sub>O.

Stir mash thoroly with glass rod, once when removing beakers from balance pan and again immediately before pouring mash onto filter. (Stirrings must be ≥5 min but <15 min apart.) While stirring cooled mash, take care to prevent splashing or spilling. Mix drops adhering to beaker wall into mash by rotary stirring with glass rod.

Pour entire contents of beaker into funnel provided with specified filter paper. Cover funnel with ca 20 cm diam. watch glass during entire filtration. Return first 100 mL filtrate to filter. When no more liq. is present above filter cake, discontinue filtration and remove receiving flask contg wort for later observations and tests. In case of slow running worts, stop filtration after 2 hr. In case of coarse ground malt mash, collect exactly 200±2 mL wort. When filtration is complete, mix wort in receiving flask thoroly by rotary motion. Speed of filtration is normal if filtration is complete (as defined above) within 1 hr after returning the 100 mL filtrate to filter bed; slow, if filtration takes longer. Observe degree of clarity and report as clear, slightly hazy, or hazy.

Remove ca 100 mL wort for detn of color. (Color is not detd on wort from coarsely ground malt.)

(d) *Specific gravity.*—Rinse empty pycnometer twice with ca 10 mL wort, and if Reischauer pycnometer is used, remove rinsings each time with emptying device. Fill with wort, place in H<sub>2</sub>O bath, and proceed as in **10.107(b)** or (c). Weigh filled pycnometer within 3 hr of completed filtration. Difference between this wt and that of empty pycnometer represents wort capacity of pycnometer at 20°. Calc. sp gr of wort to fifth decimal place, rounding off to 0.00005 or 0.00010, by dividing wt wort by wt H<sub>2</sub>O.

No calcn is made of sp gr *in vacuo*. If duplicate detns made by same analyst in different beakers differ by >2 units in fourth decimal place, repeat entire detn.

(e) *Extract.*—Det. ext yield of wort by ref. to sp gr values given in **52.009**, and calc. ext yield of malt by following formulas:

$$\text{Ext as-is basis} = P(800 + M)/(100 - P),$$

where  $P$  = g ext in 100 g wort (Plato, **52.009**); and  $M$  = % H<sub>2</sub>O in the malt.

$$\text{Ext dry basis} = (E \times 100)/(100 - M),$$

where  $E$  = ext as-is basis; and  $M$  = % H<sub>2</sub>O in the malt.

Report ext as-is basis and dry basis to nearest 0.1%.

#### 10.109 Extract in Caramel Malt—Official Final Action

Use mill for fine grinding, **10.106(a)**. Weigh ca 30.5 g caramel malt, grind, and adjust to 25±0.05 g, removing excess for moisture detn. Weigh ca 25.5 g malt of known moisture, ext, and color, and having Diastatic Power ≥100°; grind, and adjust to 25±0.05 g. Quant. transfer the 2 portions to mash beaker, mash, and det. sp gr as in **10.108(d)**. Det. moisture as in **10.103(b)** and **10.104**.

Calc. by following formulas:

$$\text{Total ext} = P \times (800 + M \text{ in 50 g malt} + M \text{ in 50 g caramel malt})/(100 - P),$$

where  $P$  = g ext in 100 g wort (Plato, **52.009**), and  $M$  = moisture (g).

$$\text{Ext in caramel malt} = (\text{total ext} - \text{ext in 50 g malt}) \times 100/50.$$

#### 10.110 Color in Caramel Malt—Official Final Action

Use mixed wort obtained for ext detn, dilg wort enough to make color reading ca 4.0 units. Det. color on dild wort as in **10.113** or **10.114**.

Calc. by following formula:

$$\text{Color of carmel malt} = 2[C \times (D + 1)] - \text{color of malt used for conversion},$$

where  $C$  = color reading on dild wort, and  $D$  = parts of H<sub>2</sub>O to dil. one part of wort.

Report dild used for making color reading. Report color to nearest whole number.

#### 10.111 Color in Black Malt—Official Final Action

Use mill for fine grinding, **10.106(a)**. As precautionary measure grind small amt of sample to be analyzed and clean out mill. For detn weigh 5.5 g, grind, and collect all particles by careful brushing of mill.

Weigh 5.00 g on anal. balance, transfer to 600 mL beaker, add 400 mL H<sub>2</sub>O at room temp., and heat to bp in ≥15 but <20 min. Boil gently exactly 5 min, cool to room temp., and without delay transfer to 500 mL vol. flask; dil. to vol. with H<sub>2</sub>O, mix, and filter thru 32 cm fluted paper. Pipet 10 mL filtrate into 100 mL vol. flask, dil. to vol. with H<sub>2</sub>O, and mix.

Det. color of dild wort as in **10.113** or **10.114**. Calc. color found for this filtrate to same concn of materials used for regular malt mash (12.5 g malt to 100 mL H<sub>2</sub>O) by formula:

$$\text{Color of black malt} = L \times 10 \times 12.5,$$

where  $L$  = color reading on dild filtrate. Report color to nearest whole number.

#### Color of Laboratory Wort (17) Official Final Action

##### 10.112 Preparation of Sample

Add 5 g Celite (anal. grade) to 100 mL filtered wort, **10.108(c)**, and mix. Let stand 5 min. Filter thru S&S No. 597 paper, or equiv. Return first 40 mL filtrate to filter. Det  $A$  on clear total filtrate.

##### 10.113 Spectrophotometric Method

Fill cell with clear filtrate and det.  $A$  of wort at 430 nm with spectrophtr, **10.002**.

Wort color =  $10 \times A_{430} \times$  correction to  $\frac{1}{2}$ " cell size.  
Report color to nearest 0.05 unit.

**10.114****Photometric Method**

Calibrate photometer, **10.006**, against spectrophtr as in **10.007**. Read clear filtrate in same size cell and at same wavelength as used in calibration. Multiply scale reading by av. calibration factor to give wort color. Report to nearest 0.05 unit.

**10.115 Protein—Official Final Action**

Weigh 1.4 g finely ground malt, **10.108**, and proceed as in **2.057**.  $\%N \times 6.25 = \% \text{ protein}$ .

**10.116 Wort Nitrogen—Official Final Action**

Using 25 mL laboratory wort, **10.108(c)**, det. N as in **10.045**. Calc. as wort N in terms of % malt (dry basis) as follows:

Wort N (% malt, dry basis) =  $(\text{mL } 0.1N \text{ H}_2\text{SO}_4 - \text{mL } 0.1N \text{ NaOH}) \times 0.0056 \times \% \text{ malt ext (dry basis)} / (^\circ\text{Plato of wort} \times \text{sp gr of wort})$ .

Report to second decimal place.

**Diastatic Power (18)—Official Final Action****10.117****Preparation of Glassware**

Wash all glassware with chromic acid cleaning soln, rinse with tap H<sub>2</sub>O  $\geq 4$  times, and finally rinse with H<sub>2</sub>O at least twice. Thoroughly dry digestion flasks. (*Caution:* Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>-H<sub>2</sub>SO<sub>4</sub> can cause severe burns. See **51.023** and **51.030**.)

**10.118****Reagents**

(a) *Acetate buffer soln.*—Dissolve 68 g NaOAc.3H<sub>2</sub>O in 500 mL 1N HOAc and dil. to 1 L with H<sub>2</sub>O.

(b) *Fehling soln.*—Stdze as in **31.035–31.036**. Check soln from time to time by detg its oxidizing value against std soln of invert sugar, **31.034(c)**, as in **31.035**.

(c) *Alkaline ferricyanide soln.*—0.05N. Dissolve 16.5 g dry K<sub>3</sub>Fe(CN)<sub>6</sub> and 22 g anhyd. Na<sub>2</sub>CO<sub>3</sub> in H<sub>2</sub>O, and dil. to 1 L with H<sub>2</sub>O. Soln keeps its strength for long period if stored in dark glass bottle in dark.

(d) *Sodium thiosulfate std soln.*—0.05N. Prep. daily by dilg 0.1N soln, **50.037–50.038**. Check Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> against K<sub>3</sub>Fe(CN)<sub>6</sub> soln as follows: To 10 mL K<sub>3</sub>Fe(CN)<sub>6</sub> soln add 25 mL HOAc reagent, 1 mL 50% KI soln, and 2 mL sol. starch indicator. Titr. with the Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. (Exactly 10 mL Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln should completely discharge blue starch-I color. Adjust if necessary.)

(e) *Acetic acid reagent.*—200 mL HOAc, 70 g KCl, and 20 g ZnSO<sub>4</sub>.7H<sub>2</sub>O/L.

(f) *Potassium iodide soln.*—50%. Dissolve 50 g KI in H<sub>2</sub>O, add 1 drop NaOH soln (1+1), and dil. to 100 mL with H<sub>2</sub>O. (Adding NaOH soln substantially delays deterioration of soln, with liberation of I, on standing; soln must be colorless.)

(g) *Starch soln.*—Have final concn of 2 g sol. starch (weighed on dry basis) in 100 mL soln. Use sol. starch, according to Lintner, special for diastatic power detn, with solubility at least 1:50 in hot H<sub>2</sub>O, that contains no dextrans, contains <0.75% reducing substances calcd as maltose, and has moisture content of 10–12%. Freshly made 2% soln must have pH of 4.5–5.5 without adjustment with buffer. Subsequent batches of starch, when tested on a malt of ca 100° Diastatic Power (dry basis) having other characteristics as specified under detn of ext in malt, must show variation  $\leq \pm 3^\circ$  Diastatic Power from value obtained by using original starch in parallel detn. Test addnl batches of starch, when purchased, in parallel with starch in use. Permit no variation  $> \pm 3^\circ$  Diastatic Power. In no case may

cumulative correction as referred to original starch, approved above, amt to  $> 5^\circ$  Diastatic Power. (Starch meeting these specifications is available from ASBC, 3340 Pilot Knob Rd, St. Paul, MN 55121.)

Macerate starch with just enough cold freshly distd H<sub>2</sub>O to form smooth, thin paste ( $\leq 5\%$  of final vol.). Pour, with const stirring, into boiling freshly distd H<sub>2</sub>O representing  $\geq$  ca 75% of final vol. of starch soln, at such rate that boiling does not cease. Continue boiling 2 min after thin paste is completely added. Quickly add to beaker addnl 10% of final vol. of cold, freshly distd H<sub>2</sub>O and quant. transfer mixt. to g-s vol. flask; mix by inverting flask, wash down neck of flask, and cool to 20° before adding buffer soln. Add 2 mL buffer soln for each 100 mL of final vol. of starch soln and dil. to vol. Mix again by inverting flask and keep tightly stoppered at 20° until used.

(h) *Soluble starch indicator.*—1% sol. starch in 30% NaCl soln. Prep. sol. starch suspension and pour slowly into boiling H<sub>2</sub>O. Add NaCl and dil. to vol. (Soln should be transparent and colorless.)

**10.119****Determination**

Grind sep.  $\leq 25.5$  g malt as in **10.108**. Collect finely ground malt in mash beaker, carefully brushing in malt particles remaining in mill. Without delay, adjust wt contents to  $25 \pm 0.05$  g. Transfer quant. to container (ca 1 L) in which infusion is to be made. Add 500 mL 0.5% NaCl soln at 20° and close container. Let infusion stand 2.5 hr at  $20 \pm 0.2^\circ$  and agitate by rotating at 20 min intervals. Take care that in agitation of malt suspension min. amt of grist is left adhering to inner surface of flask above level of the H<sub>2</sub>O. (Do not invert flask to mix; gentle whirling of contents without splashing on sides of container is sufficient.) Filter infusion by transferring entire charge to 30–32 cm fluted filter (S&S 588, or equiv.) in 185 mm funnel. Return first 50 mL filtrate to filter. Collect filtrate for 3 hr after H<sub>2</sub>O and ground malt were first mixed. Prevent evapn during filtration as far as possible by placing watch glass over funnel and some suitable cover around stem of funnel, resting on neck of receiver.

Immediately dil. 20 mL of this infusion to 100 mL with 0.5% NaCl soln at 20°, transfer 10 mL dild infusion to 250 mL vol. flask, and bring to 20°. Add 200 mL buffered starch soln from fast-flowing pipet, all at 20°. Mix soln by rotating flask during addn. Keep "starch infusion" mixt. at  $20 \pm 0.1^\circ$  exactly 30 min, timed on stop-watch from time addn of starch was begun. Rapidly add 20 mL 0.5N NaOH and mix well by whirling flask. Dil. to vol. at 20° and mix thoroly.

Det. reducing power by (a) Fehling soln modification, or (b) ferricyanide modification:

(a) *Fehling soln modification.*—Boil 10 mL Fehling soln and 10 mL H<sub>2</sub>O in 200 mL erlenmeyer. (For heating soln, elec. plate is preferable to gas flame.) Add, from buret, ca  $\frac{2}{3}$  of amt of above digested starch soln probably required and boil 15–20 sec, rotating constantly. Remove from heat. If still decidedly blue, add more soln, boil ca 10 sec, and again observe color. When blue is almost discharged, and after soln boils gently ca 2 min, add 3 drops 1% aq. methylene blue soln. Continue boiling and add more soln until 0.1 mL, or even 1 drop, upon boiling, discharges blue. (Color becomes violet-lavender as end point nears.)

Repeat titrn, adding at once almost whole amt of digested starch required, and proceed to end point as directed. Designate vol. of digested starch soln required to reach end point in this second titrn as V. Interrupt boiling as little as possible after indicator is added, so that flask remains filled with steam, preventing much access of air. (Upon cooling, blue usually returns.)

Prep. blank by processing exactly as in par. 2, except add the 0.5*N* NaOH to malt infusion before adding starch soln. To 10 mL Fehling soln and 10 mL H<sub>2</sub>O add a vol. of this blank soln equal to final vol. of digested starch soln required in above detn. Boil and again det. end point as in detn. Designate vol. of digested starch soln used as *B*.

(b) *Ferricyanide modification*.—Pipet 5 mL dild digested starch soln into 125 mL erlenmeyer. Pipet exactly 10 mL K<sub>3</sub>Fe(CN)<sub>6</sub> soln into soln, and immerse flask in vigorously boiling H<sub>2</sub>O bath. Have surface of liq. in flask 3–4 cm below surface of boiling H<sub>2</sub>O. Let flask remain in boiling H<sub>2</sub>O bath *exactly* 20 min; then cool under running H<sub>2</sub>O, and add 25 mL HOAc reagent with thoro mixing. Add 1 mL KI soln, followed by 2 mL sol. starch indicator, 10.118(h), and mix thoroly. Titr. with 0.05*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> to complete disappearance of blue (10 mL buret is recommended). Designate mL 0.05*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> used as *V*.

Prep. blank by proceeding exactly as in par. 2, except add the 0.5*N* NaOH to malt infusion before adding starch soln. Det. reducing power of blank as in preceding par. Designate mL 0.05*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> used for blank as *B*.

#### 10.120

#### Calculation of Diastatic Power

(a) *Fehling soln modification*.—Degrees Diastatic Power as-is basis =  $(5000/V) \times (B/V)$ ;

$$^{\circ}\text{Diastatic Power dry basis} = (^{\circ}\text{Diastatic Power as-is basis} \times 100)/(100 - M),$$

where *V* and *B* have same meaning as in 10.119(a), and *M* = % moisture.

In above formula, 5000/*V* is apparent  $^{\circ}$ Diastatic Power, which must be modified by fraction representing ratio of blank titrn to original titrn, which measures influence of starch in detn.

Report  $^{\circ}$ Diastatic Power as-is and dry basis to nearest whole number.

(b) *Ferricyanide modification*.— $^{\circ}$ Diastatic Power, as-is =  $(B - V) \times 23$ , where *V* and *B* have same meaning as in 10.119(b). Calc. dry basis from this as in (a) and report to nearest whole number.

When conditions given in method are followed, net vol. of ferricyanide, after correcting for blank,  $\times 23 = ^{\circ}$ Diastatic Power as-is basis.

#### Alpha-Amylase (19)—Official Final Action

#### 10.121

#### Reagents

(a) *Special starch*.—Use sol. Lintner starch, special for Diastatic Power detn, 10.118(g).

(b) *Beta-amylase*.—Use special  $\beta$ -amylase powder free from  $\alpha$ -amylase, made by Wallerstein Co. (Travenol Laboratories, Inc., Morton Grove, IL 60053). This prepn has been stdzd to 2000 $^{\circ}$  and should comply with following specifications: At addn level used, variation is  $\leq 5\%$  in dextrinization of std malt infusion when 1 and 3 day old substrates are compared. Further, substrate prepd by adding twice the level of  $\beta$ -amylase indicated must deviate by  $\leq 5\%$  from that prepd with recommended level after 24 hr standing. Store powder in tightly closed bottle in refrigerator. To avoid moisture condensation on cold enzyme prepn, let bottle warm to room temp. before opening.

(c) *Stock iodine soln*.—Dissolve 5.50 g I crystals (ACS) and 11.0 g KI in H<sub>2</sub>O, and dil. to 250 mL with H<sub>2</sub>O. Store in dark bottle and make fresh soln monthly.

(d) *Dilute iodine soln*.—Dissolve 20.0 g KI in H<sub>2</sub>O, add 2.00 mL of the stock I soln, and dil. to 500 mL with H<sub>2</sub>O. Series of 13  $\times$  100 mm test tubes contg 5 mL dil. I soln must be made up beforehand and adjusted to 20 $^{\circ}$  in readiness for testing. All-glass

automatic pipet such as the Machlett type is recommended for rapidly dispensing this soln.

(e) *Buffer soln*.—Dissolve 120 mL HOAc and 164 g anhyd. NaOAc in H<sub>2</sub>O, and dil. to 1 L.

(f) *Sodium chloride soln*.—0.5%. Dissolve 5 g reagent NaCl in 1 L H<sub>2</sub>O. This soln need not be made up in vol. flask.

(g) *Buffered limit-dextrin (alpha-amylodextrin) substrate*.—Prep. suspension of 10.00 g (dry wt) sol. starch, 10.118(g), in cold H<sub>2</sub>O and pour slowly into boiling H<sub>2</sub>O. Boil with stirring 1–2 min, cool, and add 25 mL buffer soln and 250 mg  $\beta$ -amylase dissolved in small amt H<sub>2</sub>O. Dil. to 500 mL with H<sub>2</sub>O, sat. with toluene, and store at ca 20 $^{\circ}$  for  $\geq 18$  hr but  $\leq 72$  hr before use.

#### 10.122

#### Apparatus

(a) *Constant temperature bath*.—Set at 20 $\pm$ 0.05 $^{\circ}$ .

(b) *Reference color std*.—Use special Alpha-Amylase Color Disk (Cat. No. 620S-5) made by Hellige Inc., 877 Stewart Ave., Garden City, NY 11530.

(c) *Comparator*.—Use either std Hellige comparator (Cat. No. 607-A13) or pocket comparator (Cat. No. 605-HT) with prism attachment (Cat. No. 605-AHT). Illuminate comparator with 100 watt frosted lamp mounted in such manner that direct rays from lamp do not shine in operator's eyes. Place lamp 15 cm (6") from rear opal glass of comparator. Slight differences in color discrimination between different operators are minimized by use of prism attachment, by maintaining 15–25 cm (6–10") reading distance between eye and comparator, and by experience gained with continued practice.

(d) *Comparison tubes*.—Use precision bore sq tubes with 13 mm viewing depth. Place tube filled with distd H<sub>2</sub>O behind color disk.

The  $\alpha$ -amylase color disk is correct only when used with specified 13 mm viewing depth. Precision bore sq tubes are specified to obviate need for individual calibration of test tubes and to ensure use of std viewing depth. The 13 mm precision sq tubes are supplied as std equipment with Hellige comparator and are also used with Coleman Universal spectrophtr. They may be secured from either Hellige Inc., distributors of Coleman instrument, or Fischer & Porter Co.

#### 10.123

#### Determination

(a) *Preparation of malt infusion*.—Ext 25 $\pm$ 0.05 g finely ground malt exactly as in 10.119, par. 1, using 500 mL 0.5% NaCl soln. Dil. 20 mL malt infusion to 100 mL with 0.5% NaCl soln at 20 $^{\circ}$ .

(b) *Dextrinization*.—Transfer 20.0 mL substrate soln at 20 $^{\circ}$  to 50 mL erlenmeyer, add 5 mL 0.5% NaCl soln, and again adjust to 20 $^{\circ}$ . Add 5 mL dild malt infusion at 20 $^{\circ}$ , blowing it in and counting time from instant first of the dild malt infusion reaches starch substrate in flask. After 10 min reaction time, add 1 mL hydrolyzing mixt. to 5 mL dil. I soln at 20 $^{\circ}$ , shake, pour into 13 mm sq tube, and compare with  $\alpha$ -amylase color disk in comparator. At appropriate intervals remove addnl 1 mL aliquots hydrolyzing mixt., add to dil. I soln, mix, and compare with color disk until  $\alpha$ -amylase color is reached. Take care to keep tubes contg reaction mixt. plus I from changing temp. while comparing colors. If color comparisons are made immediately after addn of reaction mixt. to I, there will be essentially no temp. change and no change in color.

During initial stages of reaction, 1 mL sample need not be measured precisely before addn to dil. I soln. As end point approaches, make addn accurately with 1 mL pipet. (Use fast-flowing pipet such as 1 mL bacteriological pipet for withdrawing 1 mL aliquot.) Blow contents of pipet into I soln. Near end point, take readings every 0.5 min on the min or half min. In case two readings 0.5 min apart show that one is darker than  $\alpha$ -amylase

color disk and other is lighter, record end point at nearest 15 sec. Shake out 13 mm sq tube used for color comparison between successive readings.

For accuracy and convenience, it is desirable that dextrinization times fall between 10 and 30 min. With malts of low  $\alpha$ -amylase activity it may be necessary to use 10 mL dild infusion. In this case, do not add 5 mL NaCl soln. Final vol. of reaction mixt. should always be 30 mL.

#### 10.124 Calculation of Alpha-Amylase Activity

From time interval in min necessary for dextrinization,  $T$ , and wt malt in g represented by infusion aliquot taken,  $W$ , calc.  $\alpha$ -amylase dextrinizing units (DU). An  $\alpha$ -amylase unit is defined as amt of  $\alpha$ -amylase which will dextrinize sol. starch in presence of excess of  $\beta$ -amylase at rate of 1 g/hr at 20°.

$$20^{\circ} \text{ DU (as-is basis)} = 24/(W \times T);$$

$$20^{\circ} \text{ DU (dry basis)} = \text{DU (as-is)} \times 100/(100 - M);$$

where  $M$  = % moisture in sample, and 24 = wt starch used (0.4 g) multiplied by 1 hr (60 min).

Example:  $W = 0.05$  g;  $T = 20$  min;  $20^{\circ} \text{ DU (as-is)} = 24/(0.05 \times 20) = 24$ .

Report dextrinizing units to nearest 0.1 unit.

### CEREAL ADJUNCTS

#### 10.125 Sampling—Official Final Action

See 10.092.

#### 10.126 Preparation of Sample—Official Final Action

See 10.093.

#### 10.127 Physical Characteristics—Procedure

(a) *Accidental foreign particles*.—Before proceeding with laboratory detns remove any accidental foreign particles from sample. Report presence and amt.

(b) *Color*.—Spread suitable portion of sample evenly and observe against white background. Report as white, cream, yellow, buff, gray, brown.

(c) *Odor*.—Det. after shaking sample in closed container. Report as clean and normal, moldy, musty, rancid, or other foreign odor.

(d) *Husks, germs, and foreign seeds*.—Classify and report in %.

(e) *Mold*.—Det. by visual inspection and report as none, trace, considerable.

(f) *Weevils, larvae, etc.*—Det. presence or absence by visual inspection. Report as none, very few, few, considerable; indicate if alive or dead.

#### Assortment of Corn Grits (20) Official Final Action

#### 10.128

#### Apparatus

(a) *Sieve shaker*.—Such as Ro-Tap testing sieve shaker (W. S. Tyler Co., 8200 Tyler Blvd, Mentor, OH 44060).

(b) *Nested set of sieves and pans*.—8" sieve diam., Nos. 20, 30, 40, 60, 100, or other similar series.

#### 10.129

#### Determination

Accurately weigh ca  $50 \pm 0.1$  g of well mixed, representative sample of grits, 10.125–10.126. (To obtain representative sample <100 g, pass successively thru sample divider.) Transfer sample to top sieve of set of sieves with pan, assembled and fixed in

shaker, and shake 5 min. Weigh, to 0.1 g, grits particles remaining on and adhering to each of sieves, or caught in pan.

Calc. wt of each sieve fraction and pan fraction as % of sample wt. Report % of each fraction to 1 decimal place.

#### Moisture—Official Final Action

##### Air Oven Method (103–104°)

#### 10.130

See 10.102.

#### Apparatus

#### 10.131

#### Determination

Grind as in 10.108, fine grinding, and proceed as in 10.104.

#### Oil or Petroleum Ether Extract Official Final Action

#### 10.132

#### Reagent

*Petroleum ether*.—AOCS. Initial boiling temp., 35–38°; dry-flask end point, 52–60°;  $\geq 95\%$  distg at <54°, and  $\leq 60\%$  distg at <40°; sp gr at 60°F, 0.630–0.660; appearance, colorless; evapn residue,  $\leq 0.0011$  g/100 mL; doctor test, sweet; Cu strip corrosion test, noncorrosive; only trace of unsatd compds permitted; residue in distg flask, neut. to Me orange; blotter strip odor test, odorless within 12 min; aromatic compds, no nitrobenzene odor; saponification value, <1.0 mg KOH/100 mL.

Make distn test according to ASTM method D216-54 and make blank detn by evapg 250 mL with ca 0.25 g stearin or other hard fat (previously brought to const wt by heating) and drying as in actual detn. Blank must be  $\leq 3$  mg.

#### 10.133

#### Determination

(Caution: See 51.011, 51.039, and 51.073.)

Accurately weigh 5–10 g sample ground as in 10.108. Without previous drying, ext in Soxhlet or other suitable extractor with pet ether for  $\leq 6$  hr. Filter ext thru small, hardened paper into weighed vessel, washing paper finally with small portion of hot fresh solv. Distil or evap. solv. at temp.  $\leq 100^{\circ}$  and dry vessel contg residue in air oven 1 hr at 100–105°. Report as % oil to second decimal place.

#### Extract—Official Final Action

#### 10.134

#### Apparatus

Same as in 10.106 except that mill may be of any suitable type.

#### 10.135

#### Standardization

*Setting of mill*.—Use sample of rice or grits with moisture content  $\leq 12\%$ . Grind enough sample to obtain  $\geq 51$  g ground portion. Det. fineness of grinding as in 10.107(a). Fine grinding of rice should show  $40 \pm 2.5$  g ( $= 80 \pm 5\%$ ) and grits  $35 \pm 2.5$  g ( $= 70 \pm 5\%$ ) of ground portion passing thru std sieve.

#### 10.136

#### Determination

Grind enough sample to obtain  $\geq 21$  g. Grind ca 31 g malt made mainly from 6-rowed barley of Manchurian type, conversion time  $\leq 7$  min, Diastatic Power 100–120°. Det. ext of malt simultaneously with that of the cereal.

Mash in  $20 \pm 0.05$  g sample (with exception of flaked corn and flaked rice) and  $5 \pm 0.05$  g ground malt with 200 mL  $H_2O$  at 46°. Mix well with glass rod, place on wire gauze over flame, and bring to bp in  $\geq 10$  min but  $\leq 15$  min, stirring constantly. Boil grits and rice gently 30 min, and refined grits 10 min, avoiding

burning, spattering, and excessive frothing. During boiling, stir mash and keep vol. const by adding boiling H<sub>2</sub>O every 15 min. After boiling, cool to 46° and add 25±0.05 g remaining ground malt. When ext is detd on flaked corn or flaked rice, do not boil, but mash in 20 g unground sample and 30 g ground malt with 200 mL H<sub>2</sub>O at 46°. Mix well to prevent formation of lumps, rinse inner walls of beaker, promptly place mash beakers in mashing app. contg H<sub>2</sub>O previously heated to 46°, and set stirrers in motion. Hold 30 min at 45° from time mash beakers were placed in app. Raise mash temp. 1°/min until 70° is reached. Add 100 mL H<sub>2</sub>O, previously heated to 70–71°, and hold mash 60 min at 70°. (All temps refer to mash, not H<sub>2</sub>O bath temp. Temp. deviation during mashing should be ≤0.5°.)

To test conversion, transfer drop mash to one cavity of porcelain plate and add drop 0.02*N* I soln, 10.105(b); conversion is complete when test drop and I soln give yellow soln. Report time of conversion in periods: <15 min, 15–30, 30–45, 45–60, incomplete at 60 min. Cool, filter as in 10.108(c), and det. sp gr and corresponding ext as in 10.108(d) and (e).

**10.137****Calculation**

Total ext =  $P \times (800 + M \text{ in } 60 \text{ g malt} + M \text{ in } 40 \text{ g sample}) / (100 - P)$ ,

where  $P$  = ext from Plato's table, 52.009, and  $M$  = % moisture.

Ext in sample = (total ext – ext in 60 g malt) × 100/40.

**Enzyme Method for Corn Grits (21)**  
**Official Final Action**

**10.138****Reagents**

(a) *Enzyme mixture*.—Alpha-amylase and malt diastase, "Special for Analytical Purposes" (Wallerstein Co., Travenol Laboratories, Inc., Morton Grove, IL 60053). Mix in proportions 1+4.

(b) *Iodine soln*.—0.02*N*. See 10.105(b).

**10.139****Apparatus**

(a) *Wiley or other mill*.—For fine grinding, equipped with 1 mm (openings) sieve (No. 18 or similar).

(b) *Other apparatus*.—Same as for 10.106, except (a), (b), and (e).

**10.140****Determination**

*Preparation of corn grits for mashing*.—Grind enough grits to yield 36 g grist passing thru 1 mm sieve openings (collect 72 g if detn is to be made in duplicate). Prep. addnl 24 g if single detns of moisture, oil, protein, and ash are to be made.

*Mashing procedure*.—Weigh, into mash beaker, 35 ±0.05 g ground corn grits and 0.5±0.05 g enzyme mixt. Mix dry ingredients, add 200 mL H<sub>2</sub>O at 46°, and mix well with glass rod. Mark liq. level on beaker wall. Place mash beaker on wire gauze over flame. With const stirring, bring contents to bp within 15 min and boil gently 30 min, avoiding burning, spattering, and excessive frothing. During boiling, dil. contents to original vol. every 15 min with boiling H<sub>2</sub>O.

Cool to 46° and add 2.5±0.05 g enzyme mixt. Mix well to disperse mixt. thoroly and to prevent formation of lumps. Wash down inside walls of beaker with rubber policeman and little H<sub>2</sub>O.

Promptly place mash beaker in mashing app. contg H<sub>2</sub>O previously heated to 46°, insert thermometer in beaker, and start stirrers. Starting at 45°, raise mash temp. 1°/min to 70°. Add 100 mL H<sub>2</sub>O previously heated to 70–71°. Hold mash 30 min at 70°. Do not let temp. deviations during mashing exceed 0.5°. (All temps are *mash* temps, not H<sub>2</sub>O bath temps.)

*Conversion*.—Using ca 3 mm diam. glass rod, transfer 1 drop mash to cavity of porcelain spot test plate and test with 1 drop 0.02*N* I. Judge color exactly 2 min after addn. Make spot test every 15 min after mash temp. has reached 70°. Conversion is complete when I produces only yellow color with mash. Report conversion time in periods of <15 min, 15–30, or incomplete in 30 min.

*Cooling and filtration*.—After 30 min at 70°, cool and filter mash as in 10.108(c).

*Determination of specific gravity*.—See 10.108(d). Obtain Plato value of ext corresponding to its sp gr from 52.009.

*Enzyme extract blank*.—Det. ext value of enzyme reagent by carrying 3.0 g enzyme mixt., without ground corn grits, thru mashing operation as above. Omit conversion tests. Cool, filter, and det. Plato value of filtrate from its sp gr as above.

Make single ext detn for each lot of enzyme mixt.

**10.141****Calculations**

% Ext in corn grits, as-is,

$$= \left[ \frac{Pg(830 + 0.7M - 2D)}{100 - Pe} - EE \right] \times \frac{100}{70}$$

GE, dry basis, % = GE, as-is × 100/(100 –  $M$ ),

where  $M$  = % moisture in grits sample,  $D$  = g enzyme reagent mixt. used,  $Pe$  = g ext in 100 g enzyme blank filtrate (°Plato),  $Pg$  = g ext in 100 g grits mash filtrate (°Plato), and  $EE$  = ext added with enzyme reagents mixt. =  $Pe(900 - 2D)/(100 - Pe)$ .

Report % ext in corn grits to nearest 0.1%.

**10.142 Crude Fat or Ether Extract—Official Final Action**

See 7.056.

**10.143 Protein—Official Final Action**

See 2.057. Multiply results by 6.25.

**10.144 Ash—Official Final Action**

See 14.006.

**10.145 Crude Fiber—Official Final Action**

See 7.061–7.065.

**HOPS****10.146 Sampling—Official Final Action**

(Oregon sampler, Bates divider, and sampling procedure are described in "Hop Inspection Manual Covering the Determination of Leaves and Stems and Seeds in Hops," Instruction No. 918(GR)-1, available from Federal Grain Inspection Service, Standardization Div., US Dept. of Agriculture, 1400 Independence Ave SW, Washington, DC 20250.)

(a) *Unpressed hops*.—Draw equal portions from 5 or 10 different parts of heap, from surface as well as from different depths, until ca 200 g is obtained. Place sample in suitable container such as tin can having screw- or friction-type cover, moisture-proof plastic bags, or jars.

(b) *Baled hops*.—Use Oregon sampling device or sharp knife to cut 200 g samples from ≥10% of bales in shipment <100 bales and sq root of number of bales if >100, avoiding sampling at press seam. Place each bale sample in sep. container. (If chem. tests are to be made, store in tin cans having friction or screw tops, not cartons, paper bags, wrapping paper, or wooden boxes.) Take sufficient equal amt from each bale sample so that total of 100 g is combined in one composite sample. (Use of Bates divider gives most accurate results.)

**10.147 Physical Examination (22)—Official Final Action**

(a) *Leaves and stems*.—With tweezers or forceps, pick out stems and leaves from  $20 \pm 0.01$  g sample. Det. wt leaves and stems to 1 decimal place. Use remainder of sample for seed detn, if required.

(b) *Size and condition of cones*.—Report size according to following classification:

	Length, inches
Large	2¼–3
Medium	1¼–2
Small	¾–1

Report condition of cones as unbroken, partly broken, much broken.

(c) *Lupulin*.—Break 10 cones into longitudinal halves and examine lupulin grains thereby exposed in good light, preferably daylight, as to amt, color, and condition. Report amt as plentiful, fairly plentiful, scarce. Report color as lemon-yellow, orange-yellow, brownish. Report condition as sticky, fairly sticky, not sticky.

(d) *Seeds*.—Dry portion remaining from leaf and stem detn, or sep. 20 g sample, in oven 3–6 hr at  $>100^\circ$  or 2 hr at  $114\text{--}116^\circ$  (long enough to eliminate stickiness). (If rapid drying is necessary, place sample in 60 cm (2') sq muslin cloth, immerse in bowl of MeOH or trichloroethylene 1 min, press out excess liq. by hand, using rubber gloves for protection, and spread cloth contg hops on screen to dry in air or over steam radiator. *Caution: See 51.040.*)

Fold portions of the dried hops in dry sq of muslin and rub between hands to crush petals completely; then empty finely pulverized material onto  $4 \times 20$  wire mesh screen to sep. petal substance. Continue this process until portion left on screen consists mainly of seeds and rachillae; sep. these by rolling seeds off large sheet of sandpaper into tared dish, weigh, and report % by wt to 1 decimal place.

(e) *Color and luster*.—Det. color and luster on whole cones and refer findings to predominating character of sample. Report color as greenish-yellow, yellowish-green, pale green, olive-green, dark green. Describe presence of amts of differently colored cones as: small, medium, or large amt of \_\_\_\_\_ cones present, using appropriate color terminology, such as brownish, reddish, etc.

(f) *Aroma*.—Rub several cones between hands. Report odor as aromatic, mildly aromatic, abnormal. Use term flowery to describe exceptionally fine aroma. Use proper designations, such as musty, cheesy, etc., to describe abnormal odors.

**10.148 Aphids—Official First Action**

*See 44.009–44.011.*

**10.149 Preparation of Sample for Chemical Analysis  
Official Final Action**

Grind hop samples immediately before analysis. Let samples stored in refrigerator come to room temp. before grinding.

Grind 50–75 g sample in No. 2 or 72 Universal food chopper, using 12-tooth cutter. Discard first 5 or 10 g. Place polyethylene bag over discharge of chopper so that hops pass directly into bag. Pass hops evenly and slowly thru grinder, taking care to avoid choking orifices so as to prevent undue heating of hops. Thoroughly mix ground portion into homogeneous mass and store in air-tight container in cool, dark place. (In some cases definite amts of ground portions from several samples may be mixed together, and analyses made, in duplicate, on mixed portion.)

For accurate results in analysis for resins, detn must be completed on same day as grinding, since resins are subject to oxidn.

**10.150 Moisture—Official Final Action**

Use one of following methods which are listed in order of accuracy:

- (1) Me cyclohexane or *n*-heptane distn method with 10.00 g sample, **7.004–7.005**.
- (2) Vac. drying 3 hr at  $60^\circ$  at 560–580 mm (22–23") Hg, **7.003**.
- (3) Drying 1 hr at  $103\text{--}104^\circ$ , **10.102–10.104**.

For (2) and (3) use 2.5 g ground sample in 55 mm weighing bottle or Al dish, or 5 g ground sample in 70 mm dish. (Amt of hops and dimensions of dish used are important for accurate results.) Report results in % to 1 decimal place, and state method used.

**Alpha and Beta Acids (23)—Official Final Action****10.151****Reagents**

(a) *Methanol*.—Reagent grade. *A* in 1 cm cell  $<0.060$  at 275 nm against  $\text{H}_2\text{O}$ .

(b) *Alkaline methanol*.—Add 0.2 mL 6*N* NaOH to 100 mL MeOH, (a). Soln must be fresh.

(c) *Benzene*.—Reagent grade. *A* in 1 cm cell  $<0.110$  against  $\text{H}_2\text{O}$  at 275 nm when 1 mL is dild to 100 mL with reagent (b). (*Caution: See 51.018, 51.040, and 51.045.*)

**10.152****Apparatus**

*Spectrophotometer*.—For UV use with 1 cm cells. Calibrate with soln contg 0.0400 g  $\text{K}_2\text{CrO}_4$ /L of 0.05*N* KOH. *See* Definitions of Terms and Explanatory Notes, item (23).

**10.153****Determination**

Weigh  $5 \pm 0.001$  g ground hops into 250 mL g-s bottle or flat-bottom flask. With pipet, add 100 mL benzene, (c). Grease stopper with *Dow Corning high vac. silicone stopcock grease* and stopper tightly. Weigh bottle or flask to nearest 0.1 g and record. Shake vigorously 30 min on mech. shaker and reweigh. If wt loss is  $>0.2\text{--}0.3$  g, start new detn. Let flask stand until supernate clears.

Dil. appropriate aliquot of benzene ext with alk. MeOH, (b), so that *A* falls within most accurate range of instrument used. For hops contg ca 8% total *alpha* and *beta* acids, pipet 5 mL benzene ext into 50 mL vol. flask and dil. to vol. with alk. MeOH (*Diln I*); then dil. 4.00 mL *Diln I* to 50 mL with alk. MeOH (*Diln II*). For hops of high *alpha* and *beta* acid content, dil. 4.00 mL *Diln I* to 100 mL for *Diln II*.

Det. *A* of *Diln II* at 275, 325, and 355 nm, first setting instrument to 0 *A* with blank prepd by dilg 5 mL benzene, (c), with alk. MeOH in same sequence used for samples.

**10.154****Calculations**

(a) % *alpha* acids =  $d \times (-51.56A_{355} + 73.79A_{325} - 19.07A_{275})$ , where *d* = diln factor, and  $A_{355}$ ,  $A_{325}$ , and  $A_{275}$  = *A* of *Diln II* at resp. wavelengths. For diln sequence 5 to 50 mL, followed by second diln of 4 to 50 mL,

$$d = (50 \times 50 \times 100 \times 20) / (1000 \times 4 \times 5 \times 1000) = 0.25$$

(b) % *beta* acids =  $d \times (55.57A_{355} - 47.59A_{325} + 5.10A_{275})$ , where *d* and  $A_{355}$ ,  $A_{325}$ , and  $A_{275}$  have same values as in (a).

Report both *alpha* and *beta* acids to 1 decimal place.

## BREWING SUGARS AND SIRUPS

### 10.155 Color and Clarity—Official Final Action

(a) *Clarity*.—Observe degree of clarity of unfiltered "10% soln," **10.156(a)**. Report as clear, slightly hazy, or hazy.

(b) *Color*.—Free "10% soln," **10.156(a)**, from suspended matter and, if possible, from haze by filtration thru dry paper. Det. color as in **10.004**, **10.113**, or **10.114**. Report as color of "10% soln" to nearest 0.1 unit.

### 10.156 Extract—Official Final Action

(a) *Preparation of "10% soln."*—Accurately weigh ca 50 g well mixed representative sample, dissolve in warm H<sub>2</sub>O, transfer quant. to 500 mL vol. flask, and dil. to vol. at 20°. Mix thoroly.

(b) *Determination*.—With suitable pycnometer, det. sp gr of soln at 20/20°, as in **10.107(b)** or (c). Obtain corresponding ext from **52.009**. Calc. % ext in original sample, *E*, from following formula:

$$E = P \times B \times 500/W,$$

where *P* = ext of dild sample; *B* = sp gr of dild sample; and *W* = actual wt (ca 50 g) of sample taken. Report to 1 decimal place.

(c) *Degrees Baumé*.—Obtain degrees Baumé (Modulus 145) equiv. to ext of original sample, (b), from **52.009**.

### 10.157 Nonextract (Apparent Water) Official Final Action

Obtain by subtracting ext of original sample, **10.156(b)**, from 100.

### 10.158 Fermentable Extract (24)—Official Final Action

(a) *Regular fermentation method*.—Ferment 250 mL "10% soln" of sample, **10.156(a)**, with equiv. of 5 g washed, active brewers compressed yeast 48 hr at 15–25° or until fermentation is complete. In case of refined sugars and sirups, such as corn sirup, add to soln, before fermenting, 0.8 g K<sub>2</sub>HPO<sub>4</sub> crystals, 1 g NH<sub>4</sub>H<sub>2</sub>PO<sub>4</sub>, and 0.5 g dried yeast ext, stdzd for bacteriological culture media purposes, as nutrients. If such nutrient material needs to be added, redet. ext of the "10% soln" after adding nutrient material, but before adding yeast. Use fermentation flasks equipped with either H<sub>2</sub>O, Hg, or acid seals, and shake flasks several times a day during fermentation. When fermentation is complete, filter soln thru dry paper, refiltering first 20–30 mL filtrate. (Filtrate should be clear, but not necessarily brilliant.) Det. real ext in filtrate as in **10.021(a)**, after removal of alcohol.

Use following formulas for calcn:

$$\text{Fermentable ext (ext basis)} = (p - n) \times 100/P;$$

$$\text{Fermentable ext (as-is basis)} = (p - n) \times E/P;$$

where *P* = ext of "10% soln" before addn of any nutrients; *p* = ext of "10% soln" before fermentation; *n* = real ext of "10% soln" after fermentation; and *E* = ext of original sample, **10.156(b)**.

If nutrients have not been used (as in case of malt sirups), *p* = *P*, and will have been detd in **10.156(b)**, and no redetn before fermentation is required. Report to 1 decimal place.

(b) *Rapid fermentation method*.—Proceed as in (a), but for 250 mL "10% soln" of sample, **10.156(a)**, use equiv. of 32 g fresh compressed brewers yeast or liq. yeast that has been de-watered by suction on buchner (more precise results are obtained by washing yeast with "10% soln" of sample before final suction filtration). For refined sugars and sirups, use nutrients

as in (a). Ferment mixt. at room temp. (20–23°) and stir continuously with 4-blade glass stirrer (ca 5 cm diam.) at 100–120 rpm until fermentation is complete (4–5 hr). Keep stirring and time at min., as evapn can be important variable. Filter, det. real ext, and calc. as in (a).

Yeast autolysis can affect results by contributing solids to fermented liq. Effect may be checked by detg pH of fermented liq., its alcohol content, and calcd original gravity, **10.022**. If pH is high and original gravity is appreciably higher than ext of "10% soln" originally detd, yeast autolysis has probably occurred and detn should be repeated with fresh yeast.

### 10.159 Protein—Official Final Action

(a) Transfer 25 mL "10% soln," **10.156(a)**, to Kjeldahl digestion flask, and proceed as in **10.045**.

$$\begin{aligned} \text{\% protein (N} \times 6.25) \text{ in original as-is sample} \\ = 100 \times (\text{mL } 0.1N \text{ H}_2\text{SO}_4 - \text{mL } 0.1N \text{ NaOH}) \\ \times 0.0014 \times 6.25 \times 500 / (25 \times W), \end{aligned}$$

where *W* = actual wt sample used in prepg "10% soln." Report to 2 decimal places.

(b) Det. N as in **31.019**, and calc. protein, using factor N  $\times$  6.25.

### 10.160 Diastatic Power—Official Final Action

(Malt sirups only)

Transfer 10 mL "10% soln," **10.156(a)**, to 100 mL vol. flask and dil. to vol. at 20° with H<sub>2</sub>O. Transfer 10 mL "1% soln" so prepd to 250 mL vol. flask, bring to 20°, add 200 mL buffered starch soln at 20°, **10.118(g)**, and proceed as in **10.119**, last 4 sentences in second par., beginning "Mix soln ..." and ending "... mix thoroly." Follow Fehling soln modification, **10.119(a)**.

Calc. on as-is basis according to formula:

$$\text{°Diastatic Power (as-is basis)} = (5000 \times B \times 50) / (V \times V \times W),$$

where *V* = mL digested starch soln required to reach end point in detn; *B* = mL digested starch soln required to reach end point in blank; and *W* = wt sirup used to prep. "10% soln."

### 10.161 Iodine Reaction for Unconverted Starch Official Final Action

Use "10% soln," **10.156(a)**, and proceed as in **10.044**.

### 10.162 Acidity—Official Final Action

Transfer 100 mL "10% soln," **10.156(a)**, to suitable beaker or flask and proceed as in **10.033**, second par., or **10.034**, beginning "... titr. potentiometrically ..." Calc. and report results as follows (*W* = actual wt sample, in g, used to prep. "10% soln"):

(a) In terms of mL 1*N* NaOH/100 g original sample, as-is basis:

$$\text{Acidity} = \text{mL } 0.1N \text{ NaOH consumed} \times 500 / (10 \times W).$$

Report to 1 decimal place.

(b) In terms of "lactic acid" as % original sample, as-is basis:

$$\text{Acidity} = \text{mL } 0.1N \text{ NaOH consumed} \times 0.009 \times 500 / W.$$

Report to 2 decimal places.

### 10.163 Hydrogen-Ion Activity (pH)—Official Final Action

Using "10% soln," **10.156(a)**, proceed as in **10.035**.

### 10.164 Ash—Official Final Action

Proceed as in **31.012** or **31.013**.

**Total Reducing Sugars (25)—Official Final Action****10.165 Munson-Walker General Method**

Transfer 50 mL "10% soln," **10.156(a)**, to 250 mL vol. flask. Clarify, if necessary, with alumina cream or neut.  $\text{Pb}(\text{OAc})_2$  soln only (never basic  $\text{Pb}(\text{OAc})_2$ ), and dil. to vol. at 20° with  $\text{H}_2\text{O}$ . Mix thoroly and either centrf. or filter until clear. If  $\text{Pb}(\text{OAc})_2$  soln was used for clarification, remove excess Pb with dry  $\text{Na}_2\text{C}_2\text{O}_4$ . Filter, and det. reducing sugars on 10 mL aliquot as in **31.038–31.039**, **31.051**, or **31.060**. Calc. results in terms of invert sugar for invert sirups and sugars; glucose for corn sugars and sirups; and maltose for malt sirups. If character of sample is in doubt, express reducing sugars as glucose.

$$\% \text{ Reducing sugar, as-is} = 25M/W,$$

where  $M$  is mg sugar from appropriate column of **52.019**, and  $W$  is g sample used to prep. "10% soln."

**10.166 Lane-Eynon General Volumetric Method**

Dil. 50 mL soln, clarified as in **10.165**, to 100 mL and proceed as in **31.035–31.036**, **31.050**, or **31.059**, referring titer to **52.017** or **52.018**. Calc. results as in **10.165**.

**10.167 Glucose—Official Final Action**

To 5 mL aliquot of soln prepd as in **10.165**, add 15 mL  $\text{H}_2\text{O}$  and proceed as in **13.052** or **13.055**.

**10.168 Other Determinations**

See Chapter 31.

**WORT—OFFICIAL FINAL ACTION****10.169 Preparation of Sample**

Store 1 gal. wort 12–15 hr at 4–7°; then filter all but last portion of this sample at 4–7° thru paper of types specified in **10.106(f)**. If filtrate is not brilliant after first filtration, return to filter, but do not use filter-aid. (Some worts cannot be filtered brilliantly clear.) To prevent spoiling, keep sample in refrigerator, and if necessary, place in beer bottles and pasteurize. Mix sample well to insure uniformity before removing portion for analysis.

**10.170 Specific Gravity**

Proceed as in **10.016** or **10.108(d)**. Report to 5 decimal places.

**10.171 Viscosity (3)**

Det. sp gr as in **10.170**. Proceed as in **10.017–10.019**, beginning, "Clean viscometer . . ." and substituting "wort" for "beer."

**10.172 Original Extract or Original Gravity**

From **52.009**, find ext corresponding to sp gr detd at 20/20°, **10.170**. Report as °Plato (g/100 g) to 2 decimal places.

**10.173 Fermentable Extract**

(a) *Regular method*.—Ferment 250 mL wort with equiv. of 5 g washed, active brewers compressed yeast 48 hr at 15–25°, or until fermentation is complete. Use either  $\text{H}_2\text{O}$ , Hg, or acid seal to prevent evapn. Filter soln and det. real ext in filtrate as in **10.021(a)**, after removal of alcohol.

Calc. % by wt of fermentable ext as in **10.158**. Report to 2 decimal places.

Calc. also real degree of fermentation as in **10.028**. Report to 1 decimal place.

(b) *Rapid method*.—(Dets fermentability of worts contg up to ca 14% ext in 4–5 hr within 0.3–0.1% of attenuation limit.)

To 200 mL wort in 400–600 mL glass beaker add 32 g fresh, compressed, washed brewers lager yeast or liq. yeast that has been dewatered by suction on buchner (more precise results are obtained by washing yeast with wort to be pitched before final suction filtration). Keep mixt. at room temp. (20–23°) and stir continuously with glass stirrer until fermentation is complete (4–5 hr). Filter mixt. thru ordinary filter paper, refiltering first 20–30 mL filtrate. (Filtrate should be clear, but not necessarily brilliant.) As evapn can be important variable, keep stirring and time at min. Four-blade glass stirrer (ca 5 cm diam.) operating at 100–120 rpm is satisfactory. Abnormal effects due to autolysis are likely to be indicated by too high pH of final beer and high calcd original gravity compared to actual original gravity. See **10.158(b)**. Det. real ext and calc. as in (a).

**10.174 Iodine Reaction**

See **10.044**.

**10.175 Total Acidity**

See **10.033** or **10.034**.

**10.176 Hydrogen-Ion Activity (pH)**

See **10.035**.

**10.177 Color**

Prep. sample as in **10.169**. If prepd wort has developed haze or sediment that would interfere with detn, clarify by centrfg or filtering without use of filter-aid. Indicate such clarification in report. Det. depth of color of prepd sample as in **10.113** or **10.114**.

**10.178 Protein**

Prep. sample as in **10.169**. If prepd sample shows sediment, mix thoroly to ensure uniform distribution of sediment before removing portion for analysis. To det. protein in the brilliant wort (free from any haze or sediment), reclarify prepd sample by centrfg or filtering without use of filter-aid. Indicate such clarification in report.

Pipet 25 mL prepd sample, measured at 20°, into 800 mL Kjeldahl flask and proceed as in **10.045**.

**Free Amino Nitrogen in Wort (26)****10.179****Reagents**

(a) *Ninhydrin color reagent*.—Dissolve 10.0 g  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ , 6.0 g  $\text{KH}_2\text{PO}_4$ , 0.5 g 1,2,3-indantrione,  $\text{H}_2\text{O}$ , and 0.3 g fructose in  $\text{H}_2\text{O}$ , and dil. to 100 mL. pH should be 6.6–6.8. Reagent is stable 2 weeks if kept cold in amber bottle.

(b) *Dilution soln*.—Dissolve 2 g  $\text{KIO}_3$  in 600 mL  $\text{H}_2\text{O}$ , and add 400 mL alcohol. Store at 5°.

(c) *Glycine std solns*.—(1) *Stock soln*.—Dissolve 107.2 mg glycine in  $\text{H}_2\text{O}$ , and dil. to 100 mL. Store at 0°. (2) *Working soln*.—2 mg amino N/L. Dil. 1.0 mL stock soln to 100 mL with  $\text{H}_2\text{O}$ .

**10.180****Determination**

(a) *Wort*.—Prep. sample as in **10.169**. Dil. 1.0 mL to 100 mL with  $\text{H}_2\text{O}$ . Transfer 2.0 mL dild sample to each of three 16 × 150 mm test tubes. Other dilns may be necessary to obtain 1–3 mg free amino N/L in dild soln.

(b) *Calibration std*.—Transfer 2.0 mL glycine working std soln to each of 3 test tubes.

(c) *Blank*.—Transfer 2.0 mL H<sub>2</sub>O to each of 3 test tubes.

(d) *Reaction*.—Add 1.0 mL ninhydrin color reagent to each test tube. Place tubes in rack, and stopper all tubes with 15–20 mm glass marbles to reduce evapn. Heat exactly 16 min in boiling H<sub>2</sub>O bath, cool 20 min in 20±1° bath, and add 5 mL diln soln. Mix thoroly and det. *A* at 570 nm against H<sub>2</sub>O within 30 min.

(e) *Calculations*.—Average *A* readings for each set of triplicates. Subtract av. blank *A* from *A* of samples and of std.

$$\text{mg Free amino N/L} = \text{net } A \text{ of sample soln} \times 2 \times \text{diln/net } A \text{ of std soln}$$

(f) *Example*.—Av. *A* of blank = 0.050; av. *A* of std = 0.490; av. *A* of wort dild 1 to 100 = 0.380.

$$\text{mg Free amino N/L} = (0.380 - 0.050) \times 2 \times 100 / (0.490 - 0.050) = 150.0$$

Report in whole numbers, i.e., 150 mg free amino N/L.

#### 10.181 Total Reducing Sugars

Prep. sample as in 10.169. If prepd wort contains appreciable amts of suspended matter, remove by centrfg or filtering. Transfer 50 mL sample to 250 mL vol. flask, dil. to vol. at 20°, and mix thoroly. In general, worts do not require clarification for detn of reducing sugars, but if clarification is necessary, proceed as in 10.165. Det. reducing sugars in 10 mL of this soln by Munson-Walker method as in 31.060. Or dil. 50 mL of this soln with H<sub>2</sub>O to 100 mL and use Lane-Eynon method as in 31.059. Express results as % maltose.

### YEAST

#### LIQUID AND PRESSED YEAST

##### Sampling (27)—Procedure

#### 10.182

##### Apparatus

Dry, wide-mouth 1 L containers with suitable cover or dry Mason jars with covers are satisfactory for collecting samples. Jar should hold ca twice vol. of original sample.

#### 10.183

##### Collecting Primary Sample

(a) *Bottom fermenting yeast*.—(1) From small fermenters from which the yeast is collected in cans or tubs, collect at least five 100 mL portions of the yeast slurry at intervals as it is forced out thru bung hole into brink. (2) From large tanks from which the yeast is removed by pump, collect 5–10 100 mL portions of the yeast slurry from sampling cock at regular intervals on discharge side of yeast pump.

(b) *Top fermenting yeast*.—Push aside upper fluffy layer of yeast and take portion from under layer. Collect at least five 100 mL portions from various parts of tank. (For routine work, top fermenting yeast is usually sampled after it has been skimmed into yeast buggy. Mix thoroly before sampling.)

(c) *Any liquid yeast from small tanks or tubs*.—Mix contents of tub thoroly to uniform consistency, taking care to blend in heavier deposits on bottom of vessel and to remove gases. Take ≥500 mL sample from this mixt.

(d) *Pressed yeast*.—Remove portions from different parts of cake—from surface as well as from center—and collect ca 150 g in 1 L beaker. Weigh to nearest 0.1 g. Prep. slurry by adding H<sub>2</sub>O at rate of ca 3 parts H<sub>2</sub>O to 1 part pressed yeast. Again weigh to nearest 0.1 g. With stirring rod, break up yeast portions and stir until liq. suspension is completely uniform.

#### 10.184

##### Preservation of Samples

To prevent changes in analytical results due to autolysis and fermentation, proceed with examination immediately after sampling. Keep sample at 2° or below.

#### 10.185

##### Preparation of Laboratory Sample

Mix primary composite sample thoroly and transfer working amt to sep. container. If lumps or particles of trub are present, pass thru sieve entire bulk sample of liq. yeast, which should amt to ≥500 mL if yeast requires screening, or slurry prepd from ca 150 g pressed yeast. Make sure all lumps and particles are broken up and forced thru sieve. Recover, by scraping, any liq. or solids adhering to sieve, and reincorporate them with sieved sample. Mix well by stirring.

##### Total Solids

(When reporting total solids, state whether alcohol method, 10.188, or 16 hr drying method, 10.191, was used.)

##### Alcohol Method—Official Final Action

#### 10.186

##### Apparatus

(a) *Sieve*.—Approx. 100-mesh.

(b) *Moisture oven*.—See 10.102(b).

(c) *Weighing dish*.—Glass or Al, ≥65 mm id, with cover, and glass stirring rod of such length that it fits within covered dish.

#### 10.187

##### Reagents

(a) *Alcohol*.—Pure alcohol or MeOH, or alcohol denatured with completely volatile liq., such as SDF Nos. 1, 2-B, 3-A, 12-A, 13-A, 23-A.

(b) *Sand*.—Use clean, sharp sand. Wash with H<sub>2</sub>O and dry overnight at 105°. Cool in desiccator. Keep in closed container. Loss of wt of 5 g of this sand when dried 3 hr at 105° must be ≤0.005 g.

#### 10.188

##### Determination

Place ca 5 g dry sand in weighing dish. Weigh dish together with sand, cover, and stirring rod. Transfer to weighing dish ca 10 g well mixed liq. yeast or yeast slurry from pressed yeast, cover, and weigh to nearest mg. Remove cover and add 5 mL alcohol. Mix thoroly with stirring rod. Drop rod into weighing dish. Dry 3 hr (±2 min) at 105°. Cover, cool in desiccator, and weigh.

For liq. yeast, calc. drying loss of aliquot used as % and report total solids to 1 decimal place. For pressed yeast calc. according to following formula:

$$\% \text{ total solids} = D \times S \times 100 / (W \times P),$$

where *P* = wt (g) pressed yeast used for prepg slurry; *S* = total wt (g) yeast slurry; *W* = wt (g) slurry aliquot before drying; and *D* = wt (g) slurry aliquot after drying.

##### 16 Hour Drying Method (28)—Official First Action

#### 10.189

##### Apparatus

(a) *Drying oven*.—Forced-draft or convection type, regulated at 100±2°.

(b) *Moisture dish*.—Diam. 50–65 mm, depth 20 mm, Al, with tight-fitting cover.

(c) *Glass rods*.—3 mm diam. and of such length to fit into covered moisture dish. Fire-polish both ends.

## 10.190

**Standardization of Oven**

Adjust oven to 98–102° after operation  $\geq 30$  min with door closed. Then note and record temp. at 10 min intervals for 2 hr. If temp. at any time is  $< 98^\circ$  or  $> 102^\circ$ , replace thermostat.

Accurately weigh (to 0.1 mg) ca 5 g dried yeast into weighed moisture dish previously dried 1 hr at  $100 \pm 2^\circ$  and cooled in desiccator, **10.192(b)**. Dry in oven 16 hr at  $100 \pm 2^\circ$ , cover, transfer to desiccator, and weigh soon after it reaches room temp. Redry 2 hr, cool, and weigh. If moisture has increased by 0.1%, oven is not operating properly and should be serviced.

## 10.191

**Determination**

Dry moisture dish and stirring rod in oven 1 hr at  $100 \pm 2^\circ$ . Cover, transfer to desiccator, and weigh to 1 mg soon after it reaches room temp. Remove cover, transfer to dish ca 10 g well mixed liq. yeast or yeast slurry from pressed yeast, cover, and reweigh. Spread evenly with stirring rod and place rod in dish. Transfer dish, with cover loose, to oven and dry 16 hr at  $100 \pm 2^\circ$ . Cover, transfer to desiccator, and weigh soon after attaining room temp. Calc. drying loss and report total solids as in **10.188**.

**DRIED YEAST****Total Solids—Official Final Action****Vacuum Oven Method (29)**

## 10.192

**Apparatus**

(a) *Metal dish*.—Diam. ca 55 mm, ht ca 15 mm, provided with inverted slip-in cover fitting tightly on inside. Or, diam. ca 65 mm, ht ca 20 mm, provided with slip-over cover fitting tightly on outside.

(b) *Air-tight desiccator*.— $\text{CaCl}_2$ , reignited  $\text{CaO}$ , and Drierite are satisfactory drying agents.

(c) *Vacuum oven*.—Connected with pump or vac. system capable of maintaining pressure  $\leq 50$  mm Hg, and provided with thermometer passing into oven with bulb near samples. Connect  $\text{H}_2\text{SO}_4$  gas-drying bottle to oven to admit dry air when releasing vac.

## 10.193

**Determination**

Accurately weigh ca 2 g well mixed sample in covered dish, previously dried at 98–100°, cooled in desiccator, and weighed soon after attaining room temp. Loosen cover (do not remove) and heat 5 hr at 98–100° at pressure  $\leq 50$  mm Hg. Admit dry air into oven to bring to atm. pressure. Immediately tighten cover on dish, transfer to desiccator, and weigh soon after it reaches room temp.

**Air Oven Method (30)**

## 10.194

**Determination**

Accurately weigh ca 2 g well mixed sample in covered dish, **10.192(a)**, previously dried at  $100 \pm 1^\circ$ , cooled in desiccator, and weighed soon after it reaches room temp. Loosen cover (do not remove) and heat 16 hr at  $100 \pm 1^\circ$ . Tighten cover, transfer to desiccator, and weigh soon after it reaches room temp.

10.195 **Protein—Official Final Action**

Proceed as in **2.057**, using 0.5 g sample. Digest 30 min after soln clears. % Protein = %N  $\times 6.25$ .

**BREWERS' GRAINS\* (31)  
OFFICIAL FINAL ACTION**10.196 **Sampling**

(a) *Wet brewers' grains*.—Using scoop, collect numerous small samples at uniform intervals during emptying of tub, so that at end of operation composite sample of 25–30 lb (11–14 kg) is obtained in clean, dry bucket. From mash filters, collect numerous small samples in similar manner at equal time intervals from grain conveyor. Mix thoroly and quarter grains carefully so as to obtain representative sample of 3–4 lb (1.4–1.8 kg). Place reduced sample in suitable container with screw- or friction-type cover, add few drops of toluene as preservative, close tightly, and refrigerate.

(b) *Dry brewers' grains*.—See **10.092**. Take great care in sampling dry brewers' grains for analysis, particularly for feed, as it is very difficult to obtain truly representative sample. Because brewers' grains are composed of large husks and small, heavy particles, there is usually difference in composition at different levels of container.

If brewers' grains are in sacks, sample  $\geq 2\%$  of the sacks, using trier as long as ht of sacks. Quarter sample down to ca 250 g (0.5 lb) for laboratory sample.

If brewers' grains are in car, unsacked, it is practically impossible to obtain representative sample because of segregation at bottom of fine heavy material, which is higher in protein than lighter material at top.

Store sample in refrigerator pending laboratory analysis. On each sample container show date of sampling; name of company owning grains at time of sampling; and brew, lot, car, or ref. number or letter for identification. Before making analysis, mix grains thoroly.

10.197 **Preliminary Drying (Wet Brewers' Grains)**

Accurately weigh ( $\pm 0.1$  g) ca 1 kg quartered wet brewers' grains on weighed, shallow, galvanized Fe or Al tray so that layer is  $\leq 6$  mm thick. After spreading, moisten grains with little toluene to inhibit fermentation during drying. Dry in oven at 55–60°, or overnight in air by means of fan and heater, until grains appear air-dry. Note accurately ( $\pm 0.1$  g) wt dried grains and store in moisture-proof container. Thoroly mix dried sample and finely grind 100 g, as in **10.108**. Keep ground portion in moisture-tight container.

10.198 **Moisture**

(a) *On sample after preliminary drying (when available and soluble extracts are determined)*.—Use 5–10 g accurately weighed and ground sample and proceed as in **10.104**. Calc. % moisture in dried grains ( $W$ ). Calc. % moisture,  $M$ , in original wet grains by following formula:

$$M = [(W \times D) + 100(G - D)]/G,$$

where  $G$  = wt wet grains before preliminary drying,  $D$  = wt wet grains after preliminary drying, and  $W$  = % moisture in grains after preliminary drying.

(b) *On sample in wet condition (when only soluble extract is determined)*.—Use ca 15 g sample, accurately weighed into 70 mm Al dish, and dry first at temp.  $< 60^\circ$  until air-dry; then dry addnl 3 hr as in **10.104**.

(c) *On dry brewers' grains*.—Proceed as in (a) and calc. % moisture.

\* For examination of brewers' grains for feeding purposes see Chap. 7.

**Available Extract****10.199 Wet Brewers' Grains**

(a) *Apparatus*.—Mash beakers and counter wts, mashing app., filter paper, funnels, flasks, pycnometers, emptying device, and H<sub>2</sub>O bath. See 10.106.

(b) *Preparation of sample*.—See 10.197. Preparation of finely ground malt.—See 10.108.

(c) *Mashing procedure*.—See 10.136. Proceed as for flaked corn and flaked rice.

(d) *Cooling and filtration*.—See 10.108(c).

(e) *Specific gravity*.—See 10.108(d). Det. corresponding Plato values from 52.009.

(f) *Calculation*.—Use following formulas:

$$\text{Total ext} = P \times (800 + W \text{ in } 60 \text{ g malt} + W \text{ in } 40 \text{ g dried grains}) / (100 - P),$$

where  $P$  = g ext in 100 g wort (Plato), and  $W$  = moisture (g).

$$\% \text{ Available ext in wet grains, dry basis} = [(E \text{ in mixt.} - E \text{ in } 60 \text{ g malt}) \times 10,000] / 40(100 - M \text{ of dried grains}),$$

where  $E$  = g ext, and  $M$  = % moisture.

$$\% \text{ Available ext in wet grains, as-is basis}$$

$$= (\text{available } E, \text{ dry basis}) \times (100 - M \text{ of wet grains}) / 100,$$

where  $E$  = % ext, and  $M$  = % moisture.

**10.200 Dry Brewers' Grains**

*Preparation of sample*.—Grind finely 100 g sample and proceed as in 10.199. Calc. ext as in 10.137.

**Soluble Extract (Wet Brewers' Grains)****10.201 On Sample After Preliminary Drying**

(a) *Mashing procedure*.—"Mash in"  $25 \pm 0.05$  g unground sample with 350 mL H<sub>2</sub>O at 70° in mash beaker. Place mash beakers in mashing app., 10.106(c) and (d), contg H<sub>2</sub>O previously heated to 70–71°, and set stirrers in motion. Hold mash 60 min at mash temp. of  $70 \pm 0.5^\circ$ .

(b) *Cooling and filtering*.—See 10.108(c). Dil. mash to 425 g.

(c) *Specific gravity*.—See 10.108(d). Det. corresponding Plato values from 52.009.

(d) *Calculation*.—Use following formulas:

$$\% \text{ Sol. ext in wet grain, dry basis} = P(M \text{ of dried grains} + 1600) \times 100 / (100 - P)(100 - M \text{ of dried grains}).$$

$$\% \text{ Sol. ext in wet grains, as-is basis}$$

$$= (E, \text{ dry basis})(100 - M \text{ of wet grains}) / 100,$$

where  $P$  = g ext in 100 g wort (Plato, 52.009),  $E$  = % ext, and  $M$  = % moisture.

**10.202 On Sample in Wet Condition**

*Mashing method*.—Using  $100 \pm 0.05$  g well mixed and quar-

tered brewers' grains and 300 mL H<sub>2</sub>O at 71°, proceed as in 10.201. Dil. mash to 450 g.

*Calculation*.—Use following formulas:

$$\% \text{ Sol. ext, as-is basis} = P(M + 350) / (100 - P);$$

$$\% \text{ Sol. ext, dry basis} = E \times 100 / (100 - M);$$

where  $P$  = g ext in 100 g wort (Plato, 52.009),  $M$  = % moisture content, and  $E$  = % sol. ext, as-is.

Report sol. ext on as-is and dry basis in %, to 1 decimal place.

**10.203 Soluble Extract (Dry Brewers' Grains)**

Proceed as in 10.201, but use following formulas:

$$\% \text{ Sol. ext, as-is basis} = P(1600 + M) / (100 - P);$$

$$\% \text{ Sol. ext, dry basis} = E \times 100 / (100 - M);$$

where  $P$  = g ext in 100 g wort (Plato, 52.009),  $E$  = % sol. ext, as-is, and  $M$  = % H<sub>2</sub>O in dry brewers' grains.

# 11. Beverages: Wines

## 11.001 Physical Examination—Procedure

Note and record following: (a) Whether container is "bottle full"; (b) appearance, whether bright or turbid and presence of sediment; (c) condition when opened, whether still, gaseous, or carbonated; (d) color and depth of color; (e) odor, whether vinous, foreign, or acetous; and (f) taste, whether dry, sweet, vinous, foreign, or acetous.

Immediately det. sp gr and those ingredients that are subject to change, such as alcohol, sugars, and acids.

## 11.002 Specific Gravity—Official Final Action

Det. sp gr at 20/20° by pycnometer as in 9.011, or by small, accurately graduated hydrometer.

### Color in White Wines (7) Official Final Action

#### 11.003

#### Apparatus and Reagents

(a) *White wine colorimeter*.—Double beam filter photometer utilizing W incandescent lamp with Corning 5-61 high pass filter, Se photocells, 1" path test and ref. cells, and zero set cell for calibration. Combination of responses of photocell and filter approximates monochromatic peak at 430 nm. Available from Huggins Engineering Co., 2070 Walsh Ave, Santa Clara, CA 95050.

(b) *Potassium chromate std soln*.—0.0002059M. Dissolve 0.0400 g  $K_2CrO_4$  primary std (J. T. Baker Chemical Co., No. 3058) in 0.05N KOH and dil. to 1 L with 0.05N KOH.

#### 11.004

#### Determination

Let instrument warm up 2 hr. Stdze with  $K_2CrO_4$  soln according to manufacturer's instructions. %T should be reproducible to  $\pm 0.1\%$ .

Fill ref. and test cells with  $H_2O$ , and place both in colorimeter. Set indicator knob to zero, and null colorimeter by adjusting zero set knob. Remove test cell and replace with zero set cell. Null meter by adjusting indicator. Indicator should read ca 98.5 on duplicate tests. Repeat each hr or after every 10–15 samples.

With zero set cell in place, set indicator to value (ca 98.5) detd above. Null meter with zero set knob. Replace zero set cell with test cell contg wine sample. Null meter by adjusting indicator. Read %T on indicator.

### Alcohol

## 11.005 By Volume from Specific Gravity Official Final Action

Measure 100 mL sample into 300–500 mL distn flask, noting temp., and add 50 mL  $H_2O$ . Attach flask to vertical condenser by means of bent tube, distil almost 100 mL, and dil. to 100 mL at same temp. (Foaming, which sometimes occurs, especially with young wines, may be prevented by adding small amt of antifoam material.) For wines that contain abnormal amt of HOAc, neutze exactly with 1N NaOH soln (calcd from acidity, 11.037) before proceeding with distn (unnecessary for wines of normal taste and odor). Proceed as in 9.011, at room temp. if desired, and obtain corresponding % alcohol by vol. from 52.003.

## 11.006 By Volume from Refraction (Rapid Method) Official Final Action

Det. immersion refractometer reading of distillate obtained in 11.005 and find corresponding % alcohol from 52.004.

## 11.007 By Weight—Official Final Action

From 52.005, obtain % alcohol by wt in distillate corresponding to % alcohol by vol., multiply by sp gr of distillate, and divide by sp gr of sample.

### By Dichromate Oxidation (2) Official Final Action

#### 11.008

#### Principle

Sample is steam distd into acidified  $K_2Cr_2O_7$  soln of known vol. and concn. Oxidn of EtOH to HOAc is completed by heating. Unreacted dichromate is detd by titrn with std  $Fe(NH_4)_2(SO_4)_2$  soln, using o-phenanthroline as indicator.

#### 11.009

#### Apparatus

*Micro Kjeldahl apparatus*.—With gas micro-burner. See Fig. 11.01. (Glassware available from Scott Laboratories, Inc., PO Box 3576, San Rafael, CA 94901.)

#### 11.010

#### Reagents

(a) *Potassium dichromate soln*.—Add 325 mL  $H_2SO_4$  to ca 400 mL  $H_2O$  in 1 L vol. flask. Mix and cool to 80–90°. Add 33.768 g  $K_2Cr_2O_7$  (primary std). Dissolve, cool, and dil. to vol. with  $H_2O$  at 20°.

(b) *Ferrous ammonium sulfate soln*.—Dissolve 135.5 g  $FeSO_4(NH_4)_2SO_4 \cdot 6H_2O$  in ca 500 mL  $H_2O$  in 1 L vol. flask. Add 30 mL  $H_2SO_4$ . Dil. to vol. with  $H_2O$  at 20°.

(c) *1,10-Phenanthroline ferrous sulfate indicator*.—Dissolve 0.695 g  $FeSO_4 \cdot 7H_2O$  in ca 50 mL  $H_2O$ , add 1.485 g o-phenanthroline.  $H_2O$ , and dil. to 100 mL with  $H_2O$ . (Prepd soln available from G. Frederick Smith Chemical Co.)

#### 11.011

#### Determination

See Fig. 11.01. To begin distn, boil  $H_2O$  in steam generator. Open steam trap discharge. Turn 3-way stopcock so that steam from trap vents thru side tube and distg bulb is closed. Place 25 mL  $K_2Cr_2O_7$  soln in 50 mL erlenmeyer under condenser with tip below surface of soln. Close sample stopcock and place small amt  $H_2O$  in sample funnel. Distg bulb is empty and micro-burner is not lighted.

Transfer 1 mL samples as follows: Fill 1 mL pipet (class A) slightly over mark, and wipe excess wine from exterior. Hold pipet vertical; with tip touching inside neck of sample bottle, drain to mark. Drain pipet completely into sample funnel. Open sample stopcock to drain sample into still; then reclose. Add small amt  $H_2O$  to funnel, drain into still, and rinse with  $H_2O$  until distg bulb is half filled. Place  $H_2O$  in funnel to ensure seal.

Close steam trap discharge with pinch clamp. Open 3-way stopcock, permitting steam to enter bulb while vent is closed. Light micro-burner. Distil until receiving flask contains ca 40 mL, lower flask, and rinse outside of condenser outlet into flask with  $H_2O$ . Stopper flask and immerse to shoulder in  $60 \pm 2^\circ H_2O$ .

Admit cold  $H_2O$  into steam generator to flush contents of distg bulb into steam trap. Refill bulb with  $H_2O$ , flush again, open trap

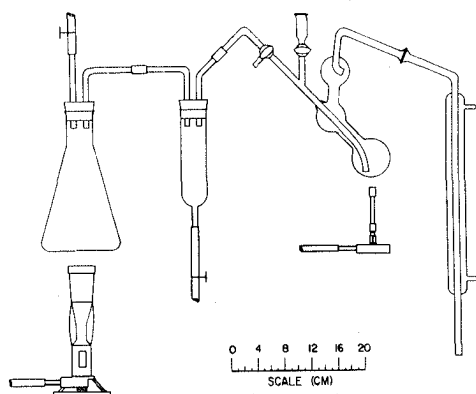

FIG. 11.01—Distillation apparatus for chemical determination of alcohol in wine

discharge, and vent 3-way stopcock. App. is now ready for next sample.

Remove flask from bath after 20–25 min. Rinse contents into 500 mL flask with H<sub>2</sub>O. Titr. with FeSO<sub>4</sub>(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> soln to almost clear green in front of daylight fluorescent light, add 3 drops indicator, and titr. to end point (change is from blue-green to brown) (*V* mL).

Since FeSO<sub>4</sub>(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> soln is slowly oxidized by air, perform blank detn daily by titrg 25 mL K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> (*V'* mL). Discard FeSO<sub>4</sub>(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> soln that has been standing in buret >30 min.

Calc. % alcohol by vol. =  $25.00 - (25 \times V/V')$ .

#### 11.012 ★ Glycerol in Dry Wines ★ Official Final Action

Glycerol is isolated from other org. material and detd by oxdn with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> or by direct weighing. See 11.010, 12th ed.

#### 11.013 ★ Glycerol in Sweet Wines ★ Official Final Action

Glycerol is isolated from other org. material and detd by oxdn with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> or by direct weighing. See 11.011, 12th ed.

#### 11.014 Extract—Official Final Action

(a) *By specific gravity of dealcoholized wine.*—Calc. sp gr of dealcoholized wine,  $D = S + 1 - S'$ , where *S* = sp gr of sample, 11.002, and *S'* = sp gr of alc. distillate, 11.005.

From 52.008, det. % by wt of ext in dealcoholized wine corresponding to value of *D*. This figure × value of *D* = g ext/100 mL wine.

(b) *By evaporation.*—(1) *In dry wines, extract content less than 3 g/100 mL.*—In 75 mL flat-bottom Pt dish, ca 85 mm diam., evap. 50 mL sample on H<sub>2</sub>O bath to sirupy consistency. Heat residue 2–5 hr in drying oven at 100°, cool in desiccator, and weigh as soon as room temp. is reached.

(2) *In sweet wines.*—If ext content is 3–6 g/100 mL, treat 25 mL sample as in (1). If ext is >6 g/100 mL, accept result obtained as in (a), and attempt no gravimetric detn because of inaccurate results obtained by drying fructose at high temp.

#### 11.015 Nonsugar Solids (Sugar-Free Extract)—Official Final Action

Subtract amt of reducing sugars before inversion, 11.016, plus sucrose, if present, from ext, 11.014.

★ Surplus method—see inside front cover.

#### 11.016 Reducing Sugars—Official Final Action

(a) *Dry wines.*—Place 200 mL sample in porcelain dish, exactly neutze with 1*N* NaOH, calcg amt required from acidity, 11.037, and evap. to ca 50 mL. Transfer to 200 mL vol. flask, add enough neut. Pb(OAc)<sub>2</sub> soln, 31.021(d), to clarify, dil. to vol. with H<sub>2</sub>O, shake, and filter thru folded paper. Remove Pb with dry K oxalate and det. reducing sugars as in 31.038.

(b) *Sweet wines.*—Approximate sugar content by subtracting 2 from ext, 11.014, and use such amt of sample that aliquot taken for Cu reduction contains ≤240 mg invert sugar. Proceed as in (a).

#### 11.017 Sucrose—Official Final Action

(a) *By reducing sugars before and after inversion.*—Proceed as in 9.112(b).

(b) ★ *By polarization.* ★—See 11.015(b), 12th ed.

#### 11.018 ★ Commercial Glucose—Procedure ★

By polarization. See 11.016, 12th ed.

#### 11.019 Ash—Official Final Action

Proceed as in 31.012 or 31.013, using residue from 50 mL sample. Char carefully (decrepitation), and ash at ≤550°.

#### 11.020 Alkalinity of Ash—Official Final Action

Evap. 10 mL sample to dryness in Pt dish and ash at 550°. If solid content of sample is high, it may be necessary to moisten ext with ether and to burn off carefully over flame to prevent spattering. If any C remains, add few mL H<sub>2</sub>O, dry, and again heat to 550°. To ash add 10 mL 0.1*N* H<sub>2</sub>SO<sub>4</sub>, bring acid in contact with all of the ash, and fill dish ca ¾ full of boiling H<sub>2</sub>O. Cool, add 4 drops *Me purple* (available from Fisher Scientific Co., Cat. No. SO-I-9) or *Me orange*, and immediately titr. excess acid with 0.1*N* NaOH. Express alky as mL 0.1*N* H<sub>2</sub>SO<sub>4</sub> required to neutze ash from 100 mL sample.

#### 11.021 Copper—Official Final Action

See 9.029–9.035.

#### Iron—Official Final Action

#### 11.022 Atomic Absorption Method

Pipet 20 mL 40° proof wine into 200 mL vol. flask, add 88 mL 95% alcohol from graduate, and mix well. Dil. almost to vol. with H<sub>2</sub>O and mix well. Let soln reach room temp., dil. to 200 mL with H<sub>2</sub>O, and mix well. Proceed as in 9.038. Multiply results by 10 to obtain ppm Fe in original wine sample.

#### 11.023 TPTZ Colorimetric Method

Prep. sample as in 11.022, and proceed as in 9.042.

#### Potassium (3)—Official Final Action

#### 11.024

#### Reagents and Apparatus

(a) *Potassium std solns.*—Dry reagent grade KCl at 100° overnight and dil. 1.9068 g to 1 L with H<sub>2</sub>O. Dil. 10 mL of this soln to 100 mL and further dil. 1, 2, 4, 6, 8, and 10 mL of dild soln to 100 mL to make std solns contg, resp., 1, 2, 4, 6, 8, and 10 ppm K in H<sub>2</sub>O. Store std solns in clean, dry polyethylene bottles.

(b) *Flame spectrophotometer.*—Beckman Model DU with oxy-hydrogen flame and photomultiplier accessory, or equiv. instrument.

## 11.025

**Determination**

Dil. 10 mL sample 50–200 times with H<sub>2</sub>O if necessary to fall within %T range of stds. Set instrument, fill sample cup, and burn. Read %T 3–5 times at 740 nm ( $T_b$ ), 768 nm ( $T_{max.}$ ), and 790 nm ( $T_a$ ). ( $T_{max.} = T$  at max. emission,  $T_b = T$  before max.,  $T_a = T$  after max.) Det. %T for 1–10 ppm K std solns immediately after sample under same conditions, and plot "unit rise" against ppm K to obtain "semipermanent" calibration curve:

For stds:  $T_{max.} - [(T_a + T_b)/2] = \text{"Unit Rise X"}$

For sample:  $T_{max.} - [(T_a + T_b)/2] = \text{"Unit Rise Y"}$

Jet correction: Check "semipermanent" calibration curve frequently with stds. Calc. % deviation, if any, and apply correction to sample, as:

Theoretical Unit Rise from Calibration Curve/Unit Rise X = corr. factor. Then, Unit Rise Y  $\times$  corr. factor = corrected Unit Rise Y.

ppm K in sample = Diln factor  $\times$  ppm equiv. to Unit Rise Y taken from calibration curve.

**Sodium (3)—Official Final Action**

## 11.026

**Reagents and Apparatus**

Prep. std solns as in 11.024(a), except use 2.5421 g reagent grade NaCl. Use flame spectrophtr, 11.024(b).

## 11.027

**Determination**

Proceed as in 11.025, except dil. sample 50–100 times as necessary to fall within %T range of stds. For Na, ( $T_b$ ) = 570, ( $T_{max.}$ ) = 589, and ( $T_a$ ) = 610. Calc. ppm Na in sample as in 11.025.

**11.028 Chlorides—Official Final Action****Method I**

To 100 mL dry wine or 50 mL sweet wine add enough Na<sub>2</sub>CO<sub>3</sub> to make distinctly alk. Evap. to dryness, ignite at  $\leq 500^\circ$ , cool, ext residue with hot H<sub>2</sub>O, acidify H<sub>2</sub>O ext with HNO<sub>3</sub> (1+4), and det. Cl as in 3.072 or 3.074.

**Method II (4)**

## 11.029

**Apparatus**

(a) *pH meter*.—With millivolt scale, Beckman Zeromatic, or equiv.

(b) *Electrodes*.—Beckman Instruments general purpose glass electrode No. 41263 as ref. electrode and Beckman No. 19151 Ag-AgCl pressed billet electrode with 30" lead and pin connector as indicating electrode. Other electrode combinations such as Beckman No. 39187 Ag billet combination electrode may be used.

(c) *Magnetic stirrer*.—With glass or plastic coated stirring bar.

(d) *Buret*.—10 mL with 0.05 mL subdivisions.

## 11.030

**Reagents**

(a) *Potassium chloride*.—Reagent grade contg  $\leq 0.005\%$  Br. Dry in desiccator several days before use.

(b) *Distilled water*.—Cl-free. Use wherever H<sub>2</sub>O is specified.

(c) *Chloride std soln*.—1 mg Cl/mL. Weigh 2.1028 g KCl, transfer to 1 L vol. flask, and dil. to vol. with H<sub>2</sub>O.

(d) *Silver nitrate std soln*.—1 mL = 1 mg Cl. Weigh 4.7914 g reagent grade AgNO<sub>3</sub>, transfer to 1 L vol. flask, and dil. to vol. with H<sub>2</sub>O.

## 11.031

**Determination**

Connect glass electrode to input terminal and indicating

electrode to ref. terminal of pH meter set to read on  $\pm 700$  millivolt (mv) scale. Warm up  $\geq 30$  min. Pipet 5.0 mL std Cl soln into 250 mL beaker. Adjust vol. to ca 100 mL with H<sub>2</sub>O and add 1.0 mL HNO<sub>3</sub> by pipet. Insert electrodes so that billet is completely covered, add stirring bar, and titr. with std AgNO<sub>3</sub> soln, stirring moderately. Add in 1.00 mL increments until 4.0 mL have been added, then 0.20 mL increments until 2.0 mL more have been added, then 1.00 mL increments to total of 10.00 mL. Read buret to 0.01 mL and mv scale to 1 mv after addn of each increment. Record readings. Let pH meter stabilize  $\geq 30$  sec before each reading. Plot observed mv against mL soln added and det. equivalence point (inflection) voltage from resulting curve. This value will vary with electrode system used.

Use of glass electrode as ref. electrode is reverse of usual function; hence curve obtained will be reverse of those produced by other electrode combinations. Rinse electrodes before each use.

Pipet 5.0 mL std Cl soln into 250 mL beaker, and add 95 mL H<sub>2</sub>O and 1.0 mL HNO<sub>3</sub>. Insert electrodes, stir, and titr. with std AgNO<sub>3</sub> soln to predetd equivalence voltage, adding titrant dropwise as end point is reached. Repeat until results are in close agreement. Conduct all titrations within  $5^\circ$  of temp. of equivalence point detn. Repeat this detn at least daily or before each group of samples.

Pipet 50 mL wine into 250 mL beaker, add 50 mL H<sub>2</sub>O and 1.0 mL HNO<sub>3</sub>, and titr. as above.

$$\text{ppm Cl} = (V_w/V_s) \times C \times 2 \times 10,$$

where  $V_w$  = mL std AgNO<sub>3</sub> used by sample,  $V_s$  = mL std AgNO<sub>3</sub> used by std Cl soln, and  $C$  = 5.0 = mg Cl in 5 mL std Cl soln used.

**Phosphorus (5)—Official Final Action**

(Caution: See 51.018, 51.019, 51.026, and 51.028.)

## 11.032

**Reagents**

(a) *Molybdovanadate reagent*.—Prep. as in 2.022(a), except use 200 mL 70% HClO<sub>4</sub>.

(b) *Phosphate std soln*.—1 mg P<sub>2</sub>O<sub>5</sub>/mL. Dissolve 1.9174 g pure, dry (2 hr at 105°) KH<sub>2</sub>PO<sub>4</sub> in 1 L H<sub>2</sub>O. Prep. fresh weekly.

## 11.033

**Preparation of Standard Curve**

Prep. series of std solns contg 0.0, 0.1, 0.2, 0.3, and 0.4 mg P<sub>2</sub>O<sub>5</sub>/mL. Perform following operations within 5 min: Pipet 5 mL aliquots into 100 mL vol. flasks, and add 50 mL H<sub>2</sub>O and 4 mL 70% HClO<sub>4</sub>. Pipet 20 mL molybdovanadate reagent into each flask, dil. to vol. with H<sub>2</sub>O, and shake thoroly. Let stand 15 min.

Det. A of blank and stds in set of matched cells against H<sub>2</sub>O as ref. at 400 nm. Correct stds for A of blank and plot corrected A against concn in mg P<sub>2</sub>O<sub>5</sub>/100 mL soln.

## 11.034

**Determination**

(a) *Wet ash method*.—Pipet 5 mL sample into 100 mL Pyrex beaker and evap. to dryness on steam bath. Add 15 mL HNO<sub>3</sub> and few SiC boiling chips, cover with watch glass, and heat gently until residue dissolves. Boil gently 10–15 min to oxidize easily oxidizable org. matter, cool, add 4 mL 70% HClO<sub>4</sub>, and boil gently until soln fumes copiously and is nearly colorless. (Remove watch glass when soln starts to fume. Do not evap. to dryness.) If soln is brown, add 2 mL HNO<sub>3</sub> and boil again. Cool slightly, add ca 25 mL H<sub>2</sub>O, boil few min, and transfer to 100 mL vol. flask. Rinse beaker with H<sub>2</sub>O, adding washings to flask to total vol. of 50–60 mL.

Within 5 min for series, add 20 mL molybdovanadate reagent to each flask, dil. to 100 mL, mix thoroly, and read A at 400 nm

after 15 min. Carry blank and std thru entire detn. Subtract  $A$  of blank from that of sample.

(b) *Dry ash method*.—Pipet 5 mL sample into Pt dish and evap. to dryness on steam bath. Carefully char over low flame and ash in furnace at  $\leq 550^\circ$ . Pipet in 4 mL 70%  $\text{HClO}_4$ , add ca 20 mL  $\text{H}_2\text{O}$ , and warm to dissolve ash. Transfer quant. to 100 mL vol. flask, cool to room temp., and proceed as in (a).

$$\text{mg P}_2\text{O}_5/100 \text{ mL} = A_{\text{sample}} \times 20/A_1 \text{ mg std.}$$

### 11.035 Sulfates—Official Final Action

See 30.083.

### 11.036 pH—Official Final Action

Let pH meter with glass and calomel electrodes warm up before use according to manufacturer's instructions. Check meter with freshly prepd, satd, aq. soln of K bitartrate, 50.007(b). Adjust meter to read 3.55 at  $20^\circ$ , 3.56 at  $25^\circ$ , or 3.55 at  $30^\circ$ .

Rinse electrodes free of bitartrate by dipping in  $\text{H}_2\text{O}$  and then in sample. Place electrodes in fresh sample, det. temp., and read pH to nearest 0.01 unit.

### 11.037 Total Acidity—Official Final Action

#### *American Society of Enologists Method (6)*

Remove  $\text{CO}_2$ , if present, by either of following methods: (1) Place ca 25 mL sample in small erlenmeyer and connect to  $\text{H}_2\text{O}$  aspirator. Agitate 1 min under vac. (2) Place ca 25 mL sample in small erlenmeyer, heat to incipient boiling and hold 30 sec, swirl, and cool.

Add 1 mL phthln indicator soln to 200 mL hot, boiled  $\text{H}_2\text{O}$  in 500 mL wide-mouth erlenmeyer. Neutze to distinct pink. Add 5.00 mL degassed sample and titr. with 0.1N (or 0.0667N) stdzd NaOH to same end point, using well-illuminated white background.

Calc. g tartaric acid/100 mL wine =  $\text{mL NaOH} \times \text{normality} \times 0.075 \times 100/5$ . If 0.0667N alkali is used, g tartaric acid/100 mL =  $\text{mL NaOH}/10$ .

### Total Volatile Acidity (7)—Official Final Action

#### 11.038

#### *Apparatus*

(a) *Steam distillation apparatus*.—See Fig. 9:03.

(b) *Cash electric still*.—See Fig. 11:02. Consists of outer chamber, inner chamber, trap, 2-way stopcock, elec. coil heater, and glass "T" inlet-outlet for  $\text{H}_2\text{O}$ . All parts are of Pyrex. Residue in inner chamber after distn is flushed out automatically by vac. action when current is shut off. Addn of  $\text{H}_2\text{O}$  thru funnel above stopcock gives automatic spray bath to inner chamber, and waste drains thru outlet in glass "T." Two-way stopcock permits introduction of sample, serves as escape vent for  $\text{CO}_2$ , and allows introduction of wash  $\text{H}_2\text{O}$ . (Available from VWR Scientific, Inc., PO Box 3200, San Francisco, CA 94119, Cat. No. 26308 001.)

#### 11.039

#### *Preparation of Sample*

Remove dissolved  $\text{CO}_2$  from ca 50 mL sample by either: Placing under low vac. ( $\text{H}_2\text{O}$  aspirator) 2 min with continuous stirring; or bringing to incipient boiling under air condenser and cooling immediately.

#### 11.040

#### *Determination*

(a) *Steam distillation apparatus*.—Add ca 600 mL boiled  $\text{H}_2\text{O}$  to outer chamber of still. Pipet 25 mL freshly prepd sample into inner chamber and stopper. Boil  $\text{H}_2\text{O}$  3 min with sidearm open. Close and distil ca 300 mL into erlenmeyer. Add 0.5 mL phthln

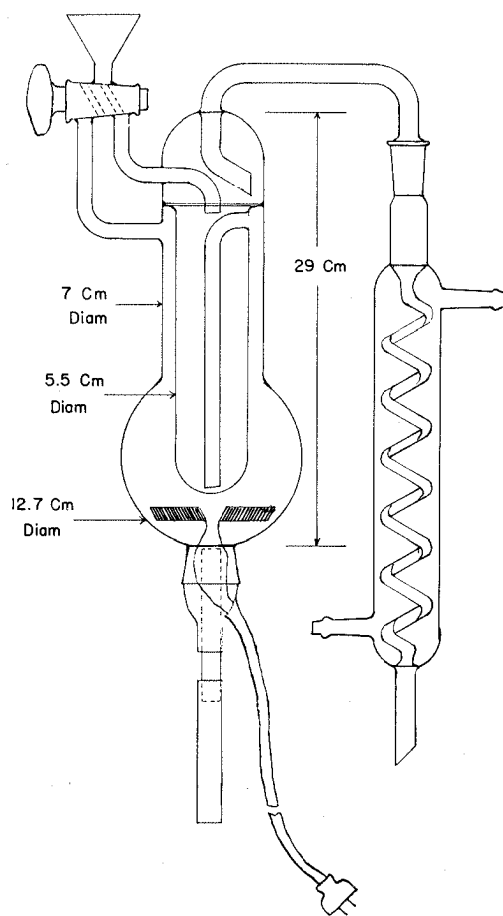

FIG. 11:02—Volatilic acid still (Cash still)

to distillate and titr. rapidly with 0.1N NaOH until pink persists 15 sec. Express results as g HOAc/100 mL =  $\text{mL 0.1N NaOH} \times 0.006 \times 4$ .

(b) *Cash electric still*.—Add  $\text{H}_2\text{O}$  and pipet sample as in (a). Rinse funnel with ca 5 mL  $\text{H}_2\text{O}$ . Distil ca 300 mL into erlenmeyer. Titr. and express results as in (a). (Disconnect heating coil immediately and empty still by opening drain tube and stopcock to inner tube. Rinse still with two 10–15 mL portions  $\text{H}_2\text{O}$  by adding thru funnel; evacuate each portion thru drain tube.)

### Volatilic Acidity—Exclusive of $\text{SO}_2$

#### 11.041 By Barium Hydroxide Treatment (8) Official First Action

Pipet 50 mL sample into 100 mL vol. flask. If white, add 2–3 drops phthln, and neutze to decided pink with clear satd  $\text{Ba}(\text{OH})_2$  soln; if red, add enough  $\text{Ba}(\text{OH})_2$  soln to bring mixt. to ca pH 8, using phthln as external indicator. Let mixt. stand 30 min and keep at phthln end point by adding more  $\text{Ba}(\text{OH})_2$  if necessary. Dil. to 100 mL, mix, and filter rapidly thru fluted, rapid paper (such as Whatman No. 2). Pipet 50 mL prepd sample and 1 mL  $\text{H}_2\text{SO}_4$  (1+3) into inner chamber of still, 11.038(a) or (b), and stopper. Proceed as in 11.040. Express results as g HOAc/100 mL as in 11.040(a).

#### By Mercuric Oxide Treatment (9)—Official Final Action

#### 11.042

#### *Apparatus and Reagents*

(a) *Cash electric still*.—See 11.038(b) and Fig. 11:02.

(b) *Antifoam soln.*—Dil. 1 mL Antifoam C Emulsion to 50 mL with H<sub>2</sub>O.

(c) *Mercuric oxide soln.*—Dissolve 1 g red HgO in 100 mL H<sub>2</sub>SO<sub>4</sub> (1+9).

(d) *Phenolphthalein indicator soln.*—Dissolve 1 g phthln in 70 mL alcohol, add 30 mL H<sub>2</sub>O, and mix.

(e) *Sodium hydroxide std soln.*—0.0167*N*. Prep. as in 50.032–50.034. Stdze as in 50.035 or 50.036, using phthln indicator, (d).

**11.043****Determination**

(Caution: See 51.065.)

Pipet 10 mL sample into funnel of still, (a), letting it flow into inner tube. When analyzing young wines, add 2–3 drops anti-foam soln, (b), to funnel. Rinse sample and antifoam soln into inner tube with ca 5 mL H<sub>2</sub>O. Add 2 mL HgO soln, (c), to funnel (to form nonvolatile mercuric bisulfite complex with SO<sub>2</sub>), and rinse into inner tube with ca 5 mL H<sub>2</sub>O. Turn stopcock so that outer chamber of still is open to atm., and heat ca 600 mL H<sub>2</sub>O in outer chamber until steam escapes. After 15 sec, close stopcock and collect 100 mL distillate in 250 mL erlenmeyer. Disconnect heating coil immediately and empty still by opening drain tube to outer chamber and stopcock to inner tube. Rinse inner tube with two 10–15 mL portions H<sub>2</sub>O by adding thru funnel; evacuate each portion thru drain tube. Bring distillate to bp on hot plate and boil ≤30 sec. Add 3 drops phthln indicator soln, (d), and titr. while still hot with NaOH std soln, (e), to pink end point that lasts 15–30 sec.

$$\text{g HOAc}/100 \text{ mL} = \text{mL NaOH} \times N \times 0.60,$$

where *N* = normality of NaOH soln.

**11.044 Fixed Acidity—Official Final Action**

Calc. fixed acidity by multiplying total volatile acidity by 1.25 for tartaric, 1.12 for malic, or 1.17 for citric acid (hydrate), and subtracting product from total acidity.

**Total Tartaric Acid (10)—Official Final Action****11.045 Titration Method**

Neutze 100 mL sample with 1*N* NaOH, calcd from acidity, 11.037, mL 1*N* alkali necessary. If >10 mL alkali is added, evap. to ca 100 mL. Add, to neutzd soln, 0.075 g tartaric acid for each mL 1*N* alkali added. It is essential that the tartaric acid be pure; recrystallize from H<sub>2</sub>O, if necessary. After tartaric acid dissolves, add 2 mL HOAc and 15 g KCl. After KCl dissolves, add 15 mL alcohol, stir vigorously until KHC<sub>4</sub>H<sub>4</sub>O<sub>6</sub> begins to ppt, and refrigerate ≥15 hr at 15–18°.

Decant onto gooch prepd with very thin film of asbestos, or onto filter paper in buchner. Wash ppt from beaker with filtrate (keep cold) and finally rinse beaker and filter 3 times with few mL mixt. of 15 g KCl, 20 mL alcohol, and 100 mL H<sub>2</sub>O, using ≤20 mL wash soln in all. Transfer asbestos or paper and ppt to beaker in which pptn was made; wash gooch or buchner with hot H<sub>2</sub>O, using ca 50 mL in all; heat to bp, and titr. hot soln with 0.1*N* NaOH, using phthln. Increase number of mL 0.1*N* alkali required by 1.5 mL to allow for solubility of ppt. Under these conditions 1 mL 0.1*N* alkali = 0.015 g tartaric acid. To obtain g total tartaric acid/100 mL wine, subtract wt tartaric acid added from this result.

**11.046 ★ Bitartrate Method ★**

See 22.063★.

★ Surplus method—see inside front cover.

**11.047 ★ Citric and Malic Acids—Official First Action ★**

For citric and malic acids occurring in normal wines in small amts only, use 100 mL sample and evap. to 45 mL. After saponification, 22.063★, proceed as in 22.064★, 22.067★, or 22.075.

**11.048 Lactic Acid (11)—Official Final Action**

Transfer 25 mL sample to 250 mL vol. flask, add ca 25 mL H<sub>2</sub>O and 100 mL alcohol, and shake vigorously. Dil. to vol. with alcohol and filter thru folded paper. Transfer 200 mL filtrate to 400 mL beaker and evap. to ca 25 mL. Add 50 mL H<sub>2</sub>O and again evap. to 25 mL. Transfer material to continuous extractor with 25 mL H<sub>2</sub>O and proceed as in 16.030–16.031.

**11.049 Tannin—Official Final Action**

See 9.100.

**11.050 Total Nitrogen—Official Final Action**

Det. N in 50 mL sample as in 2.057. Crude protein = *N* × 6.25.

**11.051 ★ Pentosans—Official Final Action ★**

(Applicable to dry wines only)

See 11.044, 10th ed.

**Free Aldehydes (12)—Official Final Action****Direct Method****11.052****Reagents**

See 9.060.

**11.053****Determination**

Pipet 50 mL sample, contg ≤30 mg acetaldehyde, into 500 mL distg flask and proceed as in 9.063, beginning "... add 50 mL satd borax soln, ..."

**Caramel—Official Final Action****Mathers Test (13)****11.054****Reagents**

(a) *Pectin soln.*—Dissolve 1 g pectin in 75 mL H<sub>2</sub>O, add 25 mL alcohol to preserve, and shake well before using.

(b) *2,4-DNPH soln.*—Dissolve 1 g 2,4-dinitrophenylhydrazine in 7.5 mL H<sub>2</sub>SO<sub>4</sub> and dil. to 75 mL with alcohol. (If kept in g-s bottle, soln will remain clear and stable several months.)

**11.055****Preliminary Test**

Place 10 mL filtered sample in Babcock cream bottle, 16.157(a), or other centrf. tube. Add 1 mL pectin soln and mix; add 3–5 drops HCl and mix; fill bottle with alcohol (ca 50 mL), mix, centrf., and decant. Dissolve ppt in 10 mL H<sub>2</sub>O, and add HCl and alcohol as above; shake well, centrf., and decant. Repeat operation until alc. liq. is colorless. Finally, dissolve gelatinous residue in 10 mL hot H<sub>2</sub>O. If soln is colorless, caramel is absent; if soln is clear brown, caramel may be present. Confirm as follows: Add 1 mL 2,4-DNPH soln, mix, and heat 30 min in boiling H<sub>2</sub>O. Ppt forms if caramel is present.

**11.056****★ Confirmatory Test ★**

See 11.047, 10th ed.

**Cyanide (14)—Official First Action****11.057****Wines, Other Nondistilled Products,  
and Products Containing Sulfur Dioxide**

(a) *Control test*.—Add 27 mL  $K_4Fe(CN)_6 \cdot 3H_2O$  working soln (equiv. to 10  $\mu g$  CN), 9.102(a)(2), to 100 mL  $H_2O$  in 500 mL 3-neck flask which has thermometer in screw-cap adaptor in one side neck and gas inlet tube connected to N (or  $CO_2$ ) in other. Pack lower tube of flange assembly (E), which fits into top of condenser, with 10 cm column of  $PbO_2$  (ca 7 g), which is held in position by cotton wool plugs at each end. Connect center neck of flask to condenser, place ground-glass flange assembly in top of condenser, and connect hooks with springs. Insert test paper as in 9.103(a). Remove thermometer momentarily, add 10 mL  $H_2SO_4$  (1+9) and 10 mg *powd*  $Cu_2Cl_2$ , and immediately replace thermometer. Proceed as in 9.103(a), except maintain contents of flask at  $90^\circ$  for duration of test and heat 30 min. (It may be necessary to turn on N before  $90^\circ$  is reached to avoid "blow back.")

(b) *Samples*.—Use 100 mL sample (or other suitable aliquot) and evaluate results as for distd spirits, 9.103. Similarly, analyze blank of 100 mL  $H_2O$ .

**Carbon Dioxide—Official First Action****Manometric Method (15)****11.058****Reagents**

(a) *Sodium bicarbonate std solns*.—Dry 150–200 g  $NaHCO_3$  over  $H_2SO_4$  24 hr. Weigh designated amts of dried  $NaHCO_3$ , transfer to 1 L vol. flasks with ca 700 mL recently boiled  $H_2O$ , and add 15 mL NaOH soln, (c). Add 200 mL absolute alcohol, mix, cool, and dil. to vol. with boiled  $H_2O$ . Use 4.2955 g for 225 mg  $CO_2$ /100 mL std; 4.7727 g for 250; and 5.2500 g for 275.

(b) *Hydrogen peroxide soln*.—10%. Dil. 20 mL 30%  $H_2O_2$  with 40 mL recently boiled  $H_2O$ .

(c) *Sodium hydroxide soln*.—50%. Transfer 763 g reagent grade NaOH pellets to 1 L Pyrex graduate, add recently boiled  $H_2O$ , cool, and dil. to 1 L. Mix until soln is complete and set aside  $\geq 5$  days until  $Na_2CO_3$  settles, leaving clear soln.

**11.059****Apparatus**

(a) *Carbon dioxide apparatus*.—See Fig. 11:03. Vol. of system is ca 350 mL. (Available from New York Laboratory Supply Co. and Scott Laboratories, Inc., PO Box 3576, San Rafael, CA 94901.) Test all glass joints with vac. tester.

(b) *Vacuum tester*.—High frequency self-contained generator operated from 115 v ac outlet. Consists of adjustable interrupter, vibrating spark gap, condenser, resonator coil, and gap tip.

(c) *Magnetic stirrer with Teflon stirring bar*.—Fisher Flexa-Mix, or equiv., with stirring bars 1–1 $\frac{3}{16}$ " long.

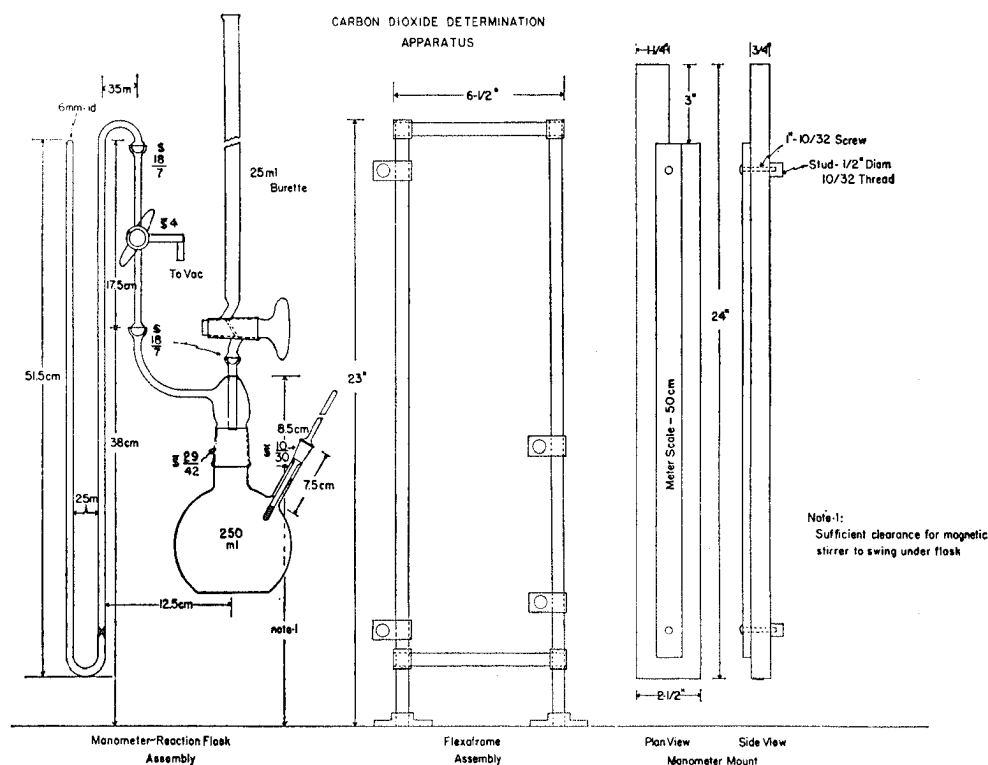

(d) *Vacuum pump*.—Sargent-Welch pump, No. 1399B, or equiv., with motor, single stage, vented exhaust; to be operated with vented exhaust valve open for pumping condensable vapors. Insert 3-way stopcock between pump and app. to allow air to enter system. Ordinary high vac. pump can be used if  $H_2SO_4$  trap with 3-way stopcock is inserted between pump and app. Change acid frequently.

(e) *Silicone grease, high vacuum type*.—Stable to heat and contains no carbon-to-carbon linkages. Grease may be removed from glassware with Varsol or hot kerosene.

**11.060****Calibration of Vacuum System**

(Caution: See 51.015.)

Pipet 50 mL std  $NaHCO_3$  soln and 3 mL 10%  $H_2O_2$  soln into reaction flask, and carefully grease joints. Start mag. stirrer and evacuate system ca 1 min. Close system to pump at 3-way

**FIG. 11:03—Carbon dioxide apparatus; manometric method**

stopcock, gently tap Hg columns, and read manometer to nearest 0.5 mm to obtain initial reading. Hg levels should remain const; changes indicate leak, probably caused by insufficient grease at joints.

Add 10 mL  $\text{H}_3\text{PO}_4$  and continue rapid stirring 5 min. Gently tap Hg columns and read total pressure in cm Hg to nearest 0.5 mm to obtain final reading. Record gas temp. in  $^{\circ}\text{C}$ .

Open 3-way stopcock on app. to pump. Then slowly open 3-way stopcock between pump and app. to let air flow into system. Disconnect app. and thoroly wash inner portion of acid dispensing unit and reaction flask. Rinse with acetone and dry with suction.

Det. total pressure from each  $\text{NaHCO}_3$  std soln in triplicate and calc. av. vol. of system as follows:

From final pressure reading in cm Hg, subtract initial reading and vapor pressure increase due to  $\text{H}_3\text{PO}_4$  effect as given in table:

% Alcohol	Vapor Pressure, cm, Increase Due to $\text{H}_3\text{PO}_4$
0	0.67
5	0.68
10	0.69
15	0.75
20	0.77
25	0.77
50	1.00
75	1.53
100	2.80

Then  $V = 76RTg/MP$ , where  $V$  is system vol. in L;  $R$  is gas const in L-atm./degree/mole, 0.08205;  $T$  is absolute temp., 273 + room temp. in  $^{\circ}\text{C}$ ;  $g$  is g  $\text{CO}_2$  in 50 mL sample;  $M$  is MW of  $\text{CO}_2$  in g; and  $P$  is corrected pressure of  $\text{CO}_2$  in cm Hg.

Calc. correction for Hg displaced in manometer tubing,  $V_m = \pi r^2 L/2$ , where  $L$  is difference in ht of Hg column in cm and  $r$  is internal radius of manometer tubing.

Calibrated vol. of system,  $V_o = V - V_m$ .

In calcg wt  $\text{CO}_2$  in sample, Hg displaced in manometer tubing,  $V_m$ , is added to calibrated vol. of system,  $V_o$ . ( $V = V_o + V_m$ )

#### 11.061 Preparation of Sample

Chill unopened bottle of wine in ice-salt bath to slightly  $<32^{\circ}\text{F}$  (30 min for  $\frac{1}{10}$  gal. bottle and 1 hr for  $\frac{1}{2}$ ). Open bottle and rapidly add 1.5 mL 50% NaOH soln for each 100 mL wine. Quickly close bottle with rubber stopper, remove from bath, and shake several min. Let contents come to room temp.

#### 11.062 Determination

Pipet 50 mL sample and 3 mL 10%  $\text{H}_2\text{O}_2$  into reaction flask, carefully grease joints, and proceed as in 11.060.

From total pressure in cm Hg, subtract vapor pressure of alcohol- $\text{H}_2\text{O}$  and pressure due to  $\text{H}_3\text{PO}_4$  effect. Calc. g  $\text{CO}_2$ /100 mL wine =  $14.327PV/T$ .

To correct for anomalous results which occur with certain fruit wines (e.g., apple), place duplicate sample in 500 mL heavy-wall flask at room temp., shake 1–2 min under ca 69 cm (27") vac., and proceed as above. Subtract value obtained from apparent  $\text{CO}_2$  concn of carbonated wine.

#### Volumetric Method (16)

##### 11.063 Reagents

(a) *Sodium hydroxide std soln.*—0.25N. Prep. as in 50.032–50.034. Stdze as in 50.035 or 50.036, using phthln-thymolphthalein indicator, (e). Restdze daily against std HCl, (b), in presence of 5 mL  $\text{BaCl}_2$  soln, (c), and indicator, (e).

(b) *Hydrochloric acid std soln.*—0.25N. Stdze against std NaOH, (a), using indicator (e).

(c) *Barium chloride soln.*—Dissolve 60–65 g  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$  in 1 L  $\text{H}_2\text{O}$  and neutze to phthln.

(d) *Acid phosphate soln.*—Dissolve 20 g  $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 3 mL  $\text{H}_3\text{PO}_4$ , and dil. to 100 mL.

(e) *Phenolphthalein-thymolphthalein mixed indicator.*—Dissolve 1 g phthln and 0.5 g thymolphthalein in 100 mL alcohol.

#### 11.064

##### Apparatus

See Fig. 11.04. Connect 500 mL special distg flask (rubber stopper and ordinary distg flask may be used) thru ca 8 mm glass tubing to series of 3 Pyrex test tubes, 25  $\times$  200 mm, each fitted at inlet with gas dispersion tube with 12 mm fritted end of coarse porosity and 8 mm stem (Fisher No. 11–138, or equiv.). Connect final exit tube to trapped vac. line or filter pump.

#### 11.065

##### Determination

Connect app. and place test tube receivers in beaker of  $\text{H}_2\text{O}$  at  $<27^{\circ}$ . Pipet 20 mL std 0.25N NaOH into first 2 receivers and 10 mL 0.25N NaOH and 10 mL  $\text{BaCl}_2$  soln into third.

Pipet 50 mL alk. wine, 11.061, into distg flask and add 3 mL 10%  $\text{H}_2\text{O}_2$ , 11.058(b). Add boiling chips (not marble). Attach vac. line to last receiver and slowly increase vac. until bubbling practically stops; then open vac. line fully. (This keeps system under partial vac. so that stoppers will not be blown out on heating by sudden surge of steam or  $\text{CO}_2$ .) Add ca 35 mL acid phosphate soln to dropping funnel and carefully admit ca 30 mL into distg flask. Agitate flask gently to mix acid and sample.

Heat gently and when  $\text{CO}_2$  evolution slows, heat vigorously. After few mL of liq. distils and top of first receiver is warm, all  $\text{CO}_2$  will have been driven into receivers. Close vac. line between trap and receivers and slowly admit air thru dropping funnel until pressure equilibrium is reached.

Transfer contents and rinsings of first 2 receivers and dispersion tubes into titrn flask. (Also add contents of third if  $\text{BaCO}_3$  has pptd.) Add 50 mL  $\text{BaCl}_2$  soln and titr. with std HCl to phthln end point.

Wt  $\text{CO}_2$  in g/100 mL = [(mL NaOH  $\times$  normality) – (mL HCl  $\times$  normality)]  $\times$  0.022  $\times$  (100/50)  $\times$  1.015.

#### Enzymatic Method (17)—Official Final Action

##### 11.066

##### Reagent

*Carbonic anhydrase soln.*—Prep. aq. soln contg ca 1 mg enzyme/mL. Soln is stable ca 2 weeks in refrigerator.

##### 11.067

##### Determination

Cool sample to  $\leq 0^{\circ}$ , so that it can be pipetted without loss of  $\text{CO}_2$ . With automatic 25 or 30 mL pipet with Teflon stopcock, dispense aliquot of 0.1N NaOH into beaker. Rinse 20 mL pipet with sample to prevent warming sample with possible loss of  $\text{CO}_2$ . Pipet sample with tip submerged just below surface of NaOH in beaker. Add 3–4 drops enzyme, and place beaker under glass and calomel electrodes. Titr. to pH 8.45 with 0.1N  $\text{H}_2\text{SO}_4$  from 5 mL buret graduated in 0.01 mL.

To correct for presence of acids other than  $\text{H}_2\text{CO}_3$ , place 50 mL wine in 500 mL heavy-wall flask at room temp. and agitate 1 min under vac. of ca 27" (69 cm). Titr. 20 mL to pH 7.75 with 0.1N NaOH as above. Subtract mL used from that used in first titrn. Calc. as follows: (Net mL NaOH  $\times$  normality – mL  $\text{H}_2\text{SO}_4$   $\times$  normality)  $\times$  100  $\times$  44/mL sample = mg  $\text{CO}_2$ /100 mL wine.

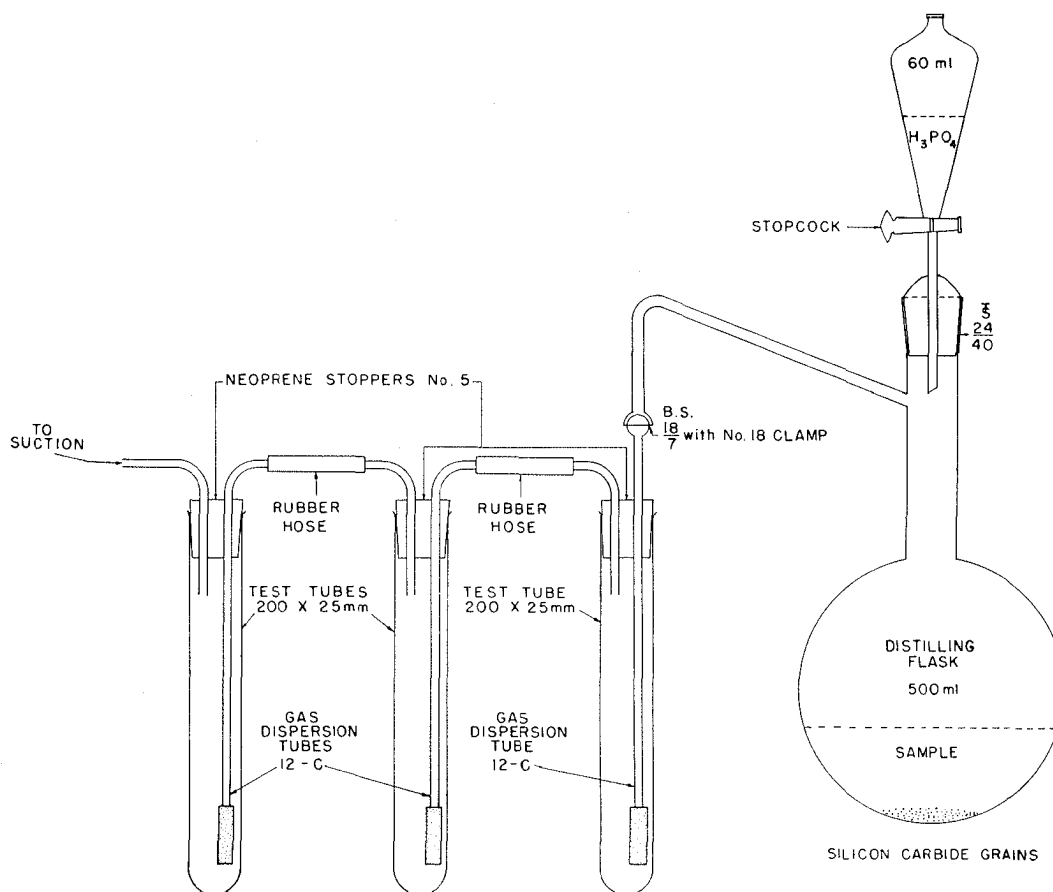

FIG. 11:04—Carbon dioxide apparatus; volumetric method

**PRESERVATIVES****11.068 Preservatives—Official Final Action**

See also Chap. 20.

**11.069 Sulfurous Acid (18)—Official Final Action**

Proceed as in 20.108, using 100–300 mL sample. Report results as mg  $\text{SO}_2/\text{L}$ . (As  $\text{SO}_2$  in wine is unstable, give sample no preparatory degassing treatment and expose to air for min. time prior to detn.)

**Sorbic Acid—Official Final Action (19)****Ultraviolet Method****11.070****Apparatus**

- (a) Cash electric still.—See 11.038(b) and Fig. 11:02.  
 (b) Ultraviolet spectrophotometer.

**11.071****Reagents**

- (a) Hydrochloric acid.—0.1N. Dil. 8.2 mL HCl to 1 L with  $\text{H}_2\text{O}$ .  
 (b) Sorbic acid std soln.—1.0 mg/mL. Accurately weigh 1.340 g K sorbate (equiv. to 1.000 g sorbic acid) in 1 L vol. flask, and dissolve and dil. to vol. with  $\text{H}_2\text{O}$ . Soln is stable several days when refrigerated.

**11.072****Preparation of Standard Curve**

Pipet 0, 10, 20, 30, and 40 mL sorbic acid std soln into sep. 100 mL vol. flasks, and dil. to vol. with  $\text{H}_2\text{O}$ . Pipet 2 mL of each soln into sep. 200 mL vol. flasks, add 0.5 mL 0.1N HCl, and dil. to vol.

with  $\text{H}_2\text{O}$ . Read  $A$  at 260 nm in 1 cm cell and plot  $A$  against concn.

**11.073****Determination**

Pipet 2 mL wine sample into Cash still. Rinse in with 2–3 mL  $\text{H}_2\text{O}$ . Steam distil into 200 mL vol. flask contg 0.5 mL 0.1N HCl. Collect ca 190 mL distillate; dil. to vol. with  $\text{H}_2\text{O}$ . Read  $A$  at 260 nm in 1 cm cell. Det. concn from std curve.

**Colorimetric Method****11.074****Reagents and Standard Curve**

See 20.099(a)(2)–(d) and 20.100.

**11.075****Determination**

Pipet 2 mL wine sample into Cash still, 11.038(b). Rinse in with 2–3 mL  $\text{H}_2\text{O}$ . Steam distil ca 190 mL into 200 mL vol. flask. Dil. to vol. with  $\text{H}_2\text{O}$ . Proceed as in 20.100, beginning "Pipet 2 mL each soln . . ." Det. concn sorbic acid from std curve.

**Diethylcarbonate (20)—Official Final Action****11.076****Reagents**

(a) Carbon disulfide.—Treat 200 mL  $\text{CS}_2$  with 20 mL fuming  $\text{HNO}_3$ ; then wash with 20 mL portions  $\text{H}_2\text{O}$  until wash is neut. to pH paper. (Caution: See 51.026, 51.031, and 51.048.)

(b) Diethylcarbonate std soln.—0.5 mg/mL. Dissolve 50 mg diethylcarbonate in 100 mL alcohol. (If sample contains <1 or >10 mg diethylcarbonate/L, change concn appropriately.)

## 11.077

## Apparatus

Use gas chromatograph with H flame ionization detector. Column: 1.8 m (6')  $\times$   $\frac{1}{8}$ " od stainless steel packed with 15% trimethylolpropanetripropylargonate (Analabs, Inc.) on 60–100 mesh Celite 545 (10–20% Carbowax 20M (Analabs, Inc.) on 60 mesh Firebrick C-22 (Analabs, Inc.) may be used, but yields poorer sepn). GLC conditions: temps ( $^{\circ}$ )—column 80, injection port 180, detector 200; flow rates (mL/min)—N carrier gas 35, H 35, air 400; recorder 1–2.5 mv. Diethylcarbonate retention time is ca 15 min.

## 11.078

## Determination

Measure 100 mL sample in graduate and transfer to 250 mL separator. Add 1 mL alcohol and 20 mL  $\text{CS}_2$ , and shake  $\geq 1$  min. Let sep., transfer portion of lower layer to small test tube, and centr. 2–3 min at 2000 rpm to clarify.

Slowly (5 sec) inject 5  $\mu\text{L}$  clear soln from 10  $\mu\text{L}$  syringe. Designate peak area obtained as PA. Likewise, inject 5  $\mu\text{L}$  wine prep'd by adding 1 mL diethylcarbonate std soln to 100 mL wine. Proceed with detn, beginning "... transfer to 250 mL separator." Designate peak area obtained as PA'.

$$\text{mg Diethylcarbonate/L} = (C \times PA \times 10)/(PA' - PA),$$

where  $C$  = mg diethylcarbonate/mL std soln.

After each detn increase column temp. to  $200^{\circ}$  for  $\geq 20$  min to purge other extd compds from column.

## FLAVORS

## Coumarin (1,2-Benzopyrone) (21)

Gas Chromatographic Method  
Official First Action

## 11.079

## Reagents and Apparatus

(a) *Coumarin std soln.*—0.5 mg/mL alcohol. Accurately weigh 100 mg coumarin (Eastman Kodak No. 79, or equiv.), dissolve in alcohol in 200 mL vol. flask, and dil. to vol.

(b) *Gas chromatograph.*—With flame ionization detector and 1.8 m (6')  $\times$  2 mm id glass column packed with 10% SP-1000 (Carbowax 20 M-TPA) on 100–120 mesh Chromosorb W AW (No. 01-1962, Supelco, Inc.). Operating conditions: He (use gas purifier filter) carrier gas flow rate—30 mL/min; temps ( $^{\circ}$ )—column 180, injector and detector 200. Adjust GLC operating parameters to obtain optimum sepn and efficiency, with coumarin retention time of ca 15 min.

## 11.080

## Determination

Add 100 mL sample to each of two 250 mL separators. Add 1.0 mL coumarin std soln to one (spiked sample) and 1.0 mL alcohol to other (unspiked sample). Mix thoroly and ext with 20 mL  $\text{CHCl}_3$ , shaking vigorously 2 min. Let layers sep. and drain ca 10–12 mL  $\text{CHCl}_3$  layer into centr. tube. Swirl stirring rod in tube to aid in breaking emulsion and freeing  $\text{CHCl}_3$ . Centr., if necessary, to clarify. Inject 5  $\mu\text{L}$  clear  $\text{CHCl}_3$  ext onto GLC column. Average 3 values for calcn.

$$\text{mg Coumarin/L} = [U/(S - U)] \times 0.5 \times (1000/100),$$

where  $U$  = peak ht of unspiked sample,  $S$  = peak ht of spiked sample, and 0.5 = mg coumarin added to 100 mL spiked sample.

 $\beta$ -Asarone (cis-2,4,5-Trimethoxy-1-propenylbenzene)Gas Chromatographic Method (22)  
Official First Action

## 11.081

## Apparatus and Reagents

(a) *Gas chromatograph.*—With flame ionization detector and 1.8 m  $\times$  2 (id) mm glass or stainless steel column packed with

10% SP-1000 (No. 01-1872, Supelco, Inc.) on Chromosorb W HP 80/100. Typical operating conditions—temps ( $^{\circ}$ ): column 180, detector and injection port 200; He carrier gas (with purifier filter) flow rate 40 mL/min. Retention times of Et palmitate and  $\beta$ -asarone are ca 5 min and 6 min, resp.

(b) *Ethyl palmitate internal std soln.*—Prep. 1 mg/mL soln in hexane.

(c)  *$\beta$ -Asarone std soln.*—Prep. 1 mg/mL soln in alcohol. ( $\beta$ -asarone is available on special order as No. TT150 from Fritzsche, Dodge, & Olcott, Inc., 76 Ninth Ave, New York, NY 10011.)

## 11.082

## Preparation of Standard Curve

Prep. std solns contg 1, 2, 3, 4, and 5 mg  $\beta$ -asarone/L by adding 100, 200, 300, 400, and 500  $\mu\text{L}$  std soln to sep. 100 mL vol. flasks contg ca 90 mL 20% alcohol. Mix, dil. to vol. with 20% alcohol, and remix.

Transfer entire soln, rinsing with 50 mL  $\text{H}_2\text{O}$ , to simple distg app. and distil ca 100 mL. Transfer distillate to 250 mL separator, add 100 mL satd soln of NaCl, and mix. Add 10 mL hexane, shake vigorously 2 min, and let sep. Drain and discard aq. soln. Dry inside of drain tube of separator with tissue or pipe cleaner. Collect hexane in calibrated centr. tube (10  $\pm$  0.5 mL should be recovered). Add 200  $\mu\text{L}$  Et palmitate internal std soln and mix well. Chromatograph 5  $\mu\text{L}$  of each ext and plot std curve of original concn of mg  $\beta$ -asarone/L against peak ht ratio of  $\beta$ -asarone:Et palmitate.

## 11.083

## Determination

Distil 100 mL sample and 50 mL  $\text{H}_2\text{O}$ , collecting 100 mL distillate. Transfer distillate, ext with 10 mL hexane, and chromatograph 5  $\mu\text{L}$  as in 11.082. Check for presence of  $\beta$ -asarone and Et palmitate. If there is no  $\beta$ -asarone peak,  $\beta$ -asarone is not present at 0.5 mg/L level. If  $\beta$ -asarone is present in range of std curve and no Et palmitate is present, add 200  $\mu\text{L}$  Et palmitate internal std soln to hexane ext, mix, and rechromatograph. Use ratio of peak hts to det.  $\beta$ -asarone concn from std curve. If  $\beta$ -asarone peak is off scale, dil. hexane ext with hexane to 1–5 mg  $\beta$ -asarone/L, add internal std soln, mix, and rechromatograph. If peak is present in ext with same retention time as Et palmitate, use peak hts directly to det.  $\beta$ -asarone concn from std curve prep'd from peak hts.

See 12.019, 12th ed.

### 12.020 ★ Total Malic Acid (Laevo and Inactive) ★ Official First Action

See 12.020, 12th ed.

### 12.021 ★ Laevo Malic Acid—Official First Action ★

See 12.021, 12th ed.

### 12.022 Volatile Acidity—Official Final Action

See 11.041.

### 12.023 Esters—Official Final Action

Proceed as in 9.125, collecting ca 300 mL distillate.

#### Methyl Anthranilate—Official Final Action

##### Colorimetric Method (1)

(Applicable to samples contg  $< 500$  mg/L)

### 12.024

#### Reagents

(a) *Dilute hydrochloric acid.*—Dil. 83 mL HCl to 1 L with  $H_2O$ .

(b) *Sodium nitrite soln.*—Dissolve 2 g  $NaNO_2$  in 100 mL  $H_2O$ .

(c) *Hydrazine sulfate soln.*—Dissolve ca 3 g  $N_2H_4 \cdot H_2SO_4$  in 100 mL  $H_2O$ .

(d) *Sodium- $\alpha$ -naphthol-2-sulfonate soln.*—Dissolve 5 g of the sulfonate in 100 mL  $H_2O$ .

(e) *Sodium carbonate soln.*—Dissolve 25 g  $Na_2CO_3$  in 75 mL  $H_2O$ .

(f) *Methyl anthranilate std soln.*—1 mg/mL. Dissolve 0.25 g Me anthranilate in 60 mL alcohol and dil. to 250 mL with  $H_2O$ .

### 12.025

#### Apparatus

(a) *Steam generator filled with  $H_2O$ .*—Oil can holding 1 gal. (ca 4 L) serves purpose.

(b) *Distillation flask.*—Kjeldahl flask, ca 750 mL, with shortened neck, ca 25 cm over-all ht.

★ Surplus method—see inside front cover.

(c) *Spray tube*.—Glass tube with small perforated bulb at end, passing thru rubber stopper and reaching to bottom of distn flask.

(d) *Connecting bulb*.—Kjeldahl bulb with bent connecting tube.

(e) *Worm condenser*.—With H<sub>2</sub>O jacket 25–30 cm long, and outlet tube reaching bottom of 500 mL erlenmeyer receiving flask.

## 12.026

### Determination

Place just enough H<sub>2</sub>O in receiving flask to seal end of extended condenser tube. Place 10–100 mL sample in distn flask and add, if necessary, H<sub>2</sub>O to make 100 mL. Insert stopper carrying spray tube and connecting bulb, and connect with condenser and receiving flask. Immerse distn flask in H<sub>2</sub>O bath near bp to level of contents. When sample reaches temp. of bath, connect to steam generator with H<sub>2</sub>O boiling and rapidly pass steam thru sample until ca 300 mL distillate collects.

Disconnect app. and wash out condenser with little H<sub>2</sub>O. Add 25 mL dil. HCl and 2 mL NaNO<sub>2</sub> soln to distillate, mix well, and let stand exactly 2 min. Add 6 mL N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>SO<sub>4</sub> soln and mix well 1 min, so that liq. comes in contact with all parts of flask that soln may have touched when it contained free HNO<sub>2</sub>. Keep liq. in flask in rapid motion, quickly add 5 mL Na  $\alpha$ -naphthol-2-sulfonate soln, and then immediately add 15 mL Na<sub>2</sub>CO<sub>3</sub> soln. Dil. colored soln to 500 mL with H<sub>2</sub>O, mix, and compare color of portion with color of std, or set of stds, prepd as nearly as possible at same time. Calc. results as mg Me anthranilate/L.

### Gravimetric Method (2)

(Applicable to samples contg  $\geq 500$  mg/L)

## 12.027

### Reagents and Apparatus

(a)  $\alpha$ -Naphthol soln.—Dissolve 0.2 g  $\alpha$ -naphthol in 100 mL 30% alcohol.

(b) Sodium bicarbonate soln.—Dissolve 8.4 g NaHCO<sub>3</sub> in 100 mL H<sub>2</sub>O.

(See 12.024 for reagents and 12.025 for app.)

## 12.028

### Determination

Place sample contg 50–125 mg Me anthranilate in distn flask and dil., if necessary, to 100 mL with H<sub>2</sub>O. Steam distil as in 12.026, collecting ca 400 mL distillate.

Wash out condenser with little H<sub>2</sub>O and dil. distillate to 500 mL. Mix, and to 200 mL aliquot add 5 mL dil. HCl and 5 mL NaNO<sub>2</sub> soln. Mix well and let stand 1 min. Mix 25 mL  $\alpha$ -naphthol soln and 6 mL NaHCO<sub>3</sub> soln, pour diazotized soln into mixt., and let stand 10 min. Fold 2 Whatman 1 or S&S 595 papers, 12.5 cm diam., and det. difference in their wts by placing one on each pan of balance and counterpoising with added wts. Place heavier inside lighter paper, fit into funnel, and moisten. Pour mixt. thru this filter and wash ppt 7 or 8 times, using total of ca 100 mL H<sub>2</sub>O. Fill filter only to ca 1 cm from top. Place funnel carrying filter and washed ppt in oven, and dry ca 10 min at 100°. Sep. and dry filter papers ca 1 hr at same temp. Det. difference in wts, dry again, weigh again, and repeat until difference in wts remains const. (Const difference in wts – original difference in wts of 2 papers)  $\times$  0.4935 = wt anthranilic acid ester, as Me anthranilate. Report as g/L.

## 12.029 Benzaldehyde (3)—Official Final Action

Measure 500 mL beverage, 100 mL flavoring sirup, or 10–25 mL flavor into distg flask. Add 32 mL alcohol, and in case of sirup or flavor, ca 300 mL H<sub>2</sub>O, and proceed as in 19.101.

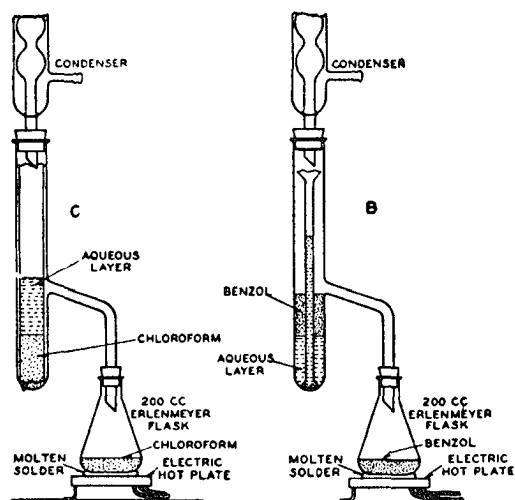

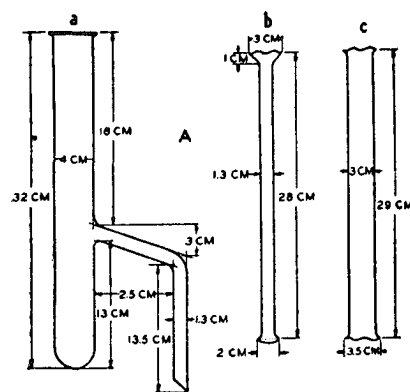

FIG. 12.01—Continuous extraction apparatus

## 12.030 ★ Gamma Undecalactone ★ (4)—Official Final Action

See 8.030, 10th ed.

## 12.031 Essential Oils—Official First Action

See 19.128.

## Caffeine (5)—Official First Action

## 12.032

### Apparatus

(a) *Continuous extractor*.—Similar to Fig. 12.01, with outer part of 43 mm od tubing, 45 cm long, with side tube 25 cm above bottom, fitted with drip tip  $\frac{1}{8}$  24/40 joint; inner tube of 30 mm od tubing, 39–40 cm long; receiver is 250 mL erlenmeyer with  $\frac{1}{8}$  24/40 joint.

(b) *Filtering device*.—Glass buchner with 30 mm fine fritted disk and 45 mm high side wall, fitted with 2 interchangeable rubber stoppers, one to fit suction flask, other to fit 20  $\times$  150 mm side arm test tube.

## 12.033

### Reagents

(a) *Phosphomolybdic acid soln*.—Dissolve 10 g phosphomolybdic acid in ca 25 mL warm H<sub>2</sub>O, cool to room temp., and dil. to 50 mL with H<sub>2</sub>O. Let stand overnight and filter thru S&S 589 blue ribbon paper. Store in dark.

★ Surplus method—see inside front cover.

(b) *Caffeine std soln.*—1 mg/mL. Weigh 100 mg caffeine alkaloid, dissolve in  $H_2O$ , and dil. to 100 mL.

**12.034****Extraction**

(Caution: See 51.011, 51.040, and 51.056.)

Place few glass beads in receiver, assemble extractor, and add 210–220 mL  $CHCl_3$  to inner tube. Measure 150 mL sample in graduate and make alk. with ca 2 mL 10N NaOH, using litmus paper as indicator. Place funnel in top of extractor and add sample to inner tube, letting  $CHCl_3$  in outer tube overflow into receiver. Remove funnel and attach condenser. If tip of condenser is >2 cm above inner tube, place small funnel with 2–3 cm stem in top of inner tube to prevent splashing. Ext 2 hr, keeping steady stream of solv. flowing from condenser.

Remove hot plate and let receiver cool somewhat. Disconnect condenser and tilt extractor to permit as much  $CHCl_3$  as possible to flow into receiver without letting any aq. phase rise into space between the 2 parts of extractor. Transfer entire contents of extractor to separator. Rinse extractor with  $H_2O$  and discard. Attach outer part of extractor to receiver and to condenser, and heat carefully until vol.  $CHCl_3$  in receiver is 30–40 mL. Do not let soln bump or foam into extractor. Cool somewhat, drain  $CHCl_3$  ext from separator into receiver, and distil  $CHCl_3$  into extractor as before until 10–15 mL remains in receiver. Cool  $CHCl_3$  in receiver and transfer to weighed 50 mL beaker, rinsing with several small portions  $CHCl_3$ . Evap. to dryness and weigh.

If residue wt is  $\leq 5$  mg, dissolve in 5 mL  $H_2O$ , filter thru very small circle of paper into 50 mL beaker, and wash beaker and paper with 5 mL  $H_2O$ ; if wt is >5 mg, dissolve, using several successive 5 mL portions  $H_2O$ , and filter into vol. flask (25 mL for residue of  $\leq 15$  mg; 50 mL if >15 mg). Dil. to vol. with  $H_2O$  and mix.

**12.035****Determination**

Place soln or aliquot contg 2–5 mg residue in 50 mL beaker; add 1 mL HCl (1+1) and enough  $H_2O$  to make 11 mL. Cover with watch glass and warm on steam bath. Add 2 mL phosphomolybdic acid soln dropwise with stirring, re-cover, and continue heating 20 min. Filter hot soln thru buchner into suction flask, and wash ppt and funnel with three 5 mL portions HCl (1+9), using policeman to scrub down walls of beaker. Aspirate dry. Wipe away any aq. soln at tip of buchner, change stopper to fit side arm test tube, and assemble. Dissolve ppt in three 5 mL portions acetone. Wash tip of buchner with few drops acetone, transfer to 25 mL vol. flask, and dil. to vol. with acetone. Det. A at 440 nm against acetone, and det. mg caffeine from std curve. Calc. to g/100 mL.

**12.036****Preparation of Standard Curve**

Pipet 0, 1, 2, 3, 4, and 5 mL portions std caffeine soln into 50 mL beakers and proceed as in 12.035, beginning "... add 1 mL HCl (1+1) ...". Plot A against mg caffeine.

**Alternative Method (6)—Official First Action****12.037****Reagents**

(a) *Reducing soln.*—Dissolve 5 g  $Na_2SO_3$  and 5 g KSCN in  $H_2O$  and dil. to 100 mL.

(b) *Dilute phosphoric acid soln.*—Dil. 15 mL  $H_3PO_4$  to 85 mL with  $H_2O$ .

(c) *Sodium hydroxide soln.*—Dissolve 25 g NaOH in 75 mL  $H_2O$ .

(d) *Caffeine std soln.*—1 mg/mL  $CHCl_3$ . Purify caffeine, if necessary, by recrystn and/or sublimation. Dissolve 100 mg in  $CHCl_3$  and dil. to 100 mL with  $CHCl_3$ .

**12.038****Preparation of Standard Curve**

Prep. dild std solns contg 0.10, 0.25, 0.50, 1.00, 1.50, and 2.00 mg caffeine/100 mL  $CHCl_3$ . Det. wavelength of max. A of 1 mg/100 mL soln at ca 276.5 nm and det. A of all solns at this wavelength against  $CHCl_3$  in 1 cm matched cells. Plot A against concn or calc. factor = 10/av. reading for 1 mg/100 mL std calcd from all readings.

**12.039****Determination**

Remove any gas by pouring sample back and forth in beakers. Pipet 10 mL sample into 125 mL separator, add 5 mL 1.5%  $KMnO_4$  soln, and mix. After exactly 5 min, add 10 mL reducing soln and mix. Add 1 mL dil.  $H_3PO_4$  soln, mix, add 1 mL NaOH soln, mix, and ext with 50 mL  $CHCl_3$  1 min. After sepn, drain lower layer thru 7 cm paper into 100 mL g-s vol. flask. Add 2–3 mL  $CHCl_3$  to separator and drain thru paper to rinse separator stem. Wash paper with 2–3 mL  $CHCl_3$ . Re-ext soln with 40 mL  $CHCl_3$  and wash stem and paper as before. Dil. to vol. with  $CHCl_3$ . Det. A of this soln at wavelength of max. A against  $CHCl_3$ . Det. amt caffeine from std curve or from factor and calc. mg/100 mL beverage.

**Spectrophotometric Method (7)—Official First Action**

(Method is preferable to 12.037–12.039 when only few samples are to be analyzed. Use 12.032–12.036 for complex mixts requiring extensive cleanup.)

**12.040****Apparatus**

*Chromatographic tubes.*—Glass, ca 25 × 250 mm.

**12.041****Reagents**

(Use  $CHCl_3$  and ether washed with  $\frac{1}{2}$  vol.  $H_2O$  thruout.)

*Caffeine std solns.*—(1) *Stock soln.*—See 12.037(d). (2) *Working solns.*—Prep. dilns of stock soln contg 0.25, 0.50, and 0.75 mg caffeine/50 mL  $CHCl_3$ . Check factor, 12.045, frequently to minimize instrument variations.

**12.042****Preparation of Sample**

Remove any gas by pouring sample back and forth in beakers. Pipet appropriate amt sample (5 or 10 mL) into 250 mL beaker. Evap. to near dryness on steam bath. Dissolve residue in 5 mL  $NH_4OH$  (1+2) and heat 2 min on steam bath. Remove from heat, add 6 g Celite 545, and mix carefully to homogeneity before prep column.

**12.043****Preparation of Columns**

(a) *Column I.*—Carefully mix 2 mL 4N  $H_2SO_4$  with 2 g Celite 545, place in chromatgc tube over glass wool plug, and tamp to uniform mass with moderate pressure. Top with glass wool plug to minimize damage to column surface.

(b) *Column II.*—(1) *Layer 1.*—Carefully mix 3 g Celite 545 with 2 mL 2N NaOH, transfer to tube over glass wool plug, and tamp to uniform mass. (2) *Layer 2.*—Transfer prepd sample and Celite mixt. to column directly over layer 1 and tamp. Dry-wash beaker with 1–2 g dry Celite and transfer to column. Tamp to uniform mass and top column with glass wool pad.

**12.044****Determination**

Mount column II over column I. Pass 150 mL ether thru column II and into column I, using initial portion of ether to rinse sample beaker. Drain well and remove column II. Pass addnl 50 mL ether thru column I and drain well. Pass 50 mL  $CHCl_3$  thru column I, using initial portion to wash tip of column II. Collect

eluate in 50 mL vol. flask and adjust vol. to 50 mL. Read  $A$  of  $\text{CHCl}_3$  soln at 276 nm against  $\text{CHCl}_3$  ref., using Beckman Model DU, or equiv., spectrophtr, with 1 cm silica cells. If necessary, adjust concns to acceptable levels by dilg with  $\text{CHCl}_3$ .

**12.045****Calculations**

Factor  $F$  = mg caffeine in 50 mL std soln/ $A$ .

mg Caffeine in sample =  $F \times A$ .

Express results as mg caffeine/100 mL beverage.

***Dihydroanethole, Dihydrosafrole, Isosafrole,  
Methyl Salicylate, and Safrole (8)***  
**Official Final Action**

(Quant. for Me salicylate; semiquant. for other compds)

**12.046****Reagents**

All solvs must be chromatographically pure and meet following test: Conc. 500 mL solv. to 10 mL in evaporative concentrator and chromatograph on prepd column with instrument set at max. sensitivity to be used during analysis; 5  $\mu\text{L}$  concd solv. must not show any trace of peaks beyond solv. front. (Distd-in-glass solvs generally conform to test stds.) Purify solvs not passing test as in (a) and (b).

(a) *Methanol*.—Anhyd. Reflux 1 L with 10 g KOH and 25 g Zn dust 3 hr. Distil, discarding first 100 mL. (Caution: See 51.011, 51.037, and 51.066.)

(b) *Chloroform*.—Redistil at bp. Add 1% MeOH if stored. (Caution: See 51.056.)

(c) *Flavor std soln*.—(1) *Stock soln*.—79 mg/mL (10,000 ppm). Dil. 7.90 g compd to 100 mL with MeOH. (2) *Working soln*.—7.9 mg/mL (1000 ppm). Dil. 1 mL stock soln to 10 mL with MeOH.

(d) *Internal std solns*.—Use *n*-decyl alcohol for Me salicylate detn and *m*-tolyl acetate for detn of other compds. Prep. stock and working std solns as in (c).

(e) *Defoaming agent*.—Dow Corning Antifoam A, or equiv.

**12.047****Apparatus**

(a) *Steam distillation apparatus*.—500 mL r-b flask with long neck,  $\text{\text{F}}$  24/40 joint; adapter,  $\text{\text{F}}$  24/40 inner joint at bottom and at side at 75° angle and with  $\text{\text{F}}$  24/40 joint at top; gas inlet tube, 30 cm,  $\text{\text{F}}$  24/40 inner joint and perforated 8 mm bulb at dispersion tip; condenser, 200 mm  $\text{\text{F}}$  24/40 joint; and adapter, vac. takeoff type with extended lower tube, straight joint  $\text{\text{F}}$  24/40.

(b) *Concentrator*.—Evaporative concentrator, Kuderna-Danish type, 500 mL, with 10 mL receiving flask.

(c) *Gas chromatograph*.—With flame ionization detector, and operating parameters as follows: 1.8 m (6')  $\times$  4 mm id glass column, coiled or U-shaped, packed with 15% polypropylene glycol adipate (Reoplex 400) on 60–80 mesh Gas-Chrom P (w/w); temps (°)—column 130 (isothermal), detector 220, injection port 180; N carrier gas 40 psi at ca 90 mL/min. Column may be programmed over range 90–150° at 2°/min.

**12.048**

***Determination of Relative  
Retention Time (RT)***

(a) *Methyl salicylate*.—Pipet 1 mL working std soln and 1 mL *n*-decyl alcohol working internal std soln into 10 mL vol. flask, and dil. to vol. with MeOH.

(b) *Other flavor compounds*.—Pipet 1 mL appropriate working std soln and 5 mL *m*-tolyl acetate working internal std soln into 10 mL vol. flask, and dil. to vol. with MeOH.

Inject 3–5  $\mu\text{L}$  into gas chromatograph. Set sensitivity and attenuation controls to provide peak ht  $\leq 80\%$  of chart scale.

Calc.  $RT$  = time for std component peak to emerge/time for internal std peak to emerge. (Time is measured from emergence of solv. front.) Use  $RT$  to identify component peak in sample. Calc. peak area ( $PA$ ).

**12.049****Determination**

(Analyze samples on same day and under same conditions used for detn of  $RT$ . Caution: See 51.011 and 51.056.)

(a) *Methyl salicylate*.—Place 200 mL sample, degassed if necessary, in 500 mL r-b flask; add 10 mL MeOH, few SiC chips, and small amt defoamer. Add 1 mL *n*-decyl alcohol working internal std, (d), and attach to distg app. not connected to steam generator. Bring sample to incipient boil, connect steam generator, and collect 90 mL distillate at ca 2 mL/min in 100 mL Nessler tube or graduate contg 10 mL MeOH to cover delivery tube outlet. Rinse condenser and delivery tube into distillate twice with 5 mL MeOH. Quant. transfer distillate to 250 mL separator. Add 50 mL satd NaCl soln and ext with 25, 25, and 10 mL  $\text{CHCl}_3$  by carefully shaking 5 min for each extn. Filter  $\text{CHCl}_3$  thru 12.5 cm Whatman No. 30 paper contg 3–5 g  $\text{Na}_2\text{SO}_4$  into 500 mL evaporative concentrator. Wash separator and paper with 10–15 mL  $\text{CHCl}_3$  into concentrator. Add few SiC chips and evap. on steam bath to ca 7 mL. Cool, and dil. to 10.0 mL with  $\text{CHCl}_3$ . Det. Me salicylate by GLC as in 12.048.

mg Me salicylate/mL or ppm =  $(PA/PA')(PA_1'/PA_1) \times C \times F$ , where  $PA$  and  $PA'$  are peak areas of sample and std solns, resp.,  $PA_1'$  and  $PA_1$  are peak areas of internal std in std and sample solns, resp.,  $C$  = concn Me salicylate in working std soln (7.9 mg/mL or 1000 ppm), and  $F$  = diln factor (1/20).

(b) *Other flavor compounds*.—Proceed as in (a) except use 5.0 mL *m*-tolyl acetate working internal std soln, (d), and collect 150 mL distillate at 5 mL/min.

**Benzoate, Caffeine, and Saccharin in Soda Beverages**

**High Performance Liquid Chromatographic Method (9)**  
**Official First Action**

**12.050****Principle**

Saccharin, benzoate, and caffeine are simultaneously quantitated in soda beverages by HPLC, using HOAc soln as mobile phase. Artificial colors and sorbates may interfere. Beverage blanks contg color or sorbate should be run to assure non-interference by these compds. In absence of beverage blanks, analyze samples with 2 different mobile phases with different amts of isopropanol and/or HOAc or by method of std additions. Adjustment of mobile phase (% acid and/or % isopropanol) can resolve interfering peaks.

**12.051****Apparatus and Reagents**

(a) *Liquid chromatograph*.—Waters Associates ALC/GPC with 6000A solv. delivery system and model U6K injector, or equiv., UV 254 nm detector, 10 mv strip chart recorder (Houston Omni Scribe, or equiv.), and  $\mu$  Bondapak  $\text{C}_{18}$  column, 300  $\times$  4 (id) mm, or equiv., with flow rate of 2 mL/min. Detector sensitivity: adjustable from 0.02–0.05 auFs.

(b) *Mobile phase*.—20% HOAc (v/v) buffered to pH 3.0 with satd NaOAc soln. Modify with 0–2% isopropanol to obtain baseline resolution and retention times of stds from mixed std soln in ca 10 min. Soln is stable 2–3 days. Degas prior to use. (Alternatively, lower HOAc concn may be used, and, for some columns, may be necessary to obtain retention and/or resolution. Lower HOAc concn solns give longer retention times, e.g. 5% HOAc elutes compds in 35 min.)

(c) *Std solns.*—Prep. individual std solns from compds of known purity to give following concns: Na saccharin, 0.50 mg/mL; caffeine, 0.050 mg/mL; and Na benzoate, 0.50 mg/mL. Use these solns to det. sensitivity for detector response and retention times of individual stds.

(d) *Mixed std solns.*—Prep. soln contg 0.50 mg/mL Na saccharin, 0.50 mg/mL Na benzoate, and 0.050 mg/mL caffeine. Use this soln to optimize HPLC conditions for complete resolution of the 3 compds and to quantitate.

**12.052****Preparation of Sample**

(a) *Carbonated beverages.*—Decarbonate by agitation or ultrasonic treatment. If free of particulate matter, inject directly.

(b) *Beverages containing particulate matter.*—Filter thru Milipore filter (0.45  $\mu$ ), discarding first few mL filtrate. If large amt of particulate matter is present, centrf. prior to filtering. Inject filtered soln directly.

**12.053****Determination**

Inject known vol. (ca 10  $\mu$ L) of mixed std soln in duplicate. Peak hts should agree within  $\leq 2.5\%$ . Inject known vol. (ca 10

$\mu$ L) of prepd sample in duplicate. Measure peak hts of std and sample components.

$$\% \text{ Compd} = C' \times (H/H') \times (V'/V) \times 0.1,$$

where  $C'$  = concn of std in mg/mL;  $H$  and  $H'$  = av. peak ht of sample and std, resp.;  $V$  and  $V'$  = vol. injected in  $\mu$ L of sample and std, resp.

**12.054 Alginates in Chocolate Beverage Products**  
**Official Final Action**

See 13.058.

## 13. Cacao Bean and Its Products

### 13.001 Preparation of Sample—Procedure

(a) *Powdered products*.—Mix thoroly and preserve in tightly stoppered bottles.

(b) *Chocolate products*.—(1) Chill ca 200 g sweet or bitter chocolate until hard, and grate or shave to fine granular condition. Mix thoroly and preserve in tightly stoppered bottle in cool place. Alternatively—

(2) Melt ca 200 g bitter, sweet, or milk chocolate by placing in suitable container and partly immersing container in bath at ca 50°. Stir frequently until sample melts and reaches temp. of 45–50°. Remove from bath, stir thoroly, and while still liq., remove portion for analysis, using glass or metal tube, 4–10 mm diam., provided with close-fitting plunger to expel sample from tube, or disposable plastic syringe.

### 13.002 Moisture (1)—Official First Action

Dry 2 g prepd sample, **13.001**, to const wt in Pt dish in air oven at 100°. (Al dish may be used when ash is not detd on same sample.) Report loss in wt as H<sub>2</sub>O.

#### *Karl Fischer Method (2)—Official Final Action*

(Applicable to milk chocolate and confectionary coatings)

### 13.003 Apparatus and Reagents

(a) *Karl Fischer titration assembly*.—Manual or automatic, with stirrer.

(b) *Syringes*.—1 mL with needle end cap (0–40 unit insulin type is satisfactory) and 10 mL without needle (disposable plastic type is satisfactory).

(c) *Karl Fischer reagent*.—See **32.048(a)**.

(d) *Karl Fischer solvent*.—Mix equal vols anhyd. MeOH and CHCl<sub>3</sub>.

### 13.004 Determination

Stdze reagent, (c), by accurately weighing ca 125 mg H<sub>2</sub>O from 1 mL syringe (5 units) into 30–50 mL pretitrd solv. (Keep needle capped except while delivering H<sub>2</sub>O, to eliminate evapn.) Titr. with reagent, (c), until near end point; then add in 0.1 mL increments until end point remains 1 min (usually >50  $\mu$ amp.). Calc.  $C = \text{g H}_2\text{O}/\text{mL reagent}$ . Duplicates must agree within 0.1 mg H<sub>2</sub>O/mL reagent.

Melt sample in closed Whirl-Pak bag supported in 400 mL beaker  $\leq 2$  hr in oven at  $40 \pm 2^\circ$ . Mix thoroly by first gently squeezing bag and then stirring ca 1 min with glass rod or spatula. Remove portion with 10 mL syringe, weigh, add portion contg ca 100 mg H<sub>2</sub>O to 30–50 mL pretitrd reagent, and reweigh. Titr. as in stdzn.

$$\% \text{ H}_2\text{O} = \text{mL reagent} \times C \times 100/\text{g sample}$$

### 13.005 Ash (3)—Official Final Action

#### *AOAC-Office International du Cacao et du Chocolat Method*

Accurately weigh 2–5 g prepd sample, **13.001**, into 25–50 mL Pt, quartz, or Vycor dish previously heated to 600°, covered with watch glass, cooled in desiccator, and weighed. Carbonize by either (1) slowly bringing temp. of furnace to 600° in hood with exhaust vent open or door not completely closed; or (2) heating under IR lamps until smoking ceases and then transferring to 600° furnace. Heat 2 hr, moisten cooled ash with alcohol, dry

under IR lamps or on steam bath, and re-ash at 1 hr intervals until change in wt is  $< 1$  mg, or overnight. Cover with watch glass, cool in desiccator, and weigh as soon as room temp. is attained.

### 13.006 Soluble and Insoluble Ash Official Final Action

Proceed as in **31.015**, using ash from **13.005**.

#### *Alkalinity of Insoluble and Soluble Ash (4) Official First Action*

#### *AOAC-Office International du Cacao et du Chocolat Method*

### 13.007 Reagents

(a) *Bromocresol green indicator soln*.—Dissolve 0.75 g indicator in 100 mL alcohol.

(b) *Citrate buffer soln*.—pH 4.50 at 20°. Dissolve 21.008 g citric acid.H<sub>2</sub>O in 200 mL 1N NaOH and dil. to 1 L with freshly boiled H<sub>2</sub>O. Mix 719 mL of this soln with 281 mL 0.1N HCl, **50.011–50.012**, and add 10 mg HgI<sub>2</sub> as preservative.

### 13.008 Determination

(a) *Insoluble ash*.—Ash sample as in **13.005**. Add 10 mL H<sub>2</sub>O to ash, heat nearly to bp, filter thru ashless paper into 300 mL erlenmeyer, and wash with hot H<sub>2</sub>O to total vol. of ca 60 mL. Cool and reserve for (b). Return paper and contents to ashing dish, burn off paper, and reignite 30 min at 600°. Cover with watch glass, cool in desiccator, and weigh as soon as room temp. is attained (insol. ash). Add 10 mL hot H<sub>2</sub>O and 10.0 mL 0.5N HCl, **50.011–50.012**, heat to incipient boiling, and cool. Transfer quant. to 300 mL erlenmeyer. Wash ashing dish with H<sub>2</sub>O to total vol. of ca 60 mL. Heat in boiling H<sub>2</sub>O bath 15 min, with repeated swirling. Cool, add 2 drops bromocresol green, (a), and titr. excess HCl with 0.1N NaOH, **50.032–50.035**, using citrate buffer soln with 2 drops bromocresol green as end point color ref. Titr. blank similarly. Express alky in terms of mL 1N alkali/100 g sample.

(b) *Soluble ash*.—Titr. reserved filtrate from (a) with 0.1N HCl, **50.011–50.012**, using Me orange, **6.004(g)**. Express alky in terms of mL 1N acid/100 g sample.

### 13.009 Ash Insoluble in Acid—Official Final Action

Proceed as in **30.008**, using total ash obtained in **13.005**, or H<sub>2</sub>O-insol. residue obtained in **13.006**.

### 13.010 pH (5)—Official Final Action

#### *Office International du Cacao et du Chocolat-AOAC Method*

(a) *For products other than cacao butter*.—Weigh 10 g sample into 150 mL beaker and slowly add, with stirring, 90 mL boiling H<sub>2</sub>O. Suspension must be free from lumps. Filter, cool filtrate to 20–25°, and immediately det. pH, using electrodes and potentiometer stdzd with buffers at pH 4.00, **50.007(c)**, and 6.86, **50.007(d)**. Report to nearest 0.1 pH unit.

(b) *For cacao butter*.—Melt sample and mech. stir 5 min with equal wt of H<sub>2</sub>O at 50°. Sep. aq. layer, cool to 20–25°, filter, and det. pH as in (a).

**13.011 Total Nitrogen—Official Final Action****AOAC-Office International du Cacao  
et du Chocolat Method**

Proceed as in 2.057, using 0.7–2.2 g sample. Small amt of paraffin or silicone antifoam may be added to reduce foaming. Digest 1–2 hr after soln is clear. Protein =  $N \times 6.25$  (includes N from purines and other N-contg compds). Report % N to nearest 0.01%; protein, 0.05%. Duplicate detns should agree within 0.30% protein.

**SHELL (6)****13.012 ★ In Cacao Nibs—Official Final Action ★**

Sample is reduced and sieved, and shell is picked out by hand. See 13.010–13.014, 12th ed.

**In Cacao Products Other Than Cacao Nibs**

(Following methods include detns the results of which can be used to est. amt of shell when compared with corresponding values obtained on authentic samples of cacao shell.)

**13.013 Crude Fiber (7)—Official Final Action**

(a) *In cacao products not containing dairy ingredients.*—Treat 7 g liquor (or amt of sweet chocolate or cocoa equiv. to 7 g liquor) in centrf. bottle with two 100 mL portions ether, centrfg and decanting after each addn. Dry residue on steam bath and then in oven at ca 100° and crush to powder in bottle with flat-end rod. If necessary, grind material in mortar and ext third time with ether. Wash mixt. in bottle with three 100 mL portions H<sub>2</sub>O at room temp., shaking well each time, until no cacao material adheres to bottle. Centrf. 10–15 min after each washing, and decant aq. layer. Wash residue in same fashion with two 100 mL portions alcohol and one 100 mL portion ether. Transfer residue to Pt dish, dry to const wt, and grind in mortar. Weigh 2 g dried material and det. % crude fiber (*D*) as in 7.065. Calc. % crude fiber on H<sub>2</sub>O-, fat-, and sugar-free basis (*E*) by formula  $E = 0.7D$ .

(b) *In cacao products containing dairy ingredients.*—Treat 50 g milk chocolate with three 100 mL portions ether in centrf. bottle, centrfg and decanting after each addn. Dry residue in bottle and crush to powder with flat-end glass rod as in (a). Shake with 100 mL 1% Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln, and let stand 30 min. Centrf. and decant. Wash in bottle with three 100 mL portions H<sub>2</sub>O at room temp., shaking well each time, until no cacao material adheres to bottle. Centrf. 10–15 min after each washing and decant. Wash residue in same fashion with two 100 mL portions alcohol and one 100 mL portion ether. Transfer residue to Pt dish, dry to const wt at 100°, and grind in mortar. Weigh 2 g dried material and det. % crude fiber as in 7.065. % Crude fiber found  $\times 0.7 =$  % crude fiber on fat-, sugar-, H<sub>2</sub>O-, and milk-free basis.

**13.014 Pectic Acid (8)—Official Final Action**

(Sweet chocolate, usually characterized by its color, may contain small amts of milk solids. When in doubt, use method for milk chocolate, (c). Caution: See 51.086.)

(a) *In sweet chocolate containing no milk solids.*—(1) *Extraction of fat.*—Weigh, within  $\pm 0.15$  g, amt (14–60 g) of well mixed grated sample contg 4.7–5.2 g dry, fat-free cacao, and place in one or two 250 mL centrf. bottles. (If sample is  $> 50$  g, distribute it ca equally between 2 bottles.) (Make detns in duplicate.) Add 120 mL pet ether (bp 30–65°), or ether, at ca 30°, to each bottle, shake thoroly, centrf., and decant. Repeat extn with another 100

mL solv.; then ext with 100 mL alcohol, decant, and discard exts.

(2) *Extraction of color, tannins, etc.*—To each bottle add (from graduate) 150 mL acidified 82% alcohol (10 mL HCl + 432 mL alcohol dild to 500 mL with H<sub>2</sub>O) that has been warmed so that temp. of liq. in centrf. bottle is 55°. Stopper, shake vigorously 2 min, centrf. 6–8 min, decant, and discard supernate. Add 100 mL alcohol to residue in each bottle, shake, centrf. as before, decant, and discard exts.

(3) *Extraction of pectin.*—Measure 150 mL H<sub>2</sub>O in graduate, add ca 75 mL to 1 bottle, stopper, shake vigorously to disperse residue thoroly, decant into other bottle contg remainder of sample, and again shake vigorously until residue is thoroly dispersed. Decant mixt. into 500 mL wide-mouth erlenmeyer, rinse mouth of bottle with ca 1 mL H<sub>2</sub>O from wash bottle, and complete transfer of residue from bottles with ca 45 and 30 mL successive portions of H<sub>2</sub>O remaining in graduate. Make mixt. in flask just alk. to litmus with NH<sub>4</sub>OH (1+1) (ca 0.7 mL; note vol. used; See Note). Acidify with HOAc, add 0.5 mL excess, and then add 50 mL 2% (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub>·H<sub>2</sub>O soln, using soln to wash down sides of flask.

Pass glass stirrer, with 2.5–3 cm (1–1¼") diam. loop (perpendicular to shaft on end), loosely thru hole in rubber stopper or thru glass tube of slightly larger diam. held in rubber stopper placed in mouth of flask. Attach shaft of stirrer to motor, or air rotor, to stir contents of flask continuously, immerse flask below level of contents in H<sub>2</sub>O bath held at 90–92°, and stir moderately 3 hr. If level of liq. in flask is appreciably reduced, add enough hot H<sub>2</sub>O to bring back to original level.

Remove flask, cool to 45°, quant. transfer contents to 250 mL vol. flask, dil. to vol. with H<sub>2</sub>O at 45°, and add 1.5 mL excess to correct for vol. of cacao solids. Mix contents well, pour into centrf. bottle, and centrf. at 1800 rpm ca 15 min. Decant supernate ext, which may be turbid or opalescent, into 400 mL beaker. Rinse any residue in flask into centrf. bottle with alcohol and reserve this cacao residue for further treatment to est. fat-free cacao in the sample. Warm ext to 45°, pour into graduate, note vol., and return to beaker. Rinse graduate with two 5 mL portions H<sub>2</sub>O, and add to beaker. Cool in bath to 15–17°, make alk. to phthln (internal indicator) with 15% NaOH soln, and add 11 mL excess. (See Note.) Stir, and let stand in bath 20 min at 15–17°. Decant alk. liq. into two 250 mL centrf. bottles, distributing vol. ca equally. Let drain, and rinse twice with 5–8 mL cold H<sub>2</sub>O, adding 1 rinsing to each bottle. Add 10 mL HCl to each bottle, with stirring, and then gradually add, with continued stirring, 40 mL alcohol. Add to each bottle 0.8–1.0 g mixt. of Filter-Cel and Celite 545 (1+1). Stir, rinse rod, stopper bottles, shake well, and centrf. 10–12 min. Decant and discard supernates without disturbing sediment, and wash residues once by shaking contents of each bottle with 100 mL alcohol, centrfg, and decanting.

Add 75 mL H<sub>2</sub>O to 1 bottle, stopper, and shake well. Make slightly alk. with few drops NH<sub>4</sub>OH (1+1) and shake again. Decant liq. into second bottle, stopper, shake again, make alk. to litmus with NH<sub>4</sub>OH (1+1), and add 0.5 mL excess. Stopper, and shake thoroly 1–1.5 min to dissolve pectic acid ppt. (Drops of liq. clinging to lip of bottle may be washed into second bottle with small squirt of H<sub>2</sub>O from wash bottle; otherwise do not rinse at this point.) Filter, with suction, thru hardened paper (Whatman 41-H or 54, or equiv.) on 11 cm buchner. Let bottle drain well; then rinse bottle twice with 25 mL portions H<sub>2</sub>O, each contg 1–2 drops NH<sub>4</sub>OH (1+1), pour rinsings on filter, and wait for each rinse to drain thru filter before adding another.

Pour filtrate into 250 mL centrf. bottle, let flask drain, and rinse twice with 5 mL H<sub>2</sub>O. (Use of bell jar permits filtration directly into centrf. bottle.) Add 5 mL HCl to contents of centrf. bottle, stir in 90–100 mL alcohol, rinse rod with alcohol (do not add

★ Surplus method—see inside front cover.

filter-aid), stopper, shake, and centr. 8 min at 1500–1800 rpm. Decant into beaker, retaining most of ppt in bottle, and filter liq. thru 15 cm Whatman 41-H paper, or equiv., on fluted funnel. Pour ppt and liq. remaining in centr. bottle onto filter paper and drain thoroly. (Do not rinse.)

Quant. transfer ppt in bottle and on filter to 250 mL beaker, using total of 75 mL 60–75° H<sub>2</sub>O. Cool beaker and contents in bath at 15–17° and add, with stirring, 15% NaOH soln (also cooled) until mixt. is alk. to phthln (internal indicator). Add 3 mL excess and let stand in bath 15 min at 15–17°. During this time, heat on steam bath 2 wash bottles, contg, resp., wash solns: *A*, mixt. of 200 mL H<sub>2</sub>O, 50 mL alcohol, and 20 mL HCl (1+2.5); *B*, 400 mL alcohol dild to 950 mL with H<sub>2</sub>O.

Remove beaker from bath, acidify contents with 10 mL HCl (1+2.5) while stirring, and dil. to 100 mL with H<sub>2</sub>O. (Est. vol. by comparison with 100 mL in similar beaker.) Add few glass beads, cover, bring contents to bp, and boil 5 min. Remove from heat; add 10 mL HCl, with stirring, and then 400 mg *prepd asbestos* (previously alkali- and acid-washed and ignited, and free of coarse particles). Stir 40 sec, and immediately filter thru Whatman 41-H paper, or equiv., on 7–11 cm buchner with very gentle suction. (Suction should be so gentle that it can hardly be felt when thumb is placed on rubber tube before attaching tube to flask; sample should filter in small steady stream, and filtrate should be clear or only slightly opalescent, with no immediate sepn of ppt.) Wash beaker and filter with three ca 25 mL portions wash soln *A*, and then with four or five ca 25 mL portions wash soln *B* to remove acid. (Washings should be clear and pass thru filter readily. Ignore any appearance of ppt in flask at this stage.)

Place filter and ppt on fairly large, short-stem funnel, and wash pectic acid ppt and asbestos into Pt dish with hot H<sub>2</sub>O. Det. blank on 400 mg asbestos by adding it to hot acid soln, filtering, and drying in same manner as sample. Heat dishes on steam bath until asbestos and ppt appear thoroly dry. Dry sample and blank in oven at 100° to const wt ( $\pm 0.2$  mg; ca 1 hr), cool in desiccator, weigh, ignite, cool, and reweigh. Loss in wt of sample – loss in wt of blank = wt of pectic acid in aliquot taken.

This wt  $\times$  250/vol. ext taken = wt pectic acid in sample.

To obtain dry, fat-free cacao in sample, add 100 mL alcohol to cacao residue reserved in centr. bottle, stopper, shake well, centr., and decant. Again shake with 100 mL alcohol, rinse stopper, and wash down sides of bottle with alcohol from wash bottle; centr. and decant. Repeat extn, using 100 mL ether, washing down sides, centr., and decanting. Let residual ether evap. Using brush and spatula, quant. transfer residue to tared Al dish with cover; dry dish and contents 1–2 hr in oven at 100°; cover dish, cool in desiccator, and weigh. Wt residue  $\times$  1.9 = wt dry, fat-free cacao in sample.

Wt pectic acid  $\times$  100/wt dry, fat-free cacao = % pectic acid.

(b) *In chocolate liquor, breakfast cocoa, cocoa, and low-fat cocoa.*—Place ca 15 g cocoa or 25 g chocolate liquor, *prepd* as in 13.001, in centr. bottle. To remove most of fat, shake thoroly with 100 mL pet ether (bp 30–65°) or ether; centr., decant, and repeat extn with another 100 mL pet ether or ether. Shake residue with third portion solv., and filter thru Whatman 41-H or 54 paper, or equiv., on 11 cm buchner with gentle to moderate suction. (Apply vac. and wet filter with solv. before starting filtration.) Let residue suck dry, transfer to porcelain dish or casserole, grind gently with pestle to pulverize and mix, and transfer to Al dish with cover. Dry ca 45 min in oven at 100°, cover dish, and cool in desiccator. Weigh 5 g of the dry, fat-free residue into 250 mL centr. bottle, and proceed as in (a)(1), last sentence, beginning "... then ext with 100 mL alcohol, ..." and

continue as in (2) and (3) thru next-to-last par. (directions for calcg wt pectic acid in sample).

(Wt pectic acid found/5)  $\times$  100

= % pectic acid in dry, fat-free cacao.

(No estn of dry, fat-free cacao is necessary, since weighed amt of dry, fat-free cacao is used for pectic acid detn.)

(c) *In products containing milk solids.*—(1) *Removal of fat.*—Weigh ( $\pm 0.2$  g) sample contg ca 5 g dry, fat-free liquor (60–110 g milk chocolate, etc.), and distribute ca equally between two 250 mL centr. bottles. Add 120 mL pet ether or ether at 25–30°, shake thoroly, centr., and decant. Add another 120 mL portion tepid solv. to each bottle, shake thoroly, centr., and decant. In same manner ext contents of each bottle with 100–110 mL acetone.

(2) *Extraction of milk protein.*—Add enough acetone (ca 90 mL) to make total of ca 110 mL with acetone remaining in residue. (Est. on basis that  $\frac{1}{2}$  original sample of 75 g retains ca 20 mL acetone in residue of each bottle.) Stopper, and shake vigorously to disperse residue thoroly. Quickly add 100 mL *triethanolamine soln* (90 mL triethanolamine dild to 500 mL with H<sub>2</sub>O) to each bottle, stopper immediately, and shake well 2 min. Let stand ca 1 min for foam to rise; then centr. 12–14 min at 1500–1800 rpm. Carefully decant and discard supernate without disturbing residue, and ext residue with 100–120 mL mixt. of acetone and the triethanolamine soln (110+100), centrfg and decanting as before. Then add 100 mL 85% alcohol to each bottle, shake, centr., decant, and discard ext.

To residue in each bottle add 15–20 mL acidified 82% alcohol, (a)(2), stir, and add enough HCl to make residue acid to litmus. Continue as for sweet chocolate, beginning with (a)(2).

*Note:* Vol. of NH<sub>4</sub>OH used should be noted, excess avoided, and approx. concn of NH<sub>3</sub> detd. (Soln becomes much less concd on standing from loss of NH<sub>3</sub> around stopper.) This is necessary because in first hydrolysis (saponification) of pectin, part of NaOH soln added (after soln of sample has been made alk. to phthln) is used up in replacing with Na the NH<sub>4</sub> in NH<sub>4</sub> salts present. The 11 mL 15% NaOH soln added furnishes excess of 4–5 mL of this soln over amt required to neutze acid and replace NH<sub>4</sub> with Na, provided  $\leq 1.15$  mL 7.5N NH<sub>4</sub>OH (= 2.3 mL 15% NaOH soln) is added to neutze residual HCl. (Approx. 3.75 mL 15% NaOH soln is needed to replace with Na the NH<sub>4</sub> in (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln used in extn of pectin.) If  $> 1.15$  mL of the NH<sub>4</sub>OH soln is needed to neutze HCl in (a)(3), correspondingly increase vol. of 15% NaOH soln used for saponification, but avoid excess of  $> 5$ –6 mL.

### Spiral Vessel Count (9)—Official Final Action

#### 13.015

#### Apparatus

(a) *Sieve.*—No. 230, 5" (13 cm) diam., stainless steel.

(b) *Grinding equipment.*—(1) *Coarse grinding (cutting action).*—Labconco mill No. 900 (discontinued), Hobart Food Cutter No. 84181-D (Hobart Manufacturing Co., Troy, OH 45374), or equiv. (2) *Fine grinding.*—13 cm (5") glass mortar and pestle or Torsion Balance Co. elec. mortar grinders MG1 or MG2 (Torsion Balance Co., 35 Monhegan St, Clifton, NJ 07013). Adjust MG2 so that pestle and shaft are not under tension by loosening top knob and lock nut by 3 turns and adjust closing spring control to  $\frac{1}{2}$  tension.

(c) *Aluminum dish.*—Diam. ca 77 mm, ht ca 33 mm; with cover.

(d) *Brush.*—No 10, nylon, rubber set, oval sash paint brush with bristles cut to 4–4.5 cm (available from Sherwin-Williams Co., Prospect Ave, Cleveland, OH 44101, or distributors).

#### 13.016

#### Preparation of Sample

(a) *Chocolate liquor, chocolate.*—Prep. as in 13.001(b).

(b) *Expeller cake.*—Crush with mortar and pestle and grind

to pass No. 30 sieve in mill, (b)(1), ca ½ teaspoonful at time. Mix well and store in tightly stoppered jar.

(c) *Cocoa press cake*.—Prep. and store as in (b). (Many samples can be easily pulverized after drying 2–3 hr at 60–70°.)

(d) *Cocoa*.—Use as is. Store as in (b).

### 13.017

#### Defatting and Grinding

(Caution: See 51.054.)

Set up in hood No. 230, 5" (12.7 cm) sieve in 15 cm (6") glass funnel with tip dipping ca 2 cm into 500 mL flat-bottom Pyrex centr. bottle.

Place 15 g cocoa, coarsely ground (30–40 mesh) cocoa press cake, or expeller cake, or 25–30 g chocolate or chocolate liquor in 250 mL centr. bottle. Add 100 mL ether, stopper, shake thoroly to dissolve fat, and pour onto sieve. Wash material on sieve well with ether. Wash lower rim and both sides of sieve and inside of funnel with ether. Let material on sieve stand until dry (ca 15 min).

Centrf. mixt. in 500 mL centr. bottle 10 min at 2000 rpm. Decant and discard supernate. Replace centr. bottle under funnel.

Place sieve with dried cocoa material in receiver (sieve bottom pan). Brush material thru sieve with No. 10 sash paint brush. Transfer retains, using brush, to 12.7 cm glass mortar and grind ca 45 sec with glass pestle, or grind 2 min in motor-driven mortar grinder. Transfer to sieve and rebrush. Repeat grindings and brushings until virtually all material passes thru sieve. Quant. transfer material, including small amt on sieve (<20 mg), thru funnel to the 500 mL centr. bottle. Clean with brush, and clean brush against rim of sieve. Wash screen, receiver, mortar and pestle, and funnel (but not brush) with ether, letting washings run into centr. bottle. Rub off coated material on funnel and other app. with policeman, rinsing with ether thru funnel into centr. bottle. Stopper bottle and shake thoroly. Remove stopper and rinse with ether. Centrf. 10 min at 2000 rpm. Decant and discard supernate. Add 100 mL ether and repeat extn. Add 100 mL ether, stopper, and shake. Immediately pour into fritted glass crucible (disk diam. 60 mm; medium porosity) under vac. Wash material from bottle into crucible with ether. Wash twice with ca 35 mL ether and continue vac. until dry (ca 20 min).

Quant. transfer material from crucible to glass mortar and grind gently until fine. (Spoon may be used in transfer but use rubber policeman to scrape disk.) Quant. transfer ground material to Al dish. With cover in place, rotate dish until contents are well mixed. Dry on steam bath 10–15 min to remove traces of ether, and then in oven 1 hr at 100°.

### 13.018

#### Determination

Make duplicate detns. Accurately weigh 0.350 g extd and dried material and transfer to 150 mL beaker. Gradually stir in 25 mL 4% NaOH soln until smooth. Bring to initial boil, using asbestos mat over flame. Immediately reduce to weak flame and boil gently 2 min with frequent stirring. Cool somewhat and transfer to 25 × 100 mm Pyrex culture tube with small portions H<sub>2</sub>O. Centrf. until clear (3 min) at full speed of International Clinical Centrifuge, using No. 571 curved rubber cushion in No. 320 shield, or equiv. Decant carefully and discard supernate. Add H<sub>2</sub>O to tube until ca ¾ full, stopper, and shake until residue is well dispersed. Centrf. and decant as before.

Add H<sub>2</sub>O to tube until ca ½ full, stopper, and shake until product is well dispersed. Transfer soln to 50 mL g-s graduate contg 25 mL glycerol. Wash remaining material from tube to graduate with small portions H<sub>2</sub>O, stoppering and shaking tube to aid transfer. Stopper graduate, shake, dil. to 50 mL with H<sub>2</sub>O, and shake. Transfer to 100 mL beaker. Stir well with vertical

rotary motion. While stirring, withdraw small drop to Howard mold counting chamber, and make slide as in 44.096. Fisher Scientific Co. Scoopula (Cat. No. 14–357) bent at right angles ca 2 cm from broad end is useful for stirring; metal prong strip of Acco paper fastener ca 6 mm wide bent ca 135°, 6 mm from end, is useful for withdrawing drop.

With microscope adjusted for mold counting (field of view 1.382 mm at 100×), count fields pos. for spiral vessels, at varying depths, at 200× in 25 fields of each of 8 slides of each of the 2 detns (total of 400 fields). Report as pos. field one that contains any portion of section of spiral vessels, but none smaller than well developed "S" or "Z" either sep. or attached to piece of shell. (See 13.020.) Average results and report as % pos. fields present. This is spiral vessel count.

Det. % shell in chocolate component by comparison with std curve prepd from spiral vessel count values listed in Table 13.01 plotted against % shell in chocolate component. Use column for counts listed under "≤15% shell."

Table 13.01. Standard Spiral Vessel Count Values

% Shell in Chocolate component	Spiral Vessel Counts	
	≤ 15% Shell (0.350 g/50 mL)	>15% Shell (0.200 g/100 mL)
0	4.5	1.5
1	15	5.8
2	24.4	9.7
3	32.8	13.2
4	40	16.6
5	47	19.7
8	62.2	27.7
11	72.9	34.8
15	83.4	42.4
20	91.1	50.1
30	98.2	62.1
60		80.0
100		86.8

### 13.019

#### Spiral Vessel Count Values

For 1–15% shell (spiral vessel counts of 15–83.4), following formula gives values comparable to Table 13.01:

$$S = (538P - 1777)/(7043 - 50P),$$

where  $S$  = shell in chocolate component and  $P$  = spiral vessel count.

For samples contg >15% shell (spiral vessel count >83.4) repeat detn thruout, but weigh 0.200 g sample and dil. to 100 mL with H<sub>2</sub>O in 100 mL g-s graduate contg 50 mL glycerol. Count at 200×. Use column for counts listed under ">15% shell" for prep std curve.

### 13.020

#### Counting Instructions

Spiral vessels vary greatly in size. No distinction is made in counting because of size differentiation. In appearance spiral vessels have parallel walls of even intensity with clear centers. On occasional piece, walls may be frayed due to grinding. Walls of very small vessels do not appear as sharp as those of the larger ones at 200×. Some spirals are closely knit together. Photomicrographs of spiral vessels and pos. sections of them are shown in Fig. 13.01.

In counting spiral vessels, most pos. fields counted will have easily recognized pos. spiral vessel figures such as long or short mass of spiral vessels, large broken sections of these, or sometimes tangled mass of spiral vessels. Some sine wave-like figures and some full "S"- or "Z"-like figures will be found.

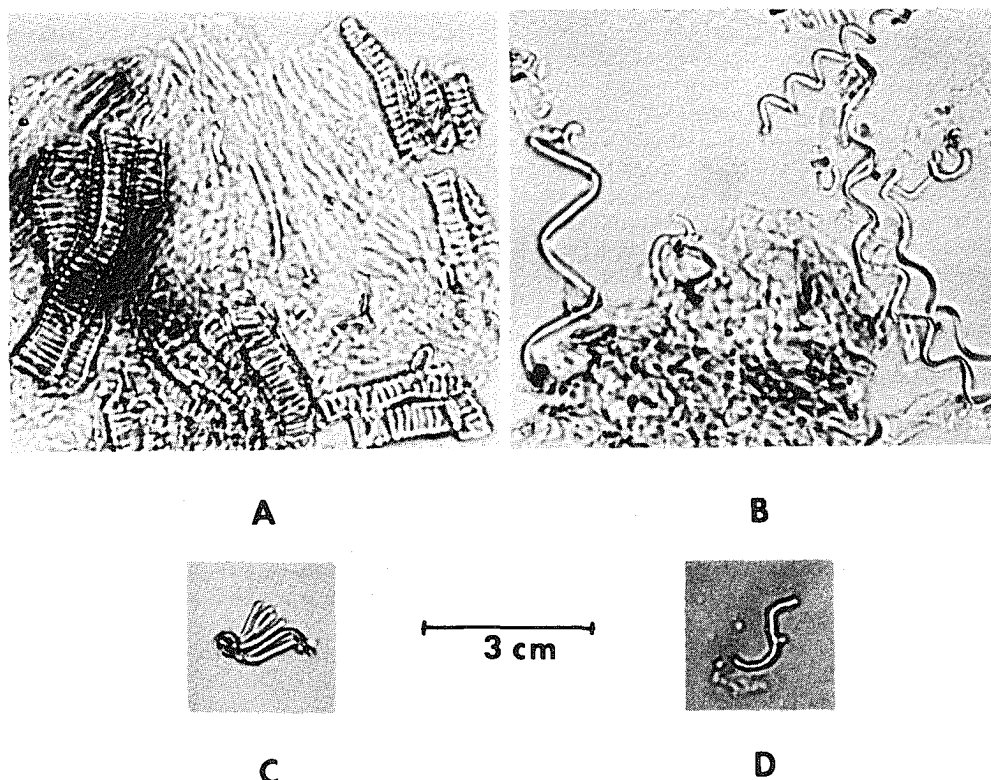

FIG. 13:01—Spiral vessel sections ca 340 $\times$ . A, Mass of spiral vessels; note size differential and narrowing effects. B, Spiral vessels stretched out; note difference in size. C, Broken section; count pos. if three joined rods are present. D, Pos. "S"-shaped section.

There will, however, be some smaller figures and some poorly formed "S"- or "Z"-like figures present in some fields. For these figures, the following applies:

"S"- or "Z"-like figures or mirror images of these should have  $\frac{1}{3}$  or more of top and bottom normal linear distance for such figure and not just stubs. One-third of center section is est. of this distance. If "2"-like figure is found, lower portion or "V" part of figure should be well extended and sufficient top curve should be present so that figure does not appear essentially like a "V." Figures may be stretched out. Spiral vessels in breaking sometimes break so that there will be joined sections of half circles or less. Count as pos. any such section consisting of  $\geq 3$  nearly  $\frac{1}{2}$  circles joined. Two spiral circles joined together are counted pos. Circles showing no spiraling are not counted. A "W" figure is pos.; a "V" or "C" is not. In viewing small section of spirals perpendicular to axis, 2nd and 3rd spiral, etc., may be just faintly seen, but the section should be counted as pos.

There is some fine cell wall structure present which when broken may fracture into "Z"-like characters similar in appearance to "Z" formed from small thin spiral vessels. Care should be exercised in discriminating between the two.

#### Stone Cell and Group Count Method (10) Official Final Action

##### 13.021

##### Apparatus and Reagents

(a) *Slide and cover glass*.—75  $\times$  38 mm slide with lines 0.5 mm apart, nearly across slide, parallel to 75 mm side, and ruled from top to bottom; 33  $\times$  33  $\times$  0.2 mm cover glass.

(b) *Scoop*.—Thin (ca 0.01–0.02 mm thick) stainless steel strip ca 4.8 mm wide with 90° bend extending outward 3 mm.

(c) *Magnetic stirrer*.—With stirring bar ca 16 mm long  $\times$  6 mm diam. Stirring bar 13  $\times$  8 mm with ridge in center will circle

walls of 1 oz ointment jar (ca 36 mm diam  $\times$  40 mm high internal measurements) with distinct convex bottom, giving both vortex mixing and stirring.

(d) *Bellucci's reagent*.—HOAc-H<sub>2</sub>O-HNO<sub>3</sub> (36 + 9 + 5).

##### 13.022

##### Defatting and Grinding

See 13.017.

##### 13.023

##### Determination

Mix dried (1 hr at 100°) product by tumbling in covered dish. Make duplicate detns. Accurately weigh 0.500 g extd and dried material and transfer to 150 mL beaker. Gradually stir in 20 mL portion Bellucci's reagent until smooth; rinse walls of beaker and stirring rod with remainder. Stir gently. Fill short-neck, 100 mL, r-b flask with cold H<sub>2</sub>O to neck and place on top of beaker; let rod rest in spout of beaker. Bring soln to initial boil, using asbestos mat over small flame. Immediately reduce to very weak flame and boil gently 10 min with frequent gentle swirling, keeping beaker and flask together. Cool ca 5 min.

Accurately weigh 25  $\times$  100 mm Pyrex, rimless culture tube in 30 mL beaker (holder). Quant. transfer sample to culture tube with small portions H<sub>2</sub>O, scrubbing beaker and rod with rubber policeman. Centrf.  $\geq 3$  min at full speed in International Clinical centrf., using IEC No. 571 curved rubber cushion in IEC No. 320 shield, or equiv. Decant carefully and discard supernate (some flocculent material may be present). Add H<sub>2</sub>O to tube to ca  $\frac{3}{4}$  full, stopper, and shake until residue is well dispersed. Remove stopper, rinse, centrf., and decant as before.

Add aq. glycerol (3+2) to culture tube until tube and holder weigh 20  $\pm$  0.03 g more than original wt. Stopper, shake vigorously until well mixed, and transfer immediately to 1 oz ointment jar contg small mag. bar. Stopper jar and let stand until bubbles disappear (ca 5–10 min).

Accurately weigh together ruled glass slide and cover glass. Stir liq. in jar 1 min on mag. stirrer at max. speed at which small bubbles do not form. Stop. In rapid sequence, push jar (to put mag. bar next to wall of jar) and, using scoop, immediately transfer drop liq. (ca  $0.04 \pm 0.01$  g) to center of tared slide, rulings up. Tap slide gently with scoop several times to remove as much liq. as possible. Place cover slip so that one edge rests just above and parallel to lower edge of slide. Lower cover slip carefully until it touches liq. and then let it drop. Liq. will ooze to edges. Do not press cover slip. Weigh prep'd slide to 0.1 mg. Place rubber stopper in jar to prevent evapn.

Place slide on comp'd microscope with or without upper half of condenser and with transmitted day-light-type filtered and diffused light. Count 2 slides from each of 2 detns as in (a) or (b):

(a) *Stone cell count*.—For cocoa, cocoa press cake, chocolate liquor, and expeller cake. Scan slide at  $100\times$  and count stone cells at  $\geq 200\times$ . Count whole stone cells, both single and in groups, and all broken stone cells which are  $\geq 0.5$  cell. Do not count smaller fragments.

(b) *Stone cell group count*.—For other chocolate products. Proceed as in (a), counting only stone cell groups contg  $\geq 2$  stone cells.

#### 13.024

#### Description of Stone Cells

Stone cells vary considerably in size, shape, and general appearance. Some are very distinct and others are relatively

indistinct. Their size varies from ca 10 to  $38\ \mu\text{m}$ ; the longest are very slender. Some very coarse stone cells up to ca  $40\ \mu\text{m}$  with thick, beaded-appearing outside wall ca  $7\ \mu\text{m}$  wide are occasionally found. Stone shapes are polygonal, generally irregular, and may contain curved areas. On well developed stone cells outside walls are  $2\text{--}3.5\ \mu\text{m}$  wide. On less distinct stone cells, outside walls are narrower and thinner; such cells are immature or not fully developed. Several near-parallel thin walls or lines, viewed microscopically, are easily visible in many stone cells. They are generally more distinct in those where outside wall is thin. See Fig. 13:02 for photomicrographs of stone cells. Stone cells usually are in group formation, consisting of  $\geq 2$  stone cells.

#### 13.025

#### Calculations

For either method, average four  $S$  values from one of formulas below and report as % shell in chocolate component:

(a) *Stone cell count*.— $S_1 = 84C/(17200M - C)$

(b) *Stone cell group count*.— $S_2 = 84G/(1700M - G)$ ,

where  $W$  = g sample;  $L$  = g dild sample;  $D$  = g of drop counted;  $C$  = stone cell count of drop;  $M$  = mg dry, fat-free sample in drop counted ( $= 1000 WD/L$ );  $S$  = % shell in chocolate component;  $G$  = stone cell groups in drop; and 9340 = number stone cells in 1 mg dry, fat-free, 250 mesh shell.

(Example: for 0.5 g sample dild to 20 g,  $S_1 = 84C/(430000D - C)$  and  $S_2 = 84G/(42500D - G)$ .)

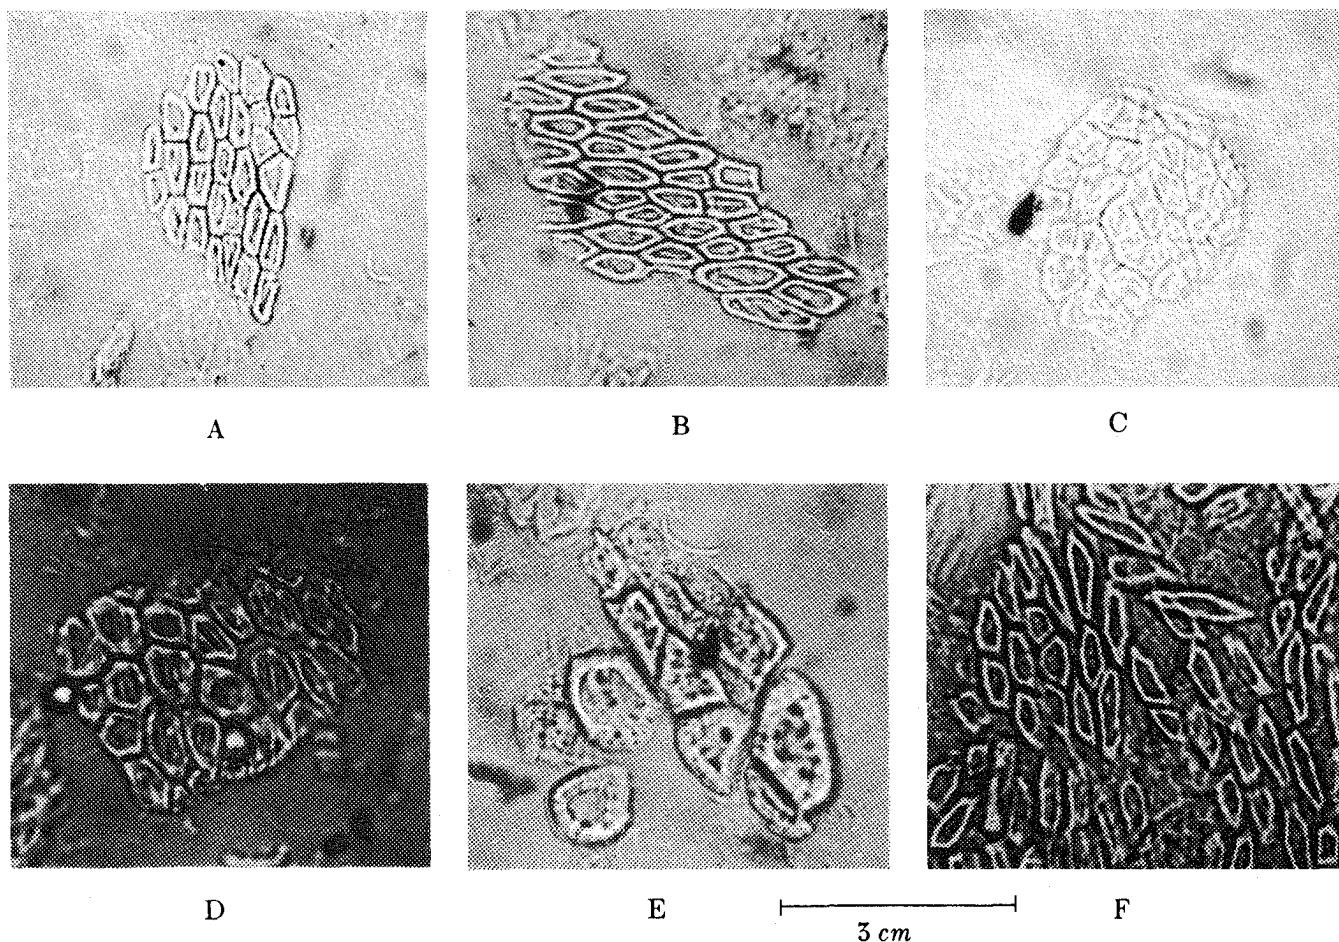

FIG. 13:02—Stone cells ca  $330\times$ : A and B, distinct stone cells; C, indistinct stone cells; D, stone cells showing distinct parallel lines in central area; E, very large stone cells infrequently found; F, long stone cells attached to a large piece of shell, showing separations between stone cells on shell

**13.026 Ash Insoluble in Acid—Official Final Action**

See 13.009.

**CACAO PRODUCTS PROCESSED WITH ALKALIES****13.027 Ash—Official Final Action**

See 13.005.

**13.028 Soluble and Insoluble Ash—Official Final Action**

See 13.006.

**13.029 Alkalinity of Insoluble and Soluble Ash  
Official First Action**

See 13.007–13.008.

**13.030 CHOCOLATE LIQUOR (11)  
OFFICIAL FINAL ACTION**

(Caution: See 51.011, 51.039, and 51.054.)

Ext 25–50 g sample (50 g if light color, indicating low liquor) as in 13.013, except in first aq. extn use 200 mL H<sub>2</sub>O for products referred to in (a) and 200 mL 1% Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln for products referred to in (b). Follow method thru aq., alcohol, and ether extns only.

With aid of small portions ether (45, 20, 15 mL, etc.) transfer residue resulting from ether, alcohol, and aq. extns to tared Al dish provided with tight-fit cover. Use small amt of acetone and policeman to transfer any material that sticks to bottle. Evap. liq. carefully on steam bath or hot plate, and dry residue in oven at 100°. Cover dish, cool in desiccator, and weigh.

To obtain wt dry, fat-free cacao mass, multiply wt residue by factor 1.43. To obtain wt chocolate liquor, multiply wt dry, fat-free cacao mass by factor 2.2. (This factor is based on fat content of 54% in chocolate liquors.)

**FAT**

(Caution: See 51.011, 51.039, and 51.073.)

**13.031 Method I (12)—Official Final Action**

(Not applicable to cacao products contg milk ingredients or to products prepd by cooking with sugar and water, and drying; cacao nibs must be finely ground. All pet ether used in this detn must be redistd at <60°.)

Prep. in Knorr extn tube, 17.021(d), first par., 6 mm tightly packed mat of asbestos, purified as for detn of crude fiber, 7.062(c), and carefully freed from coarse pieces. (Allihn type filter tube with coarse fritted disk such as Ace Glass Inc. No. 7195 is also satisfactory.) Wash filter with alcohol, ether, and little pet ether. Weigh 2–3 g prepd sample, 13.001, into tube and insert tube into rubber stopper in filtering bell jar connected to suction thru 2-way stopcock, taking care that no rubber particles adhere to tip of stem. Place weighed 200 mL erlenmeyer at such ht that tube stem passes thru neck into flask. (Lengthen stem of tube if necessary.) Fill tube to ca ¾ capacity with pet ether, and stir sample thoroly with flat-end rod, crushing all lumps. Let stand 1 min and drain by suction. Regulate suction so that collected solv. will not boil violently. Release vac. after each draining before adding more solv. Add solv. from wash bottle while turning tube between thumb and finger so that sides of tube are washed down by each addn. Repeat extns, with stirring, until fat is removed (usually 10 extns). Remove tube with stopper from bell jar, wash traces of fat from end of stem with pet ether, evap. solv., and dry to const wt at 100°.

**Method II (13)—Official Final Action  
(Office International du Cacao  
et du Chocolat—AOAC Method)**

(Applicable to cacao products with or without milk ingredients or to products prepd by cooking with sugar and H<sub>2</sub>O, and drying)

**13.032****Apparatus and Reagents**

(a) *Soxhlet apparatus*.—With 3 joints, siphon capacity ca 100 mL (33 × 80 mm thimble), 250 mL erlenmeyer, and regulated heating mantle.

(b) *Petroleum ether*.—Distd in glass, bp 30–60°.

**13.033****Determination**

Prep. sample as in 13.001(b)(1). Accurately weigh 3–4 g chocolate liquor, 4–5 g cocoas, 4–5 g sweet chocolate, or 9–10 g milk chocolate into 300–500 mL beaker. Add slowly, while stirring, 45 mL boiling H<sub>2</sub>O to give homogeneous suspension. Add 55 mL ca 8N HCl (2+1) and few defatted SiC chips or other antibumping agent, and stir. Cover with watch glass, bring slowly to boil, and boil gently 15 min. Rinse watch glass with 100 mL H<sub>2</sub>O. Filter digest thru 15 cm S&S 589 medium fluted paper, or equiv., rinsing beaker 3 times with H<sub>2</sub>O. Continue washing until last portion of filtrate is Cl-free as detd by addn of 0.1N AgNO<sub>3</sub>. Transfer wet paper and sample to defatted extn thimble and dry 6–18 hr in small beaker at 100°. Place glass wool plug over paper.

Add few defatted antibumping chips to 250 mL erlenmeyer and dry 1 hr at 100°. Cool to room temp. in desiccator and weigh. Place thimble contg dried sample in soxhlet, supporting it with spiral or glass beads. Rinse digestion beaker, drying beaker, and watch glass with three 50 mL portions pet ether, and add washings to thimble. Reflux digested sample 4 hr, adjusting heat so that extractor siphons ≥30 times. Remove flask, and evap. solv. on steam bath. Dry flask at 100–101° to const wt (1.5–2 hr). Cool in desiccator to room temp. and weigh. Const wt is attained when successive 1 hr drying periods show addnl loss of <0.05% fat. % Fat = g fat × 100/g sample. Duplicate detns should agree within 0.1% fat.

**13.034 Separation and Preparation of Fat  
for Determination of Constants—Procedure**

(Caution: See 51.011, 51.039, and 51.054.)

(a) *Not applicable to cacao products containing milk ingredients or to products prepared by cooking with sugar and H<sub>2</sub>O, and drying*.—Sep. fat from 10–40 g sample (depending upon fat content) by shaking with two or three 100 mL portions ether. Centrf. and decant. Combine exts in beaker and evap. most of ether on steam bath. Filter ether exts thru dry, folded paper and dry at 100°.

(b) *Applicable to cacao products containing milk ingredients or to products prepared by cooking with sugar and H<sub>2</sub>O, and drying*.—Proceed as in 13.033, using 20 g sample in case of milk chocolate and combining fat obtained in duplicate detns for examination.

**13.035 Iodine Absorption Number—Official Final Action**

See 28.019 or 28.021.

**13.036 Melting Point—Official Final Action**

Proceed as in 28.011. Keep fat ≥24 hr in cool place before making detn.

**13.037 Index of Refraction—Official Final Action**

**13.038 Reichert-Meissl and Polenske Values (14)  
Official Final Action**

See 28.037.

**13.039 ★ Milk Fat in Milk Chocolate ★  
Official Final Action**

Calcn. from Reichert-Meissl value. See 13.042, 12th ed.

**Unsaponifiable Matter in Cocoa Butter (15)  
Official First Action**

(If unsaponifiable matter is to be used for examination of sterols, use ethyl ether extn method, 28.081. *Caution:* See 51.039 and 51.073.)

**13.040 Determination**

(All ⚗ joints must be free of lubricants; clean with pet ether before starting. Use tools to handle flasks contg fat.)

Melt fat in 50–55° oven and filter. Accurately weigh ca 5 g filtered fat into 250 mL g-s flask. Add 50 mL alcohol and 10 mL KOH soln (60 g KOH dissolved in 40 mL H<sub>2</sub>O). Attach reflux condenser and heat 60 min on boiling H<sub>2</sub>O bath. Add 50 mL H<sub>2</sub>O thru top of condenser, shake, and cool to room temp. Run blank with all reagents.

Transfer soln to 250 mL separator with Teflon stopcock and stopper. Rinse condenser and flask with five 10 mL portions pet ether and add to separator. Shake vigorously 1 min, periodically releasing pressure by inverting separator and opening stopcock. Let stand until sepn is nearly complete. Drain soap soln as completely as possible into second 250 mL separator (do not include any pet ether). (If emulsion forms, add few mL alcohol.) Repeat extn twice with two 50 mL portions pet ether, and combine pet ether exts. Wash combined pet ether ext 3 times with 50 mL portions dil. alcohol (1+1). Drain wash solns to ca 2 mL (do not include any pet ether); then gently rotate separator and let layers sep. 5–10 min. Drain remaining wash soln. Close stopcock when pet ether starts to pass bore of stopcock. Check last wash with phthln; if alkali is present, rewash and recheck.

Transfer pet ether into 250 mL flask thru top of separator. Rinse separator and pouring edge twice with 10 mL pet ether and add rinsings to main soln. Evap. to ca 5 mL on steam bath. Transfer quant. to 50 mL flask, previously dried ≥1 hr at 100° and cooled ≥1 hr in desiccator.

Evap. to dryness on steam bath. Add 2–3 mL *acetone* and reheat on boiling H<sub>2</sub>O bath with gentle flow of air (or N) thru flask. Dry residue 30 min in 100° oven, placing flask horizontally. Cool ≥1 hr in desiccator and weigh. Repeat drying, cooling, and weighing after each drying period, until change of wt is <1.5 mg. Discard sample if wt after third weighing varies by >1.5 mg from second.

$$\% \text{ Unsaponifiable matter} = 100 \times (\text{g residue} - \text{g blank residue}) / \text{g sample}$$

**13.042 ★ Detection of Coconut and Palm ★  
Kernel Oils in Cocoa Butter and Fat  
Extracted from Milk Chocolate (16)  
Official First Action**

Saponification and observing turbidity of fatty acids from coconut and palm kernel oils on acidification. See 13.044, 12th ed.

**13.043 ★ Silver Number for Detection of Coconut ★  
and Palm Kernel Oils (17)  
Official Final Action**

Saponification, removal of Mg soaps, and pptn of Ag soaps. Ag no. is mg Ag used/g fat. See 13.045–13.046, 12th ed.

**13.044 ★ Critical Temperature of Dissolution of Fat ★  
in Acetic Acid (18)—Official Final Action**

Turbidity temp. of HOAc soln. See 13.047–13.048, 12th ed.

**13.045 Lecithin (19)—Official First Action**

(*Caution:* See 51.011, 51.040, and 51.056.)

Weigh 5 g prepd sample, 13.001, into 200 mL vol. flask, add ca 150 mL CHCl<sub>3</sub>-absolute alcohol (1+1), and shake occasionally during day. At end of day dil. to vol. with same solv., pour into 250 mL centr. bottle, stopper, and let stand overnight. Next day centr. stoppered bottle until clear (ca 15 min at 1800 rpm). Pipet 100 mL clear liq. into 500 mL Kjeldahl flask. Place Kjeldahl flask on steam bath, remove solv. with air current and det. P<sub>2</sub>O<sub>5</sub> as in 22.044 and 22.045. P<sub>2</sub>O<sub>5</sub> × 11.19 = lecithin.

P<sub>2</sub>O<sub>5</sub> may be detd by 3.068, in which case conc. the 100 mL clear liq. in 250 mL beaker, wash into small crucible with solv., evap., and proceed as in 3.067. After digestion on steam bath, crucible must be heated cautiously on gauze until dry, and heating continued until frothing ceases and most of fat has smoked off before ashing in furnace. Ashing may be done in beaker in which ext is evapd.

**DAIRY INGREDIENT CONSTITUENTS****13.046 Milk Fat in Milk Chocolate—Official Final Action**

See 28.037 and 13.039.

**13.047 Milk Protein (20)—Official Final Action**

(Not applicable to chocolate products contg milk protein which has been subjected to high heat treatment)

Weigh 10.0 g finely divided milk chocolate into 250 mL or larger centr. bottle and ext twice with ca 100 mL ether by shaking until uniform, centrfg, and decanting ether layer each time. Place in bottle 2-hole stopper carrying bent glass tube, and straight glass tube that extends into bottle ca 1/3 of way to bottom. Expel ether by applying suction to bent tube and drawing moderate air current thru bottle while it is in moderately warm (not hot) place. When ether is expelled, pipet 100 mL H<sub>2</sub>O into bottle. Stopper, and shake vigorously 4 min. Pipet in 100 mL 1% Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln. Stopper, and shake vigorously 3 min. Let stand ca 10 min and again shake 1–2 min. Centr. ca 15 min at high speed (ca 1800 rpm).

Decant supernate into beaker. Pipet 100 mL into dry 250 mL beaker and add 1 mL HOAc while stirring gently. Let stand few min so ppt can partly sep., and add, with stirring, 4 mL 10% *tannic acid soln* (soln should be ≤1 week old). Let ppt settle few min; then filter on 7 cm buchner with moderate suction. Filtrate

★ Surplus method—see inside front cover.

should be clear. Use as filter S&S 589 white ribbon paper, or equiv., overlaid with medium layer of paper pulp, prepd by shaking one 15 cm No. 1 Whatman paper, torn to bits, with H<sub>2</sub>O. Using *wash soln* (add 1 mL HOAc and 2 mL 10% tannic acid soln to 100 mL 1% Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln), transfer all ppt to funnel with aid of policeman. Wash on filter 1 or 2 times. Loosen filter around edge with spatula. Carefully roll up and remove filter and ppt to Kjeldahl flask. Transfer to flask any particles of ppt clinging to funnel or spatula with small pieces of damp filter paper. Det. N as in 2.057.  $N \times 2 \times 6.38$  = total casein and albumin in the 10 g taken for analysis. Casein and albumin  $\times 1.07$  = total milk protein.

### 13.048 Lactose (21)—Official Final Action

(In absence of other reducing sugars)

Det. reducing sugars before inversion as in 31.038 in aliquot (usually 20 mL) of the Pb-free filtrate obtained in 13.049. Det. reduced Cu as Cu<sub>2</sub>O by volumetric thiosulfate method, 31.041. Correct for Cu<sub>2</sub>O due to sucrose as follows: Obtain approx. % lactose, using data obtained in 13.049, as follows:

$$\text{Approx. lactose} = [P(1.1 + X/100) - S]/0.79.$$

From calcd polarimetric sucrose/lactose ratio and total Cu<sub>2</sub>O obtained as above, det. amt of Cu<sub>2</sub>O to be subtracted from total Cu<sub>2</sub>O found, using graph, Fig. 13.03. Convert corrected Cu<sub>2</sub>O to g lactose (L), using table, 52.019. Then obtain % lactose from following relationship:

$$\% \text{ lactose} = L(110 + X)/0.26C,$$

where X = value obtained in polarimetric sucrose detn and C = vol. soln (mL) used in above lactose detn.

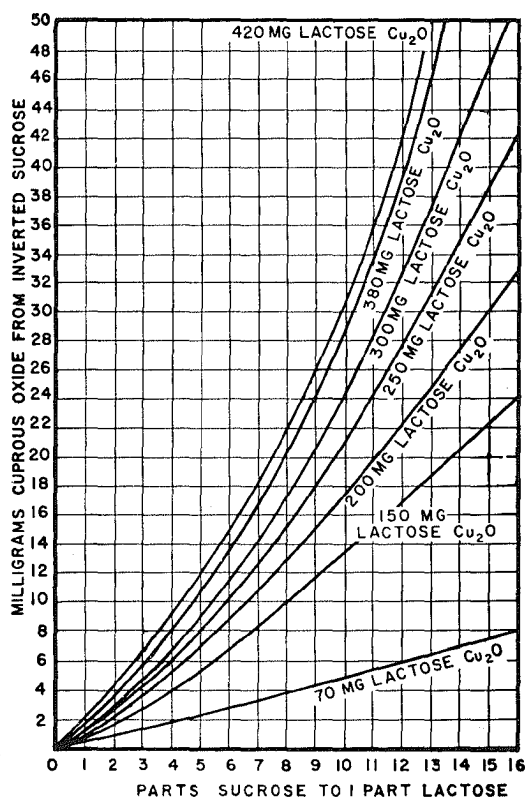

FIG. 13.03—Graph used in correcting cuprous oxide for effect of sucrose

## SACCHARINE INGREDIENTS OTHER THAN LACTOSE

### 13.049 Sucrose (21)—Official Final Action

Transfer 26 g prepd sample, 13.001, to 250 mL centr. bottle, add ca 100 mL pet ether, shake 5 min, and centr. Decant clear solv. carefully and repeat extn with pet ether. Place bottle contg defatted residue in warm place until pet ether is expelled. Add 100 mL H<sub>2</sub>O and shake until most of chocolate is detached from sides and bottom of bottle. Loosen stopper and carefully immerse bottle 15 min in H<sub>2</sub>O bath kept at 85–90°, shaking occasionally to remove all chocolate from sides of bottle. Remove from bath, cool, and add *basic Pb(OAc)<sub>2</sub> soln* (sp gr 1.25) to complete pptn (5 mL is usually enough). Add H<sub>2</sub>O to make total of 110 mL added liq. Mix thoroly, centr., and decant supernate thru small filter. Ppt excess Pb with powd dry K<sub>2</sub>C<sub>2</sub>O<sub>4</sub> and filter. Dil. 10 or 20 mL filtrate with equal vol. H<sub>2</sub>O, mix, and polarize in 200 mm tube at 20°. Obtain invert reading as in 31.026(b). Multiply both readings by 2 to obtain direct and invert polarizations "P" and "I." From data obtained, calc. % sucrose (S) from following formulas:

$$S = \frac{(P - I)(110 + X)}{143.0 - t/2},$$

where

$$X = \frac{0.2244(P - 21d)}{1 - 0.00204(P - 21d)},$$

where

$$d = \frac{P - I}{143.0 - t/2}.$$

### 13.050 Glucose (22)—Official First Action

Prep. clarified and deleded sample soln as in 13.049, except use only 10 g. Proceed as in 13.051 or 13.055.

## Glucose by Steinhoff Methods—Official First Action

### Zerban-Sattler Modification (23)

#### 13.051

#### Reagents

(a) *Soxhlet modification of Fehling copper soln.*—See 31.034(a).

(b) *Sodium acetate soln.*—Dissolve 500 g NaOAc.3H<sub>2</sub>O in ca 800 mL hot H<sub>2</sub>O, cool, and dil. to 1 L.

(c) *Potassium iodide-iodate soln.*—Dissolve 5.4 g KIO<sub>3</sub> and 60 g KI in H<sub>2</sub>O, add 0.25 g NaOH dissolved in little H<sub>2</sub>O, and dil. to 1 L.

(d) *Sulfuric acid.*—Approx. 2N. Dil. 57 mL H<sub>2</sub>SO<sub>4</sub> to 1 L.

(e) *Saturated potassium oxalate soln.*—Dissolve 165 g K<sub>2</sub>C<sub>2</sub>O<sub>4</sub>.H<sub>2</sub>O in 500 mL hot H<sub>2</sub>O, and cool.

(f) *Sodium thiosulfate std sol.*—0.1N Use std soln, 50.037–50.038. 1 mL 0.1N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 6.354 mg Cu.

(g) *Sugar soln.*—Dissolve amt of sample contg ca 10 g solids in H<sub>2</sub>O and dil. to 1 L.

#### 13.052

#### Determination

Transfer 10 mL Soxhlet soln, 20 mL NaOAc soln, 10 mL sugar soln, and 10 mL H<sub>2</sub>O to 250 mL erlenmeyer. Mix, close flask with rubber stopper provided with Bunsen valve, and immerse in briskly boiling H<sub>2</sub>O bath exactly 20 min. Immerse in cold running H<sub>2</sub>O, venting valve to prevent boiling caused by vac. Cool, add 25 mL KI-KIO<sub>3</sub> soln by pipet, and mix by gentle shaking. Rapidly add 40 mL 2N H<sub>2</sub>SO<sub>4</sub> from graduate; then add 20 mL K<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln from graduate. Shake until ppt completely dissolves, and titr. excess I with 0.1N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>.

Det. blank, substituting H<sub>2</sub>O for sugar soln. Difference between titer of blank and that of sample is direct measure of Cu<sub>2</sub>O pptd. From Table 13:02 obtain glucose equiv. corresponding to titer of 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>.

*Correction for reducing effect of maltose.*—If maltose is present, correct observed titer of 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> for reducing effect of maltose by subtracting correction obtained from Table 13:02 by interpolation.

#### Sichert-Bleyer Modification (24)

##### 13.053

##### Reagents

(a) *Ferric ammonium sulfate soln.*—Dissolve 120 g Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>·24H<sub>2</sub>O and 100 mL H<sub>2</sub>SO<sub>4</sub> in H<sub>2</sub>O and dil. to 1 L.

(b) *Potassium permanganate soln.*—0.1*N*. Prep as in 50.025.

##### 13.054

##### Standardization

To obtain factor for 0.1*N* KMnO<sub>4</sub> make analysis as in 13.055 on 10 mL soln contg 50 mg pure glucose. From Table 13:03, titer of 15.38 mL corresponds to 50 mg glucose; 15.38 divided by titer obtained gives correction factor for KMnO<sub>4</sub> soln. Multiply all titers by this factor before referring to Table 13:03. Redet. factor each day analyses are made.

##### 13.055

##### Determination

Proceed and in 13.052 thru "... immerse in briskly boiling H<sub>2</sub>O bath exactly 20 min." Filter Cu<sub>2</sub>O ppt thru gooch prepd as in 31.037, and wash flask and crucible 3 times with hot H<sub>2</sub>O. (It is not necessary to remove all ppt from flask.)

Transfer asbestos mat and crucible to 150 mL beaker marked at 60 mL. Wash flask with exactly 20 mL FeNH<sub>4</sub>(SO<sub>4</sub>)<sub>2</sub> soln in 3 portions and transfer quant. to beaker contg crucible. (All ppt must be dissolved.) Finally wash flask and crucible with hot H<sub>2</sub>O and remove crucible. Add hot H<sub>2</sub>O to 60 mL mark. Heat to bp on hot plate, let stand 3 min, and titr. with 0.1*N* KMnO<sub>4</sub>. Addn of 1 mL H<sub>3</sub>PO<sub>4</sub> toward end of titrn facilitates reading of end point. Pink-gray end point persists ca 20 sec. Multiply titer by factor and obtain mg glucose from Table 13:03.

#### STARCH—OFFICIAL FINAL ACTION

##### 13.056 Direct Acid Hydrolysis Method

(Caution: See 51.039, 51.054, and 51.070.)

Weigh 4 g sample if unsweetened, or 10 g if sweetened, into small porcelain mortar; add 25 mL ether and grind. After coarser material settles, decant ether, together with fine suspended matter, on 11 cm paper of fine enough texture to retain crude

Table 13:02 Zerban-Sattler Table for Determination of Glucose with Copper Acetate Reagent\*

starch. Repeat treatment until no more coarse material remains. After ether has evapd from filter, transfer fat-free residue to mortar by means of jet of cold H<sub>2</sub>O and rub to smooth paste, filtering on paper previously used. Repeat this process until all sugar is removed. (In case of sweetened products filtrate should measure  $\geq 500$  mL.) Det. crude starch in extd residue as in **8.019**.

See **12.043**, 10th ed.

## CHOCOLATE PRODUCTS

### Alginate (25)—Official Final Action

#### 13.058

#### Reagent

*Ferric hydroxide-sulfuric acid reagent*.—Dissolve 10 g FeCl<sub>3</sub>·6H<sub>2</sub>O in ca 100 mL H<sub>2</sub>O in each of 2 centr. bottles, and ppt Fe(OH)<sub>3</sub> by adding excess NH<sub>4</sub>OH (by odor). Wash ppt with ca 5 portions H<sub>2</sub>O, centrfg and decanting until little odor of NH<sub>3</sub> remains. Break up centrfd ppt each time before washing. Dry ppt on steam bath or in oven overnight, break up, and dry again. Mix with spatula or grind in mortar to obtain moderately fine powder. Keep in closed container.

Ferric hydroxide (moist) (ICN—K&K Laboratories, Inc.) may be used instead of pptg Fe(OH)<sub>3</sub> as above. Transfer this product to centr. bottles, shake, centr., decant, wash, and dry as above. Place 0.5 g dry powder in 50 mL g-s graduate, add 50 mL H<sub>2</sub>SO<sub>4</sub>, shake vigorously, and let settle until clear (usually 4–7 days). Some ferric sulfate appears to stick to sides, but reagent is ready for use after 7 days. Prep. fresh after 3 weeks. Check as follows before use:

Dissolve small amt (1–5 mg) of com. alginate in H<sub>2</sub>O contg 5 drops 0.1*N* NaOH, add 4 vols alcohol to ppt alginate, centr., decant, and dry on steam bath until no odor of alcohol remains, using air current to remove last traces of alcohol. Add 3 drops 0.1*N* NaOH, dissolve with aid of glass rod, and add 2 mL Fe-H<sub>2</sub>SO<sub>4</sub> reagent. Soln turns purple slowly, usually within 1 hr, depending on amt of algin present, but may take longer. If soln appears to be turning brown, add addnl 2 mL reagent, mix with glass rod, and let stand.

#### 13.059

#### Test

Weigh sample contg 10–20 mg alginate into 250 mL centr. bottle, add H<sub>2</sub>O to vol. of 40–50 mL, and dissolve by swirling. Adjust pH to 8–9 with *satd* Na<sub>3</sub>PO<sub>4</sub> *soln*; usually 5 drops is enough. Add ca 0.5 g *pancreatin* and 3 drops HCHO, and shake vigorously 1 min. Let stand 2–16 hr.

Centrf. at 1200 rpm 2–3 min, decant into 250 mL centr. bottle, and discard residue. Add 3–4 vols alcohol, shake, and let stand  $\geq 1$  hr, shaking several times. Centrf. as before and discard liq. Add 50 mL H<sub>2</sub>O and 1 drop 10% NaOH to residue and shake vigorously until no more residue appears to dissolve. Add 3 g decolorizing C (Nuchar) and shake vigorously 1 hr, preferably on shaking machine. Do not centr. but pour directly into folded filter paper, collecting filtrate in 250 mL centr. bottle. If filtrate is not clear, pour back thru paper several times. If filtration is slow, let filter overnight. Since C retains some alginate, for recovery of very small amts (ca 1 mg) re-ext C by shaking with another 50 mL portion H<sub>2</sub>O and 5 drops 0.1*N* NaOH, and add this filtrate to first extn.

To filtrate add 4 vols alcohol, shake, and let stand  $\geq 1$  hr, or overnight if convenient. Centrf. and decant, saving residue.

Residue contains alginates, gums, and gelatin. Dry residue on steam bath, using air current, if desired, until no odor of alcohol can be detected. Cool, add 3 drops 0.1*N* NaOH, and dissolve residue, using glass rod, as completely as possible. Add 2 mL Fe-H<sub>2</sub>SO<sub>4</sub> reagent, mixing with glass rod. If soln turns purple very soon, enough reagent was added; if brown appears, add addnl 2 mL reagent. Let stand overnight, since color develops slowly. Deep purple is pos. test for alginates. If test is neg., repeat detn, using twice the size sample, increasing Nuchar to 4 g, and shaking 1.5 hr, for confirmation.

### 13.060 THEOBROMINE (26)—OFFICIAL FINAL ACTION

(Caution: See **51.011** and **51.040**.)

(Not applicable to materials contg  $>ca$  12% sweetening ingredients)

Ext materials contg considerable fat, such as chocolate liquor or cacao nibs, with pet ether (bp  $<65^\circ$ ) to remove fat. (This preliminary extn is unnecessary with samples of cocoas or cacao shell.)

Place 10 g sample or prepd sample in small porcelain dish. Add 2–3 g freshly *calcined* MgO and mix well with flat-end glass rod. Add H<sub>2</sub>O, few mL at time, and triturate carefully and thoroly until every particle is damp (9–20 mL, usually 14 mL; material should be compressible to firm cake). Place dish contg damp mixt. on steam bath 30 min, mixing at intervals to prevent any part from becoming dry, during which time material should granulate.

After 30 min, remove dish and triturate mixt. well so that every particle is damp; then transfer to 250 mL flask. Add 150 mL *tetrachloroethane*, attach air condenser, and boil 30 min. Filter nearly boiling hot liq. into second ca 200 mL flask, preferably with  $\frac{3}{4}$  joint. (Filtrate should be clear and almost colorless.)

Transfer residue and filter to first flask with 120 mL addnl solv. and again reflux 20–30 min. Meanwhile, distil most of liq. in second flask from first extn thru air condenser. Filter hot liq. (second extn) into second flask and repeat process of refluxing and distn twice more, using 120 mL portions *tetrachloroethane*. Receive filtrates from all extns in flask 2, intermittently distg off portions as above. Distil liq. after last extn until reduced to 3–5 mL.

Cool flask and residue, and add 65 mL ether with rotation; mix well, stopper, and let stand  $\geq 1$  hr (until supernate is clear). Collect ppt on tared filter paper, using several 5–7 mL portions ether to transfer and wash. Dry filter and ppt at 100°, and weigh. Add 0.004 g to wt found to compensate for theobromine dissolved in the ether. Calc. % theobromine in original material.

## 14. Cereal Foods

### WHEAT FLOUR (1)

#### 14.001 Sampling—Official Final Action

Sample number of sacks equiv. to sq root of number in lot, but  $\geq 10$ , i.e., 10 from  $\leq 100$ , 15 from 225, 20 from 400 sacks, etc.

Select sacks to be sampled according to their exposure in ratio of 4 from most exposed, 3 from next less exposed, 2 from next, and 1 from least exposed portion of lot.

From each sack to be sampled, draw core from one corner of top diagonally to center of sack by means of cylindrical, pointed, polished metal trier,  $\frac{1}{2}$ " (13 mm) diam., with slit  $\geq \frac{1}{3}$  of circumference. Draw second core from other top corner to  $\frac{1}{2}$  distance to center of sack.

Deliver the 2 cores at once to clean, dry, air-tight container that has stood open for few min near lot of flour to be sampled, and seal immediately. Use sep. container for each sack sampled. Use one of following containers: (1) pt (500 mL) fruit jar provided with rubber gasket; (2) rubber or plastic pouch that can be tied or sealed to exclude moisture or air; (3) tin can or box with moisture- and air-tight friction top.

Before opening sample for analysis, alternately invert and roll each container  $\geq 25$  times to secure homogeneous mixt. Avoid extreme temps and humidities when opening containers for analysis. Keep sample tightly sealed at all other times.

#### Total Solids (Moisture, Indirect Method)

(Also applicable to flour mixes contg  $\text{NaHCO}_3$  as ingredient)

#### Vacuum Oven Method (2)—Official Final Action

##### 14.002

##### Apparatus

(a) *Metal dish*.—Diam. ca 55 mm, ht ca 15 mm, with inverted slip-in cover fitting tightly on inside.

(b) *Air-tight desiccator*.—Reignited CaO is satisfactory drying agent.

(c) *Vacuum oven*.—Connect with pump capable of maintaining partial vac. in oven with pressure equiv. to  $\leq 25$  mm Hg (3.3 kPa) and provided with thermometer passing into oven in such way that bulb is near samples. Connect  $\text{H}_2\text{SO}_4$  gas-drying bottle with oven to admit dry air when releasing vac.

##### 14.003

##### Determination

Accurately weigh ca 2 g well mixed sample in covered dish previously dried at 98–100°, cooled in desiccator, and weighed soon after reaching room temp. Loosen cover (do not remove) and heat at 98–100° to const wt (ca 5 hr) in partial vac. having pressure equiv. to  $\leq 25$  mm Hg (3.3 kPa). Admit dry air into oven to bring to atm. pressure. Immediately tighten cover on dish, transfer to desiccator, and weigh soon after reaching room temp. Report flour residue as total solids and loss in wt as moisture (indirect method).

#### 14.004 Air Oven Method (3)—Official Final Action

(Results closely approximate those obtained by 14.003.)

In cooled and weighed dish (provided with cover), 14.002(a), previously heated to  $130 \pm 3^\circ$ , accurately weigh ca 2 g well mixed sample. Uncover sample, and dry dish, cover, and contents 1 hr in oven provided with opening for ventilation and maintained at  $130 \pm 3^\circ$ . (1 hr drying period begins when oven temp. is actually  $130^\circ$ .) Cover dish while still in oven, transfer to desic-

cator, and weigh soon after reaching room temp. Report flour residue as total solids and loss in wt as moisture (indirect method).

#### 14.005 Extract Soluble in Cold Water (4) Official Final Action

Weigh 20 g flour into 500 mL erlenmeyer and gradually add 200 mL  $\text{H}_2\text{O}$  at ca  $0^\circ$ . Shake vigorously after ca 50 mL  $\text{H}_2\text{O}$  is added and continue shaking while adding remaining  $\text{H}_2\text{O}$ . Let mixt. stand 40 min at  $0^\circ$ , shaking occasionally. Filter rapidly, returning filtrate to filter until clear. Pipet 20 mL clear filtrate into weighed dish, evap. to dryness on steam bath, and dry in vac. oven at ca  $100^\circ$  for 30 min periods to const wt.

#### Ash (5)

#### 14.006 Direct Method—Official Final Action

Weigh 3–5 g well mixed sample into shallow, relatively broad ashing dish that has been ignited, cooled in desiccator, and weighed soon after reaching room temp. Ignite in furnace at ca  $550^\circ$  (dull red) until light gray ash results, or to const wt. Cool in desiccator and weigh soon after reaching room temp. Reignited CaO is satisfactory drying agent for desiccator.

#### Magnesium Acetate Method (6)—Official Final Action

##### 14.007

##### Reagent

*Magnesium acetate soln.*—Dissolve 4.054 g  $\text{Mg}(\text{OAc})_2 \cdot 4\text{H}_2\text{O}$  in 50 mL  $\text{H}_2\text{O}$  and dil. to 1 L with alcohol.

##### 14.008

##### Determination

From buret add 5 mL of the reagent to 3–5 g flour, bread, etc., or 10 mL to 1 g bran, wheat germ, etc. Let stand 1–2 min, evap. excess alcohol, and place in furnace at  $700^\circ$ , closing door after flaming ceases. When incineration is complete, place dish in desiccator until cool; then weigh. Det. blank on soln and deduct blank from wt ash. Evap. blank cautiously.

#### Original Ash of Flour in Phosphated and Self-Rising Flour (7)

(Caution: See 51.040 and 51.049.)

#### 14.009 Gustafson Method—Official Final Action

To 20–25 g sample in metal centr. tube (cup 2" diam., 6" deep), add enough  $\text{CCl}_4$  to fill tube to within 25 mm of top (ca 250 mL). Centr. 5–7 min at 1600 rpm and let centr. come to rest slowly. With large tablespoon, carefully skim off flour, which is in compact layer on surface of  $\text{CCl}_4$ , recovering as much flour as possible in 1 spoonful. (With care, ca 90% of original flour may be recovered.) Let wet flour dry overnight and proceed as in 14.006. ( $\text{CCl}_4$  may be filtered, distd, and used again.)

#### 14.010 Added Inorganic Material in Phosphated Flour (8)—Official Final Action

Transfer 20 g flour to dry 250 mL separator, add ca 200 mL  $\text{CCl}_4$ , shake well, and let stand until soln at bottom is nearly clear, usually ca 15 min. Draw off sediment with min. of soln, by turning stopcock quickly from side to side, into 100 mL  $\text{CCl}_4$  in dry 125 mL separator. Again shake 250 mL separator and let

stand, with occasional gentle swirling if necessary to dislodge sediment from sides, until lower portion of soln clears. Draw off sediment from 125 mL separator into prepd and weighed gooch, using suction. Draw off sediment from 250 mL separator into 125 mL separator as before, and let stand with occasional gentle swirling to dislodge sediment from sides of separator. After lower portion of liq. clears, draw off into gooch as before, taking care that no sediment remains on ledge in separator. Wash crucible and contents with 25 mL fresh  $\text{CCl}_4$ , continue aspirating 2 or 3 min, weigh at once, and report as % added phosphate. Ignite crucible at  $700^\circ$ , cool, and weigh as  $\text{Ca}(\text{PO}_3)_2$ .

$\text{Wt } \text{Ca}(\text{PO}_3)_2 \times 1.27 \times 5 = \% \text{ Ca}(\text{H}_2\text{PO}_4)_2 \cdot \text{H}_2\text{O} \text{ in flour.}$

#### Iron (9)—Official Final Action

(Applicable to enriched, enriched self-rising, and phosphated flours. Rinse all flasks, beakers, funnels, etc., with  $\text{H}_2\text{O}$  before use, and filter all reagents to remove suspended matter.)

##### 14.011

##### Reagents

(a) *Orthophenanthroline soln.*—Dissolve 0.1 g *o*-phenanthroline in ca 80 mL  $\text{H}_2\text{O}$  at  $80^\circ$ , cool, and dil. to 100 mL.

(b) *Alpha, alpha-dipyridyl soln.*—Dissolve 0.1 g  $\alpha, \alpha$ -dipyridyl in  $\text{H}_2\text{O}$  and dil. to 100 mL.

(Reagents (a) and (b) kept in cool, dark place will remain stable several weeks.)

(c) *Iron std soln.*—0.01 mg Fe/mL. (1) Dissolve 0.1 g anal. grade Fe wire in 20 mL HCl and 50 mL  $\text{H}_2\text{O}$ , and dil. to 1 L. Dil. 100 mL of this soln to 1 L. Or—(2) Dissolve 3.512 g  $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 2 drops HCl, and dil. to 500 mL. Dil. 10 mL of this soln to 1 L.

(d) *Hydroxylamine hydrochloride soln.*—Dissolve .10 g  $\text{H}_2\text{NOH} \cdot \text{HCl}$  in  $\text{H}_2\text{O}$  and dil. to 100 mL.

(e) *Magnesium nitrate soln.*—Dissolve 50 g  $\text{Mg}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 100 mL.

(f) *Acetate buffer soln.*—Dissolve 8.3 g anhyd. NaOAc (previously dried at  $100^\circ$ ) in  $\text{H}_2\text{O}$ , add 12 mL HOAc, and dil. to 100 mL. (It may be necessary to redistil the HOAc and recrystallize the NaOAc from  $\text{H}_2\text{O}$ , depending on amt of Fe present.)

(g) *Sodium acetate soln.*—2M. Dissolve 272 g  $\text{NaOAc} \cdot 3\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(h) *Buffer soln, pH 3.5.*—Dil. 6.4 mL 2M NaOAc soln, (g), and 93.6 mL 2M HOAc (120 g/L) to 1 L with  $\text{H}_2\text{O}$ .

##### 14.012

##### Preparation of Standard Curve

Prep. 11 solns contg 0.0, 2.0, 5.0, 10.0, 15.0, 20.0, 25.0, 30.0, 35.0, 40.0, and 45.0 mL, resp., of the final dild Fe std soln, plus 2.0 mL HCl, in 100 mL. Using 10 mL of each of these solns, proceed as in 14.013, beginning "... add 1 mL  $\text{H}_2\text{NOH} \cdot \text{HCl}$  ..." Plot concn against scale reading.

##### 14.013

##### Determination

(a) *By dry ashing.*—Ash 10.0 g flour in Pt,  $\text{SiO}_2$ , or porcelain dish (ca 60 mm diam., 35 mL capacity) as in 14.006. (Porcelain evapg dishes of ca 25 mL capacity are satisfactory. Do not use flat-bottom dishes of diam.  $>60$  mm.) Cool, and weigh if % ash is desired. Continue ashing until practically C-free. To diminish ashing time, or for samples that do not burn practically C-free, use one of following ash aids:

Moisten ash with 0.5–1.0 mL  $\text{Mg}(\text{NO}_3)_2$  soln or with redistd  $\text{HNO}_3$ . Dry and carefully ignite in furnace, avoiding spattering. (White ash with no C results in most cases.) Do not add these ash aids to self-rising flour (products contg NaCl) in Pt dish because of vigorous action on dish. Cool, add 5 mL HCl, letting acid rinse upper portion of dish, and evap. to dryness on steam bath. Dissolve residue by adding 2.0 mL HCl, accurately meas-

ured, and heat 5 min on steam bath with watch glass on dish. Rinse watch glass with  $\text{H}_2\text{O}$ , filter into 100 mL vol. flask, cool, and dil. to vol.

Pipet 10 mL aliquot into 25 mL vol. flask, and add 1 mL  $\text{H}_2\text{NOH} \cdot \text{HCl}$  soln; in few min add 5 mL buffer soln, (f), and 1 mL *o*-phenanthroline or 2 mL dipyridyl soln, and dil. to vol. Det. A in spectrophtr or photometer at ca 510 nm. From reading, det. Fe concn from equation of line representing std points or by ref. to std curve for known Fe concn. Det. blank on reagents and make correction. Calc. Fe in flour as mg/lb.

(b) *By wet digestion.*—(Caution: See 51.011, 51.019, 51.026, and 51.030.) Transfer 10.00 g flour to 800 mL Kjeldahl flask, previously rinsed with dil. acid, then with  $\text{H}_2\text{O}$ ; add 20 mL  $\text{H}_2\text{O}$  and mix; pipet 5 mL  $\text{H}_2\text{SO}_4$  into flask and mix; add 25 mL  $\text{HNO}_3$  and mix well. After few min, heat flask very gently at brief intervals (to avoid foaming out of flask) until heavy evolution of  $\text{NO}_2$  fumes ceases. Continue to heat gently until material begins to char; then add few mL  $\text{HNO}_3$  cautiously at intervals until  $\text{SO}_3$  fumes evolve and colorless or very pale yellow liq. is obtained (60–65 mL  $\text{HNO}_3$  total in ca 2 hr). Cool, add 50 mL  $\text{H}_2\text{O}$  and 1 Pyrex glass bead, and heat to  $\text{SO}_3$  fumes; cool, add 25 mL  $\text{H}_2\text{O}$ , and filter quant. thru 11 cm paper into 100 mL vol. flask; cool, and dil. to vol.

Pipet 10 mL into 25 mL vol. flask, add 1 mL  $\text{H}_2\text{NOH} \cdot \text{HCl}$  soln, rotate flask, and let stand few min. Add 9.5 mL 2M NaOAc soln, (g), and 1 mL *o*-phenanthroline soln, dil. to vol., and mix. Let stand  $\geq 5$  min and det. A in spectrophtr or photometer at ca 510 nm.

With self-rising flour, the 9.5 mL 2M NaOAc soln, (g), may be reduced to 8.0 mL. To det. exact amt of buffer soln, (g), needed to adjust each digest to most desirable pH range, mix 10 mL aliquot of sample with measured amt of buffer soln, (g), dil. with  $\text{H}_2\text{O}$  to 25 mL, and det. pH either potentiometrically or colorimetrically.

For colorimetric detn, add 5 drops bromophenol blue indicator, 6.019(f), to soln and compare color with that of equal vol. of pH 3.5 buffer soln, (h), also treated with 5 drops indicator. Altho color develops from pH 2–9, avoid pH  $<3.0$  and preferably work at pH 3.5–4.5. With cereal products, 9.5 mL buffer soln, (g), is satisfactory. With samples high in Fe, aliquot of 5 mL instead of 10 mL may be used with 4.8 mL buffer soln, (g).

Conduct digestion so as to avoid contamination with Fe, and det. blank. After correction for blank, calc. as mg Fe/lb.

##### 14.014 Calcium (10)—Official Final Action

(Applicable to enriched, enriched self-rising, and phosphated flours)

Ash 10 g flour or air-dried bread as in 14.006, and proceed as in 14.013(a) thru "Rinse watch glass with  $\text{H}_2\text{O}$ , ...", then filter into 400 mL beaker; or transfer 50 mL soln from Fe detn to 400 mL beaker. Dil. to ca 150 mL.

Add 8–10 drops bromocresol green indicator, 50.008, and enough 20% NaOAc soln to change pH to 4.8–5.0 (blue). Cover with watch glass and heat to bp. Ppt Ca slowly by adding 3% oxalic acid soln, 1 drop every 3–5 sec, until pH is 4.4–4.6 (optimum for Ca oxalate pptn) as indicated by distinct green shade. (Avoid excess of oxalic acid indicated by yellow tints, showing undesirable displacement of pH.) Boil 1–2 min and let mixt. settle until clear or overnight. Filter supernate thru quant. paper, gooch, or fine fritted glass filter, and wash beaker and ppt with ca 50 mL  $\text{NH}_4\text{OH}$  (1+50) in small portions, using wash bottle delivering very small stream. Break point of filter and wash filter or crucible with mixt. of 125 mL  $\text{H}_2\text{O}$  and 5 mL  $\text{H}_2\text{SO}_4$  at  $80$ – $90^\circ$ . Titr. at  $70$ – $90^\circ$  with 0.05N  $\text{KMnO}_4$  until slight pink is obtained, add filter paper, and continue titrn if necessary. Correct for blank and calc. Ca as mg/lb. 1 mL 0.05N  $\text{KMnO}_4 = 1$  mg Ca.

**Phosphorus (11)—Official Final Action****14.015****Reagent**

(a) *Magnesium nitrate soln.*—Dissolve 8 g MgO in HNO<sub>3</sub> (1+1), avoiding excess acid; add little MgO in excess, boil, filter from excess MgO, Fe<sub>2</sub>O<sub>3</sub>, etc., and dil. to 100 mL.

(b) *Molybdate soln.*—See 7.118(a).

**14.016****Determination**

(a) Transfer 1.00 g sample to ca 140 mL porcelain casserole, add 3 mL Mg(NO<sub>3</sub>)<sub>2</sub> soln, and mix well, using small glass rod. Clean rod with small piece filter paper and place in casserole. Dry in oven at 100° ca 2 hr, transfer to cold furnace, and ignite at 550° to white or gray ash (6–8 hr). Cool, cover with watch glass, take up with 10 mL HCl (1+4), and add 5 mL HCl. Rinse watch glass and evap. to dryness on steam bath. Add 5 mL HCl and 50 mL H<sub>2</sub>O, heat 15 min on steam bath, filter into 100 mL vol. flask, cool, and dil. to vol. Pipet 50 mL into 300 mL erlenmeyer, neutze to litmus paper with NH<sub>4</sub>OH, make just faintly acid with HNO<sub>3</sub>, dil. to 75–100 mL, add ca 15 g NH<sub>4</sub>NO<sub>3</sub>, and proceed as in 7.119, beginning "Add . . . enough acidified molybdate soln to ensure complete pptn . . ." Or—

(b) Transfer 5.00 g sample to 35 mL porcelain evapg dish, mix well with 0.5 g Na<sub>2</sub>CO<sub>3</sub>, and ignite at 550° to gray ash. Cool, cover with watch glass, take up with 2 mL HCl (1+4), and add 5 mL HCl. Rinse watch glass, evap. to dryness, add 5 mL HCl and 10 mL H<sub>2</sub>O, heat ca 10 min on steam bath, filter into 100 mL vol. flask, cool, and dil. to vol. Pipet 10 mL aliquot into 300 mL erlenmeyer and proceed as in (a), beginning "... neutze to litmus paper with NH<sub>4</sub>OH, . . ."

Report results as % P.

**14.017 Total Carbon Dioxide in Self-Rising Flour (12)  
Official Final Action**

(Not applicable to flours contg added CaCO<sub>3</sub>)

Use 17 g flour, 15–20 glass beads (4–6 mm diam.), and 45 mL H<sub>2</sub>SO<sub>4</sub> (1+5). Proceed as in 8.002–8.004, as far as calcn, except agitate flask vigorously 3 min and let stand 10 min to attain equilibrium.

Calc. as follows: Subtract vol. acid used from total buret reading and correct for temp. and pressure. Divide reading by 100 to obtain % CO<sub>2</sub> (by wt). Correct apparent % CO<sub>2</sub> to compensate for varying atm. conditions by immediately assaying synthetic sample of known composition and like ingredients by same method in same app. Divide wt CO<sub>2</sub> recovered from synthetic sample by wt CO<sub>2</sub> contained in NaHCO<sub>3</sub> used and record quotient. Apparent % total CO<sub>2</sub> in official sample ÷ this quotient = corrected % total CO<sub>2</sub> in sample.

**14.018 Crude Fat or Ether Extract—Official Final Action**

Proceed as in 7.056; with fine flour, addn of equal wt clean, dry sand may be necessary.

**14.019 Fat (Acid Hydrolysis Method) (13)  
Official Final Action**

(Caution: See 51.011(a), 51.054, and 51.073.)

Place 2 g sample in 50 mL beaker, add 2 mL alcohol, and stir to moisten all particles to prevent lumping on addn of acid. Add 10 mL HCl (25+11), mix well, set beaker in H<sub>2</sub>O bath held at 70–80°, and stir at frequent intervals during 30–40 min. Add 10 mL alcohol and cool.

Transfer mixt. to Mojonnier fat-extn app. Rinse beaker into extn tube with 25 mL ether, added in 3 portions; stopper flask

(with glass, cork, Neoprene, or other synthetic rubber stopper not affected by solvs) and shake vigorously 1 min. Add 25 mL redistd pet ether (bp <60°) and again shake vigorously 1 min. Let stand until upper liq. is practically clear, or centrf. 20 min at ca 600 rpm.

Draw off as much as possible of ether-fat soln thru filter consisting of cotton pledget packed just firmly enough in funnel stem to let ether pass freely into weighed 125 mL beaker-flask contg porcelain chips or broken glass. Before weighing beaker-flask, dry it and similar flask as counterpoise in oven at 100°; then let stand in air to const wt.

Re-ext liq. remaining in tube twice, each time with only 15 mL of each ether. Shake well on addn of each ether. Draw off clear ether solns thru filter into same flask as before and wash tip of spigot, funnel, and end of funnel stem with few mL of mixt. of the 2 ethers in equal vols, free from suspended H<sub>2</sub>O. Evap. ethers slowly on steam bath; then dry fat in oven at 100° to const wt (ca 90 min). Remove flask and counterpoise from oven, let stand in air to const wt (ca 30 min), and weigh. (Owing to size of flask and nature of material, there is less error by cooling in air than by cooling in desiccator.) Correct this wt by blank detn on reagents used. Report as % fat by acid hydrolysis.

**14.020 Crude Fiber—Official Final Action**

See 7.065.

**14.021 Fat Acidity (14)—Official Final Action**

See 14.072.

**Hydrogen-Ion Activity (pH)—Official Final Action****14.022 Potentiometric Method (15)**

Weigh 10.0 g sample into clean, dry erlenmeyer and add 100 mL recently boiled H<sub>2</sub>O at 25°. Shake until particles are evenly suspended and mixt. is free of lumps. Digest 30 min, shaking frequently. Let stand 10 min more, decant supernate into the H-ion vessel, and immediately det. pH, using electrode and potentiometer stdzd by buffer solns of pH 4.01, 50.007(c), and of pH 9.18, 50.007(f), both at 25°.

**Reducing and Nonreducing Sugars (16)  
Official Final Action****14.023****Reagents**

(a) *Acetate buffer soln.*—Dil. 3 mL HOAc, 4.1 g anhyd. NaOAc, and 4.5 mL H<sub>2</sub>SO<sub>4</sub> to 1 L with H<sub>2</sub>O.

(b) *Sodium tungstate soln.*—12%. Dil. 12.0 g Na<sub>2</sub>WO<sub>4</sub>·2H<sub>2</sub>O to 100 mL with H<sub>2</sub>O.

(c) *Alkaline ferricyanide soln.*—0.1N. 33.0 g pure dry K<sub>3</sub>Fe(CN)<sub>6</sub> and 44.0 g Na<sub>2</sub>CO<sub>3</sub>/L.

(d) *Acetic acid-salts soln.*—Dil. 200 mL HOAc, 70 g KCl, and 40 g ZnSO<sub>4</sub>·7H<sub>2</sub>O to 1 L with H<sub>2</sub>O.

(e) *Soluble starch-potassium iodide soln.*—Add 2 g sol. starch to small amt cold H<sub>2</sub>O and pour slowly into boiling H<sub>2</sub>O with const stirring. Cool thoroly (or resulting mixt. will be dark colored), add 50 g KI, and dil. to 100 mL with H<sub>2</sub>O. Add 1 drop NaOH soln (1+1). Use 1 mL.

(f) *Thiosulfate std soln.*—0.1N. 24.82 g Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O and 3.8 g Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O/L.

Make blank detn with each day's series of sugar detns to guard against changes in the K<sub>3</sub>Fe(CN)<sub>6</sub> soln and correct for any reducing impurities in reagents as follows:

Combine 5 mL alcohol, 50.0 mL acetate buffer soln, and 2 mL Na tungstate soln. To 5 mL of this mixt. (used in place of 5 mL

flour ext) add 10.0 mL  $K_3Fe(CN)_6$  soln and proceed as in 14.025(a). (10.0 mL  $Na_2S_2O_3$  soln should discharge the blue starch-I color.) If titrn falls within  $10 \pm 0.05$  mL do not discard reagents but correct in subsequent sugar calcs by using  $Na_2S_2O_3$  equiv. of 10 mL  $K_3Fe(CN)_6$  soln (*i.e.*, mL  $Na_2S_2O_3$  soln required in above titrn) instead of 10.0 as basis for subtraction.

**14.024****Preparation of Extract**

Place 5.675 g flour in 100 or 125 mL erlenmeyer. Tip flask so that all flour is at one side; then wet flour with 5 mL alcohol. Tip flask so that wet flour is at upper side and add 50.0 mL acetate buffer soln, keeping soln from coming in contact with flour until all is added to flask. Then shake flask to bring flour into suspension. Immediately add 2 mL Na tungstate soln and again mix thoroly. Filter at once (Whatman No. 4, or equiv.), discarding first 8–10 drops filtrate.

**14.025****Determination**

(a) *Reducing sugars*.—Pipet 5 mL flour ext into ca 75 mL test tube (Pyrex 25 × 200 mm). Add exactly 10 mL  $K_3Fe(CN)_6$  soln

to test tube, mix, and immerse in vigorously boiling  $H_2O$  bath so that liq. in tube is 3–4 cm below surface of boiling  $H_2O$ .

After exactly 20 min in boiling  $H_2O$  bath, cool tube under running  $H_2O$ , and pour at once into 100 or 125 mL erlenmeyer. Rinse test tube with 25 mL HOAc-salts soln, (d), add to erlenmeyer, and mix thoroly. Then add 1 mL starch-KI soln. Titrate with 0.1N  $Na_2S_2O_3$  soln until blue completely disappears (10 mL micro buret recommended). Subtract mL 0.1N  $Na_2S_2O_3$  used in titrn from 10.00. In case of slight blank in  $K_3Fe(CN)_6$ - $Na_2S_2O_3$  titrn, correct by subtracting from  $Na_2S_2O_3$  equiv. of  $K_3Fe(CN)_6$  soln. This difference represents definite amt of reducing sugar/10 g flour, calcd as maltose from Table 14.01.

(b) *Nonreducing sugars*.—Pipet 5 mL flour ext into 20 cm test tube and immerse in vigorously boiling  $H_2O$  bath. After boiling 15 min, cool under running  $H_2O$  and add exactly 10 mL  $K_3Fe(CN)_6$  soln. Proceed as in (a).  $K_3Fe(CN)_6$  reduced after hydrolysis –  $K_3Fe(CN)_6$  reduced by maltose in flour = nonreducing sugars calcd as sucrose and detd from Table 14.01.

**14.026 Total Protein—Official Final Action**

Det N as in 2.057, and multiply % N by 5.7 to obtain % protein.

**Table 14.01. 0.1N Ferricyanide Maltose-Sucrose Conversion Table<sup>a</sup>**

0.1N Ferricyanide Reduced mL	Maltose per 10 g Flour mg	Sucrose per 10 g Flour mg	0.1N Ferricyanide Reduced mL	Maltose per 10 g Flour mg	Sucrose per 10 g Flour mg

<sup>a</sup> These values are arbitrarily given for 10 g flour altho detn is made on only 0.5 g flour.

#### 14.027 Water-Soluble Protein-Nitrogen Precipitable by 40 Per Cent Alcohol (17)—Official Final Action

Weigh 20 g sample (20-mesh or finer) into 250 mL centr. bottle. Pipet in 100 mL H<sub>2</sub>O, shaking bottle to prevent lumping of sample. Add 100 mL more H<sub>2</sub>O from pipet. Stopper bottle and shake 1 hr in shaking machine or by hand. (Preferably use horizontal shaker with bottle lengthwise. If vertical wrist-type motion machine is used, shake by hand 5 min after the 1 hr shaking.) Temp. of H<sub>2</sub>O should be  $\leq 30^\circ$ . Centrf. at 1200 rpm ca 15 min and filter into 500 mL suction flask thru pad of fine asbestos on buchner (51 mm diam.), using suction. Det. N in 50 mL filtrate as in 2.057 with glass bead in each flask, distg NH<sub>3</sub> into 20 mL 0.1N acid. Digest 1 hr after clear. Correct for blank on reagents used in digestion.

Pipet 100 mL of above filtrate into 200 mL vol. flask, add 15 mL NaCl soln (28 g dild to 300 mL), fill nearly to mark with alcohol, mix well, cool to room temp., dil. to vol., mix, and let stand overnight. Pipet off supernate and filter thru 18.5 cm fluted paper (S&S 588, or equiv.). Det. N in 100 mL filtrate as above, using glass bead to avoid bumping. Add H<sub>2</sub>SO<sub>4</sub>, mix, and carefully boil off alcohol before adding Na<sub>2</sub>SO<sub>4</sub>-HgO mixt. Rinse Na<sub>2</sub>SO<sub>4</sub>-HgO mixt. down neck of flask. Digest 1 hr after clear. (Watch for foaming before clearing and keep contents out of neck of flask.) Distil into 20 mL 0.1N acid as before. Correct for blank on reagents used in digestion. Subtract this number of mL acid used from number of mL acid used for H<sub>2</sub>O-sol. N detn and convert to % H<sub>2</sub>O-sol. N precipitable by 40% alcohol.

#### 14.028 Lipids (18)—Official Final Action

(Caution: See 51.005, 51.011, 51.054, and 51.055.)

Add 15 mL alcohol, 70% by vol., to 5 g sample (20-mesh or finer) in 250 mL centr. bottle. Give bottle gentle rotary motion so as to moisten all particles, stopper firmly (to keep in place during heating), and set in H<sub>2</sub>O bath kept at 75–80°. (Consider that temp. of bath may drop when bottles are introduced.) Heat 15 min, mixing frequently with same rotary motion. Immediately add 27 mL alcohol, stopper bottle, and *shake vigorously* 2 min. Cool, add 45 mL ether, and shake vigorously 5 min. (Sample should now be finely divided.) Centrf. at ca 1000 rpm few min and decant into 250 mL beaker contg some bits of broken porcelain or glass; rinse bottle neck with ether. Re-ext sample with three 20 mL portions ether, shaking ca 2 min each time, centrfg, and decanting into beaker contg first ext. Break up sample each time with glass stirring rod, rinsing with ether on removal.

Evap. combined ether-alcohol exts just to dryness on steam bath. Drive off any remaining moisture on sides of beaker by placing in oven 5 min at 100°. Dissolve dry ext in ca 15 mL CHCl<sub>3</sub> and filter soln into previously dried and weighed 100 mL Pt dish thru asbestos mat 3–4 mm thick, covered with ca 10 mm layer of sand in Knorr-type extn tube (20 mm diam.  $\times$  11 cm long; stem 10 cm long). Wash sides of dish and tube with 10 mL and two 5 mL portions CHCl<sub>3</sub>. With glass rod, free any solid ext adhering to dish to be sure all lipids dissolve. Finally wash tube and tip with 5 mL CHCl<sub>3</sub>. Evap. CHCl<sub>3</sub> on steam bath and dry in oven at 100° to const wt. (ca 90 min). Weigh. Report ext as lipids.

#### 14.029 Lipid Phosphorus (18)—Official Final Action

Wash sides of Pt dish with 10 mL CHCl<sub>3</sub> to dissolve lipids, 14.028; likewise wash sides of dish with 10 mL 4% a/c. KOH soln. Cautiously evap. to dryness on steam bath and ash 1 hr at 500°. Cover dish with watch glass, add 15 mL HNO<sub>3</sub> (1+9) to make soln definitely acid, heat on steam bath ca 5 min, and

filter into 300 mL erlenmeyer. Wash residue and filter with ca 25 mL hot H<sub>2</sub>O. Make soln slightly alk. to litmus paper with NH<sub>4</sub>OH from Mohr pipet and then slightly acid with HNO<sub>3</sub> (1+9). Keep vol.  $<ca$  60 mL. Add 20 mL NH<sub>4</sub>NO<sub>3</sub> soln (500 g dild to 1 L), and heat in H<sub>2</sub>O bath to 45–50°. Add 20 mL freshly prepd and filtered molybdate soln, 7.118(a), and let flasks remain in bath 30 min at 40–45°, swirling contents at ca 5 min intervals. To prevent tipping, weight flask with lead rings or by other means.

For filtration, use filter tube (so-called carbon filter), ca 28 mm id, fitted with removable, perforated porcelain disk from Caldwell crucible. (Caldwell crucible or gooch may also be used.) Prep. quick filtering pad 3–4 mm thick, using short-fiber asbestos. For convenience in washing and in transferring filter tubes, provide suction flask with rubber stopper having hole somewhat larger than stem of filter tube.

With full suction, filter ppt and wash flask and then filter tube with ca 6 portions cold H<sub>2</sub>O, using 150–200 mL total. Test for complete washing by passing 25 mL CO<sub>2</sub>-free H<sub>2</sub>O thru flask and filter tube into clean suction flask. Immediately disconnect suction and add 1 drop each of 0.1N NaOH and phthln, which should yield strong pink color.

Loosen pad and porcelain disk with wire or narrow rod inserted in stem end, and transfer to flask. Place filter tube in neck of flask, dissolve any ppt on walls with measured vol. std alkali, and rinse down filter tube with ca 25 mL CO<sub>2</sub>-free H<sub>2</sub>O. (Enough std alkali must have been added to dissolve ppt.) Stopper flask, swirl, and let stand, mixing occasionally, until yellow ppt completely dissolves. Dil. to ca 75 mL with CO<sub>2</sub>-free H<sub>2</sub>O, add 10 drops phthln, and titr. with std acid to complete disappearance of pink, matching end point with another flask contg H<sub>2</sub>O and asbestos only. If alkali adheres to fragments of asbestos, making end point uncertain, add slight excess of std acid and complete titrn with std alkali. 1 mL 0.1N NaOH = 0.3086 mg P<sub>2</sub>O<sub>5</sub>. Subtract alkali consumed in blank detn.

#### 14.030 Unsaponifiable Residue—Official Final Action

See 14.147.

#### Starch (19)—Official First Action

##### 14.031

##### Reagent

*Calcium chloride soln.*—Dissolve 2 parts CaCl<sub>2</sub>·6H<sub>2</sub>O in 1 part H<sub>2</sub>O and adjust to density of 1.30 at 20° (soln contains ca 33% CaCl<sub>2</sub>). Make faintly pink to phthln by adding 0.1N NaOH. (Anhyd. CaCl<sub>2</sub> may be used, but it is usually alk. and requires addn of acid to bring it to correct pH.)

##### 14.032

##### Determination

Grind sample finely (100-mesh if possible) and weigh 2.0–2.5 g into 50 mL r-b centr. tube with lip. Wash with ether to remove fat, then with 10 mL ca 65% by wt alcohol ( $d_{20} = 0.88$ ), and stir thoroly with glass rod. Centrf. (if no centr. is available, wash samples on filter paper, using Pt cone and slight suction) and pour off soln. Repeat washing until 60 mL wash liq. has been used, stirring each time with same rod.

Stir residue with 10 mL H<sub>2</sub>O and pour into 200–250 mL erlenmeyer. Complete transfer by washing with total of 60 mL CaCl<sub>2</sub> soln contg 2 mL 0.8% HOAc. Transfer rod to flask and bring mixt. to bp quickly over wire gauze, stirring frequently. Boil briskly 15–17 min, taking precautions to prevent burning and foaming. Rub down particles on sides of flask with rod from time to time.

Cool soln quickly in running H<sub>2</sub>O and pour into 100 mL vol. flask, rinsing thoroly with CaCl<sub>2</sub> soln from wash bottle with

medium jet. In dilg to vol., add 1 drop alcohol, if necessary to destroy froth.

After thoroly mixing sample, pour ca 10 mL soln onto fluted filter (Whatman 42 or 44), wetting paper completely. Let filter run dry and discard filtrate. Resume filtration, using dry receiver, and collect 40–50 mL. As filtering aids, use Celite with Pyrex glass filters and asbestos with Hirsch-type funnel and suction.

Polarize liq. in 10 cm tube, taking 2 sets of 10 readings each. (Av. of 2 sets should agree within 0.006°.)

$$\% \text{ Starch} = 100 \times R \times 100 / 1 \times 203 \times W = 49 \times R / W,$$

where  $R$  is observed angular rotation and  $W$  is wt sample; 203 is arbitrarily taken as specific rotation for all starches. If 200 mm tube and saccharimeter are used, 2 g sample weighed, and mixt. dild to 100 mL;  $^{\circ}\text{S} \times 4.2586 = \% \text{ starch}$ .

#### 14.033 Vitamins in Enriched Flours

See Chapter 43.

#### Chlorine in Fat of Flour

##### 14.034 Qualitative Test (Chlorine-Bleached Flours) Official Final Action

Ext 30 g flour with 50 mL pet ether and let solv. evap. (Small amt of oil remains.) Heat piece of Cu wire in colorless gas flame until it is black and no longer colors flame green. Dip hot end of wire into oil and again bring into flame. If Cl or Br has been used as bleaching agent, green or blue coloration is produced.

##### Quantitative Method (20)—Official Final Action

#### 14.035

##### Extraction of Fat

(Caution: See 51.011(a) and 51.073.)

Weigh 500 g flour into 2 L flask. Add 700 mL pet ether and shake at 5 min intervals 30 min. Filter thru buchner, pressing flour to obtain as much solv. as practicable. Transfer pet ether ext to large beaker and evap. on steam bath to ca 10 mL. Filter into container thru small funnel contg pledget of cotton packed firmly in stem. (Filtrate must be clear and free from flour.)

#### 14.036

##### Determination

Heat ca 90 mL porcelain crucible contg 10 g *fusion mixt.* (138 g  $\text{K}_2\text{CO}_3$ , 106 g  $\text{Na}_2\text{CO}_3$ , and 75 g  $\text{powd KNO}_3$ ) 30 min in 100° oven; dry in desiccator and weigh. Transfer filtered 10 mL pet ether ext to crucible, using pet ether for rinsing. Evap. pet ether on steam bath and dry fat in 100° oven 30 min. Cool, and det. wt fat by difference. Add 5 g more fusion mixt. to crucible and spread evenly. Ignite to white ash in furnace at 525° (ca 1 hr) and cool.

Add 25 mL hot  $\text{H}_2\text{O}$  to mixt. and transfer with small amt of hot  $\text{H}_2\text{O}$  to 200 mL tall beaker or beaker-flask. Cautiously add  $\text{HNO}_3$  until soln is slightly acid to litmus paper. Add 25 mL more  $\text{HNO}_3$ . Add 5 mL 0.3*N*  $\text{AgNO}_3$ . Boil 5 min in hood and cool to room temp. Filter thru 9 cm Whatman No. 1 paper, or similar Cl-free paper. Use 1%  $\text{HNO}_3$  soln for rinsing. Digest as in 3.076, par 3, beginning "Place paper and contents in Kjeldahl flask . . ." After digestion use 175 mL  $\text{H}_2\text{O}$ . Det. blank on reagents. Report Cl as mg/g fat.

##### Nitrite Nitrogen (27)—Official Final Action

#### 14.037

##### Reagents

(a) *Sulfanilic acid soln.*—Dissolve 0.5 g sulfanilic acid in 150 mL  $\text{HOAc}$  (1+4), warming slightly if necessary.

(b) *Alpha-naphthylamine hydrochloride soln.*—Dissolve, by heating, 0.2 g of the salt in 150 mL  $\text{HOAc}$  (1+4). (Caution: See 51.085.)

(c) *Nitrite std soln.*—Dissolve 0.1097 g dry  $\text{AgNO}_2$  in ca 20 mL hot  $\text{H}_2\text{O}$ , add 0.10 g  $\text{NaCl}$ , shake until  $\text{AgCl}$  flocculates, and dil. to 1 L. Draw off 10 mL clear soln and dil. to 1 L; 1 mL = 0.0001 mg N. Prep. just before use.

Prep.  $\text{AgNO}_2$  as follows: To cold soln of ca 2 g  $\text{NaNO}_2$  or  $\text{KNO}_2$  in 50 mL  $\text{H}_2\text{O}$ , add soln of  $\text{AgNO}_3$  as long as ppt forms. Decant liq. and thoroly wash ppt with cold  $\text{H}_2\text{O}$ . Crystallize from boiling  $\text{H}_2\text{O}$  and dry crystals in dark at room temp. (preferably in vac.).

#### 14.038

##### Determination

Select series of 100 mL vol. flasks of uniform dimensions and color (125 mL erlenmeyers can be used). Place 2 g untreated (nitrite-free) flour in each flask. To flasks add 0, 5, 10, 15, 20, 25, 30, and 35 mL std nitrite soln, resp., and dil. with  $\text{H}_2\text{O}$  to make 80 mL. Shake while adding std soln and  $\text{H}_2\text{O}$  to moisten and disperse flour before mixt. becomes too dil.

Add 2 g flour sample to similar flask, and add 80 mL  $\text{H}_2\text{O}$ . Place flasks in  $\text{H}_2\text{O}$  bath at 40° and digest  $\geq 15$  min. Add 2 mL sulfanilic acid soln from Mohr pipet to each flask in succession, mix well, and add 2 mL  $\alpha$ -naphthylamine.HCl soln. Continue digestion at 40° for 20 min from time of addn to last flask. Shake samples occasionally during first 10 min and let flour settle during last 10 min.

Remove from bath without disturbing settled flour. Compare unknown with series of stds and est. closest match. Multiply mL std nitrite soln in flask by 0.05 to obtain ppm N (e.g., unknown may be between 30 and 35 mL, ca 32 mL; or  $32 \times 0.05 = 1.6$  ppm N).

##### 14.039 Benzoyl Peroxide Bleach (Benzoic Acid) (22) Official Final Action

(Caution: See 51.018.)

Place 50 g flour in (preferably) 500 mL g-s erlenmeyer, and add 30–40 glass beads (ca 6 mm diam.), 0.1 g *powd Fe*, and 100 mL ether. Let stand few min, shake with rotary motion, and slowly (preferably dropwise) add 2.5 mL  $\text{HCl}$  from Mohr pipet. Let stand ca 30 min, rinse down sides with small amt of ether, and let stand overnight. Shake well with rotary motion, let flour settle few min, and decant thru 100 mm buchner, fitted with paper moistened with ether, into 500 mL suction flask. Add 50 mL ether, shake, and let settle few min. Decant as before, repeat twice more, and after last addn, transfer whole contents to filter.

Transfer ether thru large funnel into 250 mL separator, add 20 mL 5%  $\text{NaHCO}_3$  soln, mix without too much vigorous shaking, and drain clear lower layer into 125 mL erlenmeyer. Repeat with one more 20 mL portion and two 10 mL portions  $\text{NaHCO}_3$  soln. To this soln add 0.3 g *Nuchar W*, shake, and filter (11 cm S&S 589 white ribbon, or equiv.) into 200 mL erlenmeyer. Wash flask and filter with 20–25 mL  $\text{H}_2\text{O}$ , using fine stream from wash bottle. Add 2.0 mL  $\text{H}_2\text{SO}_4$  (1+1) dropwise to avoid foaming out of flask and gently swirl contents to reduce foaming. (Soln should be definitely acid to litmus paper.)

Transfer to 125 mL separator, rinse flask with 12 mL ether, and add to separator. Shake gently, frequently releasing pressure. (During first extn with ether, it is preferable to release pressure after each shake to avoid possible loss.) Repeat with 2 more 12 mL ether extns. Rinse flask each time with ether. After each extn drain aq. soln into same 200 mL erlenmeyer and transfer ether to ca 50 mL Pyrex test tube (25  $\times$  150 mm). Add 2 mL 10%  $\text{NaOH}$  soln, hold top of tube firmly against palm of hand, and shake vigorously. Insert piece of *Cu wire* (1 mm diam.

× 200 mm) into tube, and evap. ether very slowly on steam bath. Remove wire, place tubes in beaker of boiling H<sub>2</sub>O, and evap. nearly to dryness. Slowly add up to 0.5 mL 30% H<sub>2</sub>O<sub>2</sub>, followed by another 0.5 mL as soon as foam permits. (Min. frothing is desirable to permit better contact for nitration.) Break crust or film that forms before complete dryness by tapping tube against hands as evapn proceeds. Continue evapn to absolute dryness. (Introduction of gentle air current into tube hastens evapn.)

From Mohr pipet, add 4 mL mixt. of H<sub>2</sub>SO<sub>4</sub> and fuming HNO<sub>3</sub> (1+1), taking care that it washes down sides of tube, and heat 20 min in gently boiling H<sub>2</sub>O bath. Place slender glass rod in test tube, and occasionally rotate or rub rod against sides of tube to ensure contact with nitrating mixt. Immediately cool under tap to below room temp. and add 6 mL H<sub>2</sub>O while keeping tube cool. Then slowly add 5 mL NH<sub>4</sub>OH from Mohr pipet with continuous shaking under tap to keep soln cool. Add 10 mL addnl NH<sub>4</sub>OH, keeping soln cool. Add 2 mL 6% H<sub>2</sub>NOH.HCl soln, stir, and place in 65° H<sub>2</sub>O bath 5–6 min, stirring occasionally. (Initially temp. of bath should be few degrees above 65° to compensate for cold tubes.) Cool to room temp. under tap, filter immediately thru folded paper into similar tube, and observe color of filtrate. Red or definite pink indicates presence of benzoic acid.

Transfer this soln (within 30 min) to 5 cm (2") glass cell and read in photometer, using No. 51 filter, or spectrophtr set at 510 nm. Prep. std curve by placing in test tubes 0.0, 0.4, 0.8, 1.0, and 1.2 mg benzoic acid in acetone soln (0.5 mg/mL). Add 2 mL 10% NaOH soln, shake to mix well, and proceed as in par. 3, beginning "... place tubes in beaker of boiling H<sub>2</sub>O, ..." Report as ppm benzoic acid.

#### Bromates and Iodates in White and Whole Wheat Flour (23)—Official Final Action

##### 14.040 Qualitative Test for Bromates and Iodates

Cover bottom of white pan (ca 150 sq in.) with reagent prepd by mixing equal vols HCl (1+7) and 1% KI soln. Distribute ca 4 g flour evenly over liq. by sifting thru No. 60 sieve. Alternatively, sift flour over surface of dry pan and spray mixed reagent onto flour from glass atomizer until all particles are wetted. Black specks or purple spots not observed before the reagent was added indicate presence of bromate or iodate.

##### 14.041 Qualitative Test for Iodates

(a) *Applicable to 10 ppm or more.*—Distribute ca 1 g flour evenly over bottom of petri dish and completely cover with freshly prepd mixt. of 1 vol. 1% KSCN to 4 vols HCl (1+32). Break up any lumps with stirring rod and observe with dish on white surface. Interpret results as in 14.040.

(b) *Applicable to 1 ppm or more.*—Proceed as in 14.040 but use acid-KSCN reagent, (a).

#### Quantitative Method for Bromates (23)

(Applicable in absence of iodates)

##### 14.042

##### Reagents

(a) *Zinc sulfate soln.*—Dissolve 20 g ZnSO<sub>4</sub>·7H<sub>2</sub>O in 800 mL H<sub>2</sub>O and dil. to 1 L.

(b) *Sodium hydroxide std soln.*—0.4N. Dissolve 17 g NaOH in 1 L H<sub>2</sub>O. Titr. against std acid and adjust to 0.4±0.01N.

(c) *Sodium hydroxide std soln.*—0.5N. Dissolve 21 g NaOH in 1 L H<sub>2</sub>O. Titr. against std acid and adjust to 0.5±0.01N.

(d) *Dilute sulfuric acid.*—Approx. 4N. Add 112 mL H<sub>2</sub>SO<sub>4</sub> to 800 mL H<sub>2</sub>O. Cool, and dil. to 1 L.

(e) *Potassium iodide soln.*—Dissolve 25 g KI in 30 mL H<sub>2</sub>O and dil. to 50 mL. Store in amber bottle in cool place. Discard soln showing yellow (free I).

(f) *Ammonium molybdate soln.*—Dissolve 3 g (NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub>·4H<sub>2</sub>O in 80 mL H<sub>2</sub>O and dil. to 100 mL.

(g) *Potassium bromate std solns.*—(1) *Stock soln.*—5 mg/mL. Dissolve 5.000 g KBrO<sub>3</sub> (dried 1 hr at 110°) in ca 800 mL H<sub>2</sub>O and dil. to 1 L. (2) *Working soln.*—0.25 mg/mL. Dil. 25 mL stock soln to 500 mL.

(h) *Potassium iodate std solns.*—(1) *Stock soln.*—0.0898N. Dissolve 3.204 g KIO<sub>3</sub> (dried 1 hr at 110°) in ca 800 mL H<sub>2</sub>O and dil. to 1 L. (2) *Working soln.*—0.00359N. Dil. 10 mL stock soln to 250 mL. Prep. fresh daily.

(i) *Sodium thiosulfate std solns.*—(1) *Stock soln.*—Dissolve 22.5 g Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O and 0.06 g anhyd. Na<sub>2</sub>CO<sub>3</sub> in 800 mL H<sub>2</sub>O, and dil. to 1 L. Dil. 10 mL to 250 mL. Transfer 5 mL dild soln to 200 mL erlenmeyer. Add 100 mL H<sub>2</sub>O, 10 mL dil. H<sub>2</sub>SO<sub>4</sub>, and 1 mL KI soln. Add 5 mL freshly prepd starch soln, 2.144(b), and titr. with 0.00359N KIO<sub>3</sub> from 10 mL buret graduated in 0.05 mL. Adjust stock Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln so that 10 to 250 diln is 0.00359N. Store stock soln in amber bottle in cool place.

(2) *Sodium thiosulfate working soln.*—0.00359N. Dil. 10 mL stock soln to 250 mL. Prep. fresh daily and check titer at least monthly. 1 mL = 0.1 mg KBrO<sub>3</sub>.

##### 14.043

##### Determination

Quant. transfer 200 mL ZnSO<sub>4</sub> soln to 600 or 800 mL beaker and stir with speed-controlled, motor-driven glass stirrer. (Enough agitation to disperse flour is provided by vortex ca 40 mm deep which does not extend to bottom of beaker.) Transfer 50±0.1 g sample to stirred soln in 2–5 g portions. Continue stirring ca 5 min, or until all dry flour on surface is uniformly dispersed in liq. While stirring, add 50 mL 0.4N NaOH from pipet. Decrease speed of stirrer and stir ca 5 min. Filter or centr., clarifying supernate by filtration, if necessary (24 cm Whatman No. 12 folded paper, or equiv., is satisfactory).

Transfer 50 mL of this sample soln to 200 mL erlenmeyer. If smaller aliquot is taken, dil. to ca 50 mL with H<sub>2</sub>O. Add 10 mL 4N H<sub>2</sub>SO<sub>4</sub>, 1 mL KI soln, 1 drop NH<sub>4</sub> molybdate soln, and 50 mL H<sub>2</sub>O. While stirring, add 5–10 mL 0.00359N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> (an excess). Add 5 mL freshly prepd starch soln, 2.144(b), and titr. excess Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> with 0.00359N KIO<sub>3</sub>. (Use 10 mL buret graduated in 0.05 mL for std solns. End point is best observed straight down.) As end point approaches, add KIO<sub>3</sub> soln slowly, 1 or 2 drops at time, swirling and viewing flask after placing it on white surface after each addn. Take first reddish or purple tinge as end point; then add several more drops to confirm. Add addnl 1 mL Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, and again titr. to addnl end point. Average the 2 differences between amts of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln added and KIO<sub>3</sub> used in titrns; ppm KBrO<sub>3</sub> = 10 × (mL 0.00359N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> – mL 0.00359N KIO<sub>3</sub>). Correct results by recovery factor detd as below.

##### 14.044

##### Recovery Factor

Dil. known vol. (x mL), >3 mL but <10 mL, of std KBrO<sub>3</sub> soln to 250 mL. Using 50 mL aliquot, proceed as in second par. of detn.

"Added bromate" in ppm = 10 × (mL 0.00359N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> – mL 0.00359N KIO<sub>3</sub>).

Suspend 50 g portions nonbromated flour in 2 sep. 200 mL portions ZnSO<sub>4</sub> soln by stirring as above. To 1 (blank) suspension, add 10 mL H<sub>2</sub>O; to other (recovery) suspension, add x mL std KBrO<sub>3</sub> soln and (10 – x) mL H<sub>2</sub>O. Continue as above, except add 40 mL 0.5N NaOH from pipet with continuous stirring. Use 5 mL std Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> for "blank" and 10 mL for "recovery." Deduct blank value, if any, from value of KBrO<sub>3</sub> found in "recovery"

detn and multiply result by 10 to obtain ppm "recovered bromate."

Recovery factor = added bromate/recovered bromate.

#### 14.045 Pigments in Flour (24)—Official Final Action

Place 10 g flour in 125 mL g-s flask and from pipet add 50 mL  $H_2O$ -satd *n*-BuOH. Stopper flask tightly, shake well 1 min, and let stand 15 min protected from sunlight. Again shake well and filter thru 12.5 cm folded Whatman No.1 paper, collecting filtrate in 50 mL erlenmeyer or suitable container. Fill 1 cm cell with flour ext and duplicate cell with corresponding solv. Read *A* at 435.8 nm with spectrophtr. From av. of 3 readings, calc. pigment as carotene in ppm from std curve, or in absence of std carotene, from following formula:

$$C = 5.0 \times A/bK = 30.1 \times A,$$

where *C* = pigment as carotene in ppm; *b* = cell thickness (cm); and *K* = 0.16632 (*a* (mg/L) for carotene at 435.8 nm in  $H_2O$ -satd *n*-BuOH in 1 cm cell).

**Caution:** Use strictly clean cells and filter thru paper the  $H_2O$ -satd *n*-BuOH used as blank.

#### Diastatic Activity of Flour (25)—Official Final Action

##### 14.046

##### Reagent

**Acetate buffer soln.**—pH 4.6–4.8. Dil. 3 mL HOAc and 4.1 g anhyd. NaOAc to 1 L with  $H_2O$ .

##### 14.047

##### Determination

(Total maltose after diastasis 1 hr)

Place 5 g flour and teaspoonful ignited *quartz sand* in 100 or 125 mL erlenmeyer, and mix by rotating flask. Add 46 mL acetate buffer soln, and again mix by rotating flask until all flour is suspended. Bring flask and all ingredients *individually* to 30° before mixing. Digest 1 hr at 30°, preferably in temp.-controlled  $H_2O$  bath, rotating flask every 15 min. After 1 hr add 2 mL  $H_2SO_4$  (3.58±0.05*N*, ca 1+9), and mix thoroly. Add 2 mL 12%  $Na_2WO_4 \cdot 2H_2O$  soln, mix, and let stand 1–2 min. Filter thru paper (Whatman No. 4, or equiv.), discarding first 8 or 10 drops. Proceed as in 14.025(a).

These operations may be used with all ordinary flours whose values for mg maltose produced by 10 g flour in 1 hr seldom, if ever, exceed 350. For material giving higher values, such as products from malted or sprouted grain, use smaller portions of ext, *i.e.*, 1, 2, or 3 mL instead of 5 mL. In such cases, however, add enough  $H_2O$  to make up difference, and use appropriate factor to convert results into mg maltose/10 g flour. If material in test tubes is colorless instead of yellow after treatment in boiling  $H_2O$  bath and does not turn blue upon addn of KI, there is too much maltose to reduce all  $K_3Fe(CN)_6$ , and detn must be repeated with smaller amt of ext.

##### 14.048

##### Blank Determination

Blank detn to indicate amt of reducing sugar originally present in the flour—value for which presumably should be deducted from total maltose value after 1 hr diastasis—has been generally regarded as essential step in estn of flour diastatic activity. This operation ordinarily is unnecessary when dealing with flour milled from *sound* wheat, because amt of reducing sugars originally present as such is so small and so nearly const that it may be disregarded for all practical purposes. Blank detn may therefore be omitted in routine testing. It need be used only when there is doubt as to soundness of the wheat, or where there is known to have been appreciable amt of frosted, sprouted,

heat-damaged, or otherwise unsound kernels in wheat from which flour was milled.

If blank detn is desired, proceed as in 14.024.

#### Alpha-Amylase

#### AACC Falling Number (FN) Determination Method (26)

##### Official First Action

(Applicable to both meal and flour of wheat, rye, barley, and other grains, and malted cereals. Not applicable to detn of  $\alpha$ -amylase activity from fungal sources.)

##### 14.049

##### Principle

$\alpha$ -Amylase liquefies starch gel. Activity of enzyme is measured by falling number (FN), defined as time in sec required to stir and let stirrer fall measured distance thru hot aq. flour gel undergoing liquefaction.

##### 14.050

##### Apparatus

(a) **FN apparatus.**—Available from Falling Number AB, Box 32072, S-12611, Stockholm, Sweden. Specify test tube tolerances: id ±0.2 mm, od ±0.3 mm, length ±0.3 mm. Check wt of tubes, and use those that agree most closely with mean value.

(b) **Mill.**—Must produce meal with particle size distribution as follows: >500  $\mu$ m, 0–10%; >210 but <500  $\mu$ m, 25–40%; <210  $\mu$ m, 75–50%. Use either of following: Weber Pulverizer with 0.5 mm sieve (Pulverizing Machinery, Division of MikroPul Corp., 10 Chatham Rd, Summit, NJ 07901); Udy Cyclone with 0.024" sieve (UD Corporation, 1898 S Flatiron Ct, Boulder, CO 80301); or equiv.

(c) **Automatic pipet.**—Calibrated to deliver 25±0.3 mL.

(d) **Thermometer.**—NBS or equiv., calibrated in 0.1° and certified accurate to ±0.3°.

##### 14.051

##### Preparation of Sample

Grind ca 250 g grain sample in mill. Moisture content of grain should be within range of ca 8–16%. Add  $H_2O$  to grain with <8% moisture, and air- or vac.-dry grain with >16% moisture.

##### 14.052

##### Temperature Adjustment of FN Apparatus

Const temperature  $H_2O$  bath of FN apparatus must be maintained at 100.0°. Prep. as follows: Fill reservoir with  $H_2O$  to  $H_2O$ -level control fixed at 2.5 cm below cover. Place rubber stopper contg thermometer in tube well and let remain until temp. is const. If bath temp. is between 98.0° and 99.8°, adjust it to 100.0° with amt ethylene glycol or glycerol indicated in Table 14.02.

If bath temp. is <98.0°, do not attempt temp. readjustment because of danger of boiling out contents of FN tube. Instead,

**Table 14.02 Ethylene Glycol or Glycerol Required to Adjust Constant Temperature Water Bath to 100.0°**

Temp Elevation, °C	Amt to be Added, % by Vol.	
	Ethylene Glycol	Glycerol
0.2	1.9	2.5
0.4	3.9	4.9
0.6	5.8	7.4
0.8	7.8	9.8
1.0	9.7	12.3
1.2	11.3	14.2
1.4	12.9	16.1
1.6	14.4	18.1
1.8	16.0	20.0
2.0	17.6	21.9

det. FN at observed bp, e.g., 96.0°, as in 14.053. Then adjust temp. to 97.5° by adding 13.6% ethylene glycol and det. FN again. Plot both values against temp. on graph paper and extrapolate to 100.0°. Read FN from graph at this point.

If bath temp. is >100.2°, add 0.1% isopropanol to H<sub>2</sub>O for each 0.1° of excess temp. above 100.0°. Observe thermometer-immersion point, and if stem correction is applicable, use following formula:

$$\text{Stem correction} = K \times n \times (T - t),$$

where  $K = 0.00016$  for Hg,  $n$  = no. of degrees Hg column above stoppered H<sub>2</sub>O bath,  $T$  = bath temp., and  $t$  = Hg temp. above stopper (room temp.).

#### 14.053

#### Determination

Weigh 7.00 g (or appropriate wt sample calcd to 14% H<sub>2</sub>O basis =  $7.00(100 - 14)/(100 - x)$ , where  $x$  = actual % H<sub>2</sub>O) flour or ground meal into dry FN tube and tip to 45° angle. Add 25 mL H<sub>2</sub>O with automatic pipet. Insert rubber stopper and shake in upright position 10 times (up and down), making sure all flour is suspended by upending. Scrape down upper part of tube with viscometer-stirrer. Remove stopper from bath well. Simultaneously start timer; place tube in bath and lock into position, taking ≤5 sec. Stir sample with viscometer-stirrer at rate of 2 strokes/sec (down and up is 1 stroke) until clock reaches 60 sec, for total of 110 strokes. Stop with stirrer in up position. If automatic timer is used, set wire against stirrer so that buzzer and shut-off mechanism will be activated at conclusion of test. Let stirrer drop by its own wt. Stop buzzer by pushing small top knob, which controls contact wire, counterclockwise. Record time in sec (stirring plus dropping time). Quickly remove test tube from bath and insert stopper or another empty test tube to prevent H<sub>2</sub>O evapn. Hold tube under running H<sub>2</sub>O and remove viscometer-stirrer. Remove starch gel from tube by means of spatula with extended handle. Clean viscometer-stirrer with test-tube brush. Use air jet to remove any remaining gel and H<sub>2</sub>O from orifice.

FN (14% moisture basis) =  $FN_{as} \times (100 - 14)/(100 - M)$ ,  
where  $M$  = % moisture in sample.

#### Proteolytic Activity of Flour and Malted Wheat Flour (27)—Official Final Action

(Applicable to slightly active materials such as patent flour or to dild exts of active proteolytic prepsns)

#### 14.054

#### Reagents

(a) *Buffer stock soln.*—pH 4.7. Dil. 120 mL HOAc and 164 g anhyd. NaOAc to 1 L with H<sub>2</sub>O. Dil. with 20 vols H<sub>2</sub>O before using.

(b) *Bacto-hemoglobin substrate.*—Obtainable from Difco Laboratories.

(c) *Trichloroacetic acid (TCA) soln.*—Dissolve 180 g trichloroacetic acid in 320 mL H<sub>2</sub>O. (Caution: See 51.082.)

#### 14.055

#### Determination

(a) *Preparation of enzyme solns.*—For slightly active materials such as flour, weigh as much as 10 g directly into digestion flasks. For active enzyme prepsns, prep. ext or suspension in dild buffer, 14.054(a), immediately before digestion. (Amt of ext or dilns thereof used in digestion mixt. may vary up to 2 mL; appropriate activation technics may be applied to enzyme exts.)

(b) *Digestion procedure.*—Weigh 2.50 g (H<sub>2</sub>O-free basis) Bacto-hemoglobin into each of two 125 mL erlenmeyers, add ca 5 g or 1 teaspoon fine pumice and flour sample, (a), to each flask, and agitate mixt. by rotation until flour and substrate are

intimately mixed. Then to each flask add 50 mL dild acetate buffer soln, previously warmed to 40±0.1° in temp.-controlled bath, and agitate mixt. to suspend uniformly. Place tightly stoppered flasks in 40° bath and agitate either continuously or at 1 hr intervals.

Add 10 mL portion TCA soln, (c), to one flask after 15 min digestion and to second flask after 5.25 hr digestion. Shake each flask, using 25 vigorous horizontal movements, and keep flasks in bath at 40° exactly 30 min. Centrf. suspension 5 min at 1800 rpm and filter. (Some materials such as flour may remain turbid after final filtration; clear by boiling centrfd digestion mixt. few sec before final filtration. Replace liq. lost thru evapn by adding H<sub>2</sub>O.) Pipet duplicate 10 mL aliquots directly into Kjeldahl flasks and det. sol. N.

Follow essentially same operations in detg enzyme activity of an ext. In place of solid material, use total of 2 mL ext or ext plus dild buffer soln. After 0 time and 5 hr digestion periods, add 10 mL aliquot of TCA soln, (c), to each flask. Mix thoroly, keep in H<sub>2</sub>O bath exactly 30 min, and filter without centrfg. Analyze 10 mL aliquots for sol. N.

(c) *Determination of soluble nitrogen.*—Proceed as in 2.057. Use definite vol. H<sub>2</sub>O (350 mL) to dil. cooled digest and add in such way as to wash down all TCA that has condensed in neck of flask during digestion. Also add NaOH soln, 2.055(f) (1.5 times usual amt), so as to rinse neck of flask. After distn, back-titr. unneutd std acid with stdzd ca 0.07N NaOH.

(d) *Expression of proteolytic activity.*—Proteolytic activity is measured by difference in back-titrn vols for 15 min or 0 time digestions and corresponding long-time digestion, calcd as mL 0.0714N NaOH. Transform proteolytic activity detd for 10 mL aliquot to 3/2 power. Multiply this value by 6 (total final vol. of digest/10 mL aliquot) and by 1000/mL enzyme source. This value is activity expressed in hemoglobin units (HU)/g enzyme prepn (Arch. Biochem. 32, 200(1951)).

(e) *Curve method.*—Use 3 to 5 levels of flour or dilns of active enzyme prepsns, and digest and det. sol. N as in (b) and (c). Plot mg sample (for 60 mL final vols of digest) against mL 0.0714N NaOH titrn difference (= mg increase in sol. N) for the 10 mL aliquots. From smooth curve obtained, read mg sample equiv. to titrn difference of 5.00 mL. Raise 5.00 to 3/2 power (= 11.18). Multiply this value by 6 and by 1000/mg enzyme source to obtain activity as HU/g.

(f) *Std curve method.*—Use 5 dilns of active enzyme prepn to be used as std, and digest and det. sol. N as in (b) and (c). Plot curve and calc. HU/g as in (e) for this std sample. For each unknown sample, using single sample size, digest and det. sol. N as in (b) and (c). From std curve, det. mg std sample to give titrn difference found for unknown sample. Multiply proteolytic value HU/g for std by ratio obtained by dividing wt std sample by wt unknown sample. Result is activity of unknown as HU/g.

*Notes:* (1) Careful washing down of TCA from neck of digestion flasks is mandatory. If not neutzd, TCA steam distills.

(2) More reproducible results will be obtained if Kjeldahl detns are completed without delay between digestion and distn.

(3) If other than 10 mL aliquots are analyzed for sol. N, convert results to 10 mL aliquot basis before transforming to 3/2 power. If titrn difference, using 10 mL aliquot, is >10 mL 0.0714N NaOH, reanalyze, using smaller amt of enzyme. For most precise results, titrn difference should be 4.0–6.0 mL 0.0714N NaOH.

(4) For each lot of hemoglobin, adjust pH of stock buffer, if necessary, so that pH of mixt. of 50 mL dild buffer, 2.5 g hemoglobin, and ca 5 g pumice will be 4.70±0.05. This pH for buffer substrate mixt. is critical for accuracy of method.

(5) Accurate results are obtainable only when titrn difference for detn is close to 5.00 mL 0.0714N NaOH. For single point method, restricted range of titrn difference between 4.0 and 6.0 is recommended, but even within extremes of this range,

variations in sol. N for different wt enzyme samples will cause differences of several % in calcd HU/g values.

(6) Curve methods for detn of proteolytic activity have advantage of using exactly 5.00 mL titrn difference (5.00 mg increase in sol. N) as ideal ref. point. They permit working in range 3.0–8.0 mL titrn difference.

(7) Std curve method using std sample and unknowns each at 1 level is especially useful where routine assays on large number of samples are required. Advantage of using std sample is that it affords automatic check on minor day-to-day variations in technic.

(8) It is convenient for routine analyses to use 0.0714N NaOH for back-titrn, since 1 mL titrn difference = 1 mL increase in sol. N.

#### Apparent Viscosity of Acidulated Flour-Water Suspension Official Final Action

By MacMichael Viscosimeter (28)

##### 14.056 Adjustment of Machine

- (a) Use No. 30 MacMichael viscosimeter wire.
- (b) Have diam. of disk plunger  $2.375 \pm 0.01$ ".
- (c) Adjust clearance between bottom of disk and inner surface of bottom of bowl to  $0.25 \pm 0.005$ ". Carefully check clearance with depth gage reading in 0.001".
- (d) Use viscosimeter bowl with ca 7 cm diam. (depth of bowl will vary according to age of machine).
- (e) Adjust regulating device to permit speed of exactly 12 rpm and check carefully and frequently with stop-watch, because as motor warms up, machine tends to increase its speed.
- (f) Adjust machine and keep it level, and when bob is placed see that it is riding freely and not touching sides of guide.
- (g) Adjust dial so that when it comes to rest, pointer is on 0 mark.

##### 14.057 Preparation of Lactic Acid

To concd lactic acid add ca proportion of H<sub>2</sub>O to give slightly >1N soln. Reflux 3 hr, cool, and adjust to 1N by adding H<sub>2</sub>O. Or proceed as follows: Use enough concd lactic acid to prep. soln ca 0.85N when stdzd with 0.1N NaOH. Transfer to erlenmeyer fitted with air condenser to prevent undue evapn of H<sub>2</sub>O, and heat 24 hr at 80° (soln will have increased in strength to ca 1.18N). Adjust to exactly 1N with H<sub>2</sub>O.

##### 14.058 Preparation of Flour-Water Suspension

In clean, dry, 500 mL erlenmeyer, place 20 g flour (15% moisture basis) and add 100 mL H<sub>2</sub>O at 30°. Close with rubber stopper and shake vigorously 1 min. Place flask in const temp. cabinet or H<sub>2</sub>O bath 1 hr at 30°, shaking ca 10 times every 15 min. Remove flask, add 3 or 4 drops *capryl alcohol*, shake 10 times to remove any foam that may be present, and pour suspension into bowl of viscosimeter.

##### 14.059 Determination

After pouring suspension into viscosimeter bowl, make sure bowl is flush on its supports. Start machine, but before placing bob or disk in place, stir soln with bob 25 times to ensure uniform suspension. Place wire of bob in holder and take reading after damping swing of dial by placing a finger on indicator pointer and then gradually touching swinging dial. Make second reading after adding 1 mL 1N lactic acid, and likewise third and following readings after adding 2 mL increments 1N lactic acid. Do not stop motor between readings. After or during addn of lactic acid, stir suspension 25 times by up-and-down motion of bob. Suspend bob by the wire and take reading. Det. max. apparent viscosity of the acidulated flour-H<sub>2</sub>O suspension by

plotting apparent viscosity readings against vol. acid added. Usually total of 7 mL 1N lactic acid is enough for max. reading, but 2 mL increments should be added continuously until apparent viscosity no longer increases.

#### Soybean Flour in Uncooked Cereal Products (29)

##### 14.060 Qualitative Test—Official Final Action

Place ca 0.5 g sample in small test tube contg strip of red litmus paper partly immersed in 5 mL 2% *urea soln*. Mix, stopper tube, and heat 3 hr at 40°. If soybean flour is present in more than traces, litmus paper turns blue. (Bromothymol blue may also be used as indicator; it likewise turns blue if soybean flour is present.)

##### 14.061 Uric Acid in Flour—Official Final Action

##### 14.067 Crude Fat or Ether Extract

See 7.056.

#### Protein (31)

##### 14.068 Kjeldahl Method

See 2.057. Protein =  $N \times F$ , where  $F = 5.83$  for barley, millet, oats, rye, and whole kernel wheat; 6.25, corn and sorghum; 5.95, rice; 6.31, wheat bran; 5.80, wheat embryo; 5.70, wheat endosperm; 5.71, soybeans; 6.25, beans (adzuki, jack, lima, mung, navy, and velvet); 5.30, castor beans; 5.30, seeds (cantaloupe, cotton, flax, hemp, pumpkin, sesame, and sunflower).

##### 14.069 Automated Method—Official First Action

See 7.021–7.024.

#### Fat Acidity

##### 14.070

##### Reagents

(a) *Benzene-alcohol-phenolphthalein soln.*—0.02%. To 1 L benzene add 1 L alcohol and 0.4 g phthln.

(b) *Alcohol-phenolphthalein soln.*—0.04%. To 1 L alcohol add 0.4 g phthln.

\* Unless otherwise indicated.

(c) *Potassium hydroxide std soln.*—0.0178*N*, carbonate-free. 1 mL = 1 mg KOH.

**14.071****Apparatus**

- (a) *Grain mill.*—Suitable for grinding small samples.  
 (b) *Fat extraction device.*—Soxhlet or other suitable type. (Durable paper thimbles or Alundum RA-360 thimbles are suitable for extrn.)

**14.072 Method I (14)**

(Caution: See 51.009, 51.011(a), and 51.073.)

Obtain representative sample of ca 50 g grain (corn, 200 g) by hand quartering or by use of mech. sampling device. Preferably grind sample so that  $\geq 90\%$  will pass No. 40 sieve (somewhat coarser grind will not materially affect results). If sample is too moist to grind readily, dry at temp. of ca 100° just long enough to remove excess moisture.

Ext  $10 \pm 0.01$  g ground sample with pet ether ca 16 hr in extractor. Start extrn as soon as possible after grinding and never let ground sample remain overnight. Completely evap. solv. from ext on steam bath. Dissolve residue in extrn flask with 50 mL benzene-alcohol-phthln soln and titr. with std KOH soln to distinct pink, or in case of yellow soln to orange-pink. If emulsion forms during titrn, dispel by adding second 50 mL portion of benzene-alcohol-phthln soln. End point should match color of soln made by adding 2.5 mL 0.01%  $KMnO_4$  soln to 50 mL  $K_2Cr_2O_7$  soln of proper strength to match color of original soln being titrd. (Add 0.5%  $K_2Cr_2O_7$  soln dropwise to 50 mL  $H_2O$  until color matches. Then add 2.5 mL 0.01%  $KMnO_4$  soln.)

Make blank titrn on 50 mL benzene-alcohol-phthln soln and subtract this value from titrn value of sample. If addnl 50 mL portion benzene-alcohol-phthln soln was added, double blank titrn. Report fat acidity as mg KOH required to neutze free fatty acids from 100 g grain (dry basis). Fat acidity =  $10 \times (\text{titrn} - \text{blank})$ .

**14.073 Method II. Rapid Method for Corn**

(Result may be obtained in <1 hr)

Prep. sample as in 14.072. Weigh  $20 \pm 0.01$  g into 100 mL g-s flask or bottle. Add exactly 50 mL benzene, insert stopper, shake few sec to sat. air in flask with benzene vapor, momentarily loosen stopper to release pressure, and replace stopper. Shake flask 30 min in mech. shaker, or periodically by hand 45 min. Tilt flask and let meal settle at an angle  $\geq 3$  min. Carefully decant as much liq. as possible into 15 cm folded paper inserted in 8 cm glass funnel, and cover funnel with cover glass to reduce evapn. Collect exactly 25 mL filtrate in 25 mL vol. flask. Transfer this filtrate to 250 mL Florence flask. Refill vol. flask to 25 mL mark with alcohol-phthln soln and transfer to flask contg benzene ext.

Using color std prepd as in 14.072, titr. ext with std KOH soln to distinct pink in case of white corn, and to orange-pink for yellow corn. If emulsion forms during titrn, dispel by adding 25 mL each of benzene and of alcohol-phthln soln. Det. blank titrn on mixt. of 25 mL benzene and 25 mL alcohol-phthln soln. If addnl benzene and alcohol were added, double blank titrn. Report fat acidity as mg KOH required to neutze free fatty acids from 100 g corn (dry basis).

Fat acidity =  $10 \times (\text{titrn} - \text{blank})$ , calcd on dry basis.

**14.074 Vitamins in Enriched Grains**

See Chapter 43.

**Starch (32)—Official First Action**

(Applicable to grains, stock feeds, and cereals)

**14.075****Reagents**

(a) 80% *Isopropanol-salt soln.*—Dissolve 10 g NaCl in ca 150 mL  $H_2O$ , add 800 mL isopropanol (USP or reagent grade) on basis of 100% purity, and dil. to 1 L at ca 20°.

(b) *Acetate buffer, 4*M*.*—Dissolve 330 g anhyd. NaOAc in 1 L  $H_2O$ , add 240 mL (or 251 g) HOAc, cool, and dil. to 2 L.

(c) *Acetate buffer, 0.4*M*.*—pH 4.7–4.8. Dil. 4*M* acetate buffer to 0.4*M*. Check pH with pH meter.

(d) *Enzyme prepn.*—Rhozyme-S, high potency conc., low reducing sugar content (Rohm and Haas Co.). Prep. daily required vol. of 2% aq. soln.

*Note:* 25 mg enzyme prepn, Factor 4 (manufacturer's activity factor based on maltose hydrolysis), yields 99% calcd glucose from 200 mg ash-free dry matter of USP Reference Potato Starch at pH 4.7 after 6 hr at 50°. Use 100 mg enzyme to hydrolyze  $\leq 400$  mg total available carbohydrate. Thus at least twice necessary amt is used. This amt will completely hydrolyze sucrose, maltose, lactose, and cellobiose, if present.

(e) 2-*Octanol (capryl alcohol).*—Ketone-free, bp 178–180° (Eastman Kodak Co.).

(f) *Zinc sulfate soln.*—10%  $ZnSO_4 \cdot 7H_2O$ .

(g) *Ferricyanide (FeCy) reagent.*—0.04*N*. Dissolve 100 g anhyd.  $Na_2CO_3$  and 26.40 g anhyd.  $K_3Fe(CN)_6$  in  $H_2O$  and dil. to 2 L at 20°. Protect from strong light during prepn. Store in bottle completely covered with heavy Al foil or black paint. Soln is stable indefinitely at 25° when protected from light; however, prep. fresh soln every 6 months. 5 mL FeCy soln with 5 mL  $H_2O$ , 1 mL KI soln, and 5 mL  $ZnSO_4$ -HOAc soln should yield 1 equiv. to 20.0 mL 0.01*N* thiosulfate.

(h) *Potassium iodide soln.*—20 g/100 mL. Protect from strong light; keep cold when not in use. Prep. fresh after 1–2 months.

(i) *Zinc sulfate-acetic acid soln.*—60 mL HOAc and 60 g  $ZnSO_4 \cdot 7H_2O$ /L.

(j) *Sodium thiosulfate std solns.*—(1) Approx. 0.1*N*. Prep. and stdze as in 50.037–50.038. Normality decreases rapidly during first week, but thereafter remains virtually const, decreasing ca 0.0001*N*/month under usual laboratory conditions. (2) *Working soln.*—Prep. daily from (1) exactly 0.01*N* soln. Protect 0.01*N* soln from heat and strong light.

(k) *Starch soln.*—Suspend 10 g sol. starch in cold  $H_2O$ . Add to ca 500 mL boiling  $H_2O$ , dil. to ca 1 L with boiling  $H_2O$ , and boil several min. Keep in refrigerator. Prep. fresh soln after 1–2 months. Decant supernate as needed in titrns.

(l) *Glucose std solns.*—(1) *Stock soln.*—10 mg/mL. To 500 vol. flask transfer 5.0025 g (assume 99.95% purity) NBS Dextrose SRM No. 41, dried in vac. at 25–40°, add 5 mL 0.1*N* HCl, and dil. to vol. at 20°. Store in refrigerator. (2) *Working solns.*—0.5–5.0 mg glucose/5 or 10 mL. Dil. 1–10 mL aliquots stock soln to 100 or 200 mL.

**14.076****Apparatus**

(a) *Weighing funnels.*—Glass, 15 × 45 mm (similar to No. 30287-029, VWR Scientific, Inc., PO Box 3200, San Francisco, CA 94119, or No. 12803, New York Laboratory Supply Co.).

(b) *J-rods.*—Glass rods, 3 mm diam. and 300 mm long, bent and shaped at one end to fit round bottom of 25 mm diam. test tube.

(c) *Test tubes.*—Pyrex, 32 × 200 mm, calibrated at 50 and 75 mL for starch detn. Pyrex, thin-wall, 29 × 200 mm, for reducing sugars detn.

(d) *Water baths.*—Electrically heated, thermostatically controlled to  $\pm 1^\circ$ , fitted with elec. stirrer, 36 × 60 cm (14 × 24") od.

(e) *Cooling bath*.—With running H<sub>2</sub>O at ca 20°, 36 × 60 × 13 cm (14 × 24 × 5").

(f) *Spectrophotometer*.—Prism or grating, with Corex 1 cm sq cells, or equiv.

#### 14.077

#### Extraction

(Conduct blanks thru entire detn.)

Transfer 250–1000 mg sample, contg ≤400 mg starch and sol. sugars, to test tube. Use weighing funnel for <500 mg samples, letting tared funnel and sample slide to bottom of tube. Add ca 500 mg NaCl. Pipet in 35 mL isopropanol (on basis of 100% purity). Insert J-rod, mix thoroly, and let stand ca 10 min, mixing frequently to ext lipids. Add H<sub>2</sub>O to 50 mL, plus 1.5 mL to allow for vol. of weighing funnel. Let stand 60 min in H<sub>2</sub>O bath at ca 20°, mixing frequently to assure soln of sol. carbohydrates. Add ca 200 mg Celite and continue extrn 30 min (total of 90 min) at ca 20°, mixing frequently.

Decant thru 15 cm Whatman No. 54 paper; let liq. drain completely from paper. Transfer remaining solids in tube, using 80% isopropanol-NaCl soln cooled to 15–20°. Save tube and J-rod. Wash paper and contents with small vols cooled isopropanol-NaCl soln, letting contents drain after each washing. Use ca 150 mL cooled isopropanol-NaCl soln for transfer and washings. Keep funnel covered thruout. Discard filtrate and washings.

With cool H<sub>2</sub>O, transfer residue from paper to original test tube. (Quant. removal requires care and previous practice.) Remove last traces of sample by rubbing entire surface of paper several times with rubber policeman, followed by washing with fine jets of cool H<sub>2</sub>O. Finally, wash entire surface and funnel. Vol. in test tube should be ≤75 mL. (At this point analysis may be delayed 24–48 hr without significant loss of enzymatic digestibility of starch.) Store in refrigerator.

#### 14.078

#### Enzymatic Hydrolysis

Add 1–2 drops octanol; heat 60 min in H<sub>2</sub>O bath at ≥90°, mixing frequently with J-rod, especially during first 10 min. (Residues of some samples, especially those which contain much starch, may "explode" and foam over when heated >90°.) Cool and, *without delay, perform enzymatic hydrolysis*. (Storage in refrigerator overnight or longer may significantly decrease yield of reducing sugar.) Add 5 mL 0.4M acetate buffer and 5 mL enzyme soln. Incubate 6 hr at 50°, mixing frequently, especially during first 10 min.

#### 14.079

#### Clarification

Quant. transfer contents to 250 mL vol. flask. Add 10 mL ZnSO<sub>4</sub> soln, 2–3 drops phthln, and 1–2 drops octanol. While rotating flask, rapidly add 0.5N NaOH until Zn(OH)<sub>2</sub> begins to ppt, and carefully add alkali until contents are faint pink. Add 0.5N HCl drop by drop until colorless, and dil. to vol. Let stand ca 10 min, mixing frequently, and filter.

Store filtrate in refrigerator; analyze within 24 hr.

#### 14.080

#### Ferricyanide Reduction and Determination of Starch

(a) *Titrimetric method*.—Transfer 2, 3, 4, or 5 mL sample and reagent blank, from 14.079, to bottom of 29 × 200 mm test tubes, covered with small beakers or, preferably, with large glass bulbs; add H<sub>2</sub>O to *exactly* 5 mL. Add *exactly* 5 mL FeCy reagent, and mix immediately by gently rotating tube. Incubate *exactly* 30 min in H<sub>2</sub>O bath at 80±1°; cool rapidly in running H<sub>2</sub>O bath at 20–25°. (Greatest accuracy is obtained with vol. of sample soln contg 3–3.5 mg glucose and resulting in ca 50% reduction

of FeCy. Accuracy in measurement of 5 mL FeCy reagent is important, since errors are increased in detn of residual FeCy.)

If 5 mL sample soln contains <1 mg glucose, use 10 mL sample and blank soln, add 5 mL FeCy reagent, mix immediately, and proceed as before.

Add 1 mL KI soln and 5 mL ZnSO<sub>4</sub>-HOAc soln, mixing by gentle rotation after each addn. To prevent I loss, cover tubes immediately and keep covered until titrn. Let stand ≥20 min, mixing contents twice. Titri. with 0.01N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> until almost colorless, adding first few mL around sides of tube to prevent loss of I vapors. Add ca 0.5 mL starch soln; wash sides of tubes and continue titrn drop by drop until color is pure white.

(b) *Spectrophotometric method*.—To enzymatic digest, in 250 mL vol. flask, add 10 mL ZnSO<sub>4</sub> soln and 0.5N NaOH to ca pH 7.5. (Phthln interferes in detn. Det. vol. 0.5N NaOH required by titrg blank contg 5 mL 0.4M acetate buffer and 10 mL ZnSO<sub>4</sub> soln, using pH meter or titrg until red to phenol red and colorless to phthln.) Dil. to vol., mix, filter, and check pH. Transfer 2, 3, 4, 5, or 10 mL to 29 × 200 mm test tube and conduct ferricyanide reduction as in (a).

Dil. FeCy reaction mixt. to 250 mL, and det. %T at 418 nm, using 1 cm sq Corex cells.

(c) *Standardization*.—Stdze detn, using 5 mL std glucose soln contg 1–5 mg glucose or 10 mL std soln contg 1–5 mg glucose. Use 5 mL FeCy reagent in all stdzns. Using 4 detns, calc. av. mg glucose/mL FeCy reagent reduced.

(d) *Calculations*.—Calc. % reducing sugar, RS, expressed as glucose. Assume 97.5% recovery of RS, due to incomplete mobilization of starch from sample tissues, recovery from paper, hydrolysis to RS, and loss during pptn and filtration.

% Starch = 0.923 × % RS.

#### AACC Glucoamylase Method with Subsequent Measurement of Glucose with Glucose Oxidase (33) Official First Action

(Applicable to raw and cooked cereals)

#### 14.081

#### Reagents

(a) *Glucoamylase soln*.—10 mg (30 IU)/mL H<sub>2</sub>O. Purity of enzyme is critical; should be prepd from *Rhizopus delemar*. Prepn Sumizyme 3000 from Shin Nihon Chemical Co., 19-10 Showa-cho, Anjo-city, Aichi, Japan has been found satisfactory.

(b) *D-Glucose std soln*.—400 mg anhyd./L. Let stand 4 hr to complete mutarotation before use.

(c) *Acetate buffer*.—4M, pH 4.8. Dil. 120 mL HOAc and 164 g anhyd. NaOAc to 1 L with H<sub>2</sub>O.

(d) *Tris-phosphate buffer*.—pH 7.0. Dissolve 36.3 g trihydroxymethylaminomethane and 50.0 g NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O (or 45.5 g anhyd.) in 500 mL H<sub>2</sub>O. Adjust pH to 7.0 with H<sub>3</sub>PO<sub>4</sub> at 37° and dil to 1 L with H<sub>2</sub>O at 37°.

(e) *Enzyme-buffer-chromogen mixture*.—Dissolve in 100 mL tris-phosphate buffer: 30 mg glucose oxidase (Type II from *Aspergillus niger*, Sigma Chemical Co.), 3 mg peroxidase (Type I from horseradish, Sigma Chemical Co.), and 10 mg *o*-dianisidine·2HCl. Disperse *o*-dianisidine completely in small amt of buffer before adding it to enzyme-buffer mixt. Store ≤10 days at 4°. Available in prepd form from Worthington Biochemical Corp. Freehold, NJ 07728, as Glucostat special, Sigma Chemical Co., and Calbiochem.

#### 14.082

#### Determination

(For products cont d-glucose and polysaccharides derived from starch with dextrose equiv. <14, ext with 2 portions boiling 80% alcohol and 2 portions 80% alcohol at 25°. Remove alcohol completely by evapn, since alcohol inhibits glucoamylase activity.)

Grind sample to <0.5 mm (No. 40 sieve). Det. moisture. Weigh 0.5 g sample ( $\leq 1.0$  g contg  $\leq 0.5$  g starch) into dried, weighed erlenmeyer. Add 25 mL  $H_2O$  with stirring and adjust pH to 5–7, if necessary. Boil with gentle stirring 3 min and then autoclave 1 hr at 135°. (Lower autoclave pressure and temp. but  $\geq 1$  hr may be used with some starches to achieve complete gelatinization.) Remove from autoclave, cool to ca 55°, and add 2.5 mL acetate buffer and sufficient  $H_2O$  to total wt of soln of  $45 \pm 1$  g. Immerse flask in  $H_2O$  bath with shaker at optimal temp. of glucoamylase used (usually  $55 \pm 1^\circ$ ) and add 5 mL glucoamylase soln. Hydrolyze 2 hr with continuous shaking, filter thru folded paper into 250 mL vol. flask, wash quant., and dil. to vol.

Transfer 1 mL aliquots contg 20–60  $\mu$ g D-glucose to test tubes. Dil. filtrate, if necessary, to obtain this concn. Add 2 mL enzyme-buffer-chromogen mixt., shake tubes, and place in dark at  $37 \pm 1^\circ$  exactly 30 min to develop color. Stop reaction by adding 2 mL  $H_2SO_4$  (1+1) and measure  $A$  at 540 nm.

Prep. std curve from 0–60  $\mu$ g D-glucose/mL and blank. Include control of sample contg starch of known purity from source similar to material being examined.

$$\% \text{ starch} = 0.9 \times (M/10^6) \times (V_1/1) \times (250/V_0) \times (100/E) \\ \times (100/MS) = 2.25 \times (M \times V_1/V_0 \times E \times MS),$$

where  $E$  = g sample,  $M$  =  $\mu$ g D-glucose from std curve,  $V_0$  = mL aliquot from 250 mL vol.,  $MS$  = % solids in sample, and  $V_1$  = final mL if 250 mL is further dild ( $V_1 = 1$  if no further dild).

**14.083****Antioxidants**

(Applicable to corn and rice breakfast cereals)

See 20.009–20.012.

**SOYBEAN FLOUR (34)—OFFICIAL FINAL ACTION****14.084****Moisture**

Proceed as in 14.004, except use 5 g sample and dry 2 hr.

**14.085 Ash**

See 7.009.

**14.086 Nitrogen**

See 2.057.

**14.087 Crude Fiber**

See 7.065.

**Petroleum Ether Extract or Oil****14.088****Reagent**

*Petroleum ether*.—Initial boiling temp., 35–38°; dry-flask end point, 52–60°;  $\geq 95\%$  distg  $< 54^\circ$ , and  $\leq 60\%$  distg  $< 40^\circ$ ; sp gr at 60°F, 0.630–0.660; evapn residue  $\leq 0.002\%$  by wt.

**14.089****Determination**

Accurately weigh duplicate samples of 2 g full-fat or 5 g low-fat soy flour and wrap each portion in 150 mm filter paper (S&S 597, or equiv.); rewrap in second paper or papers so as to prevent escape of sample, leaving top of second paper open like thimble. Place piece of absorbent cotton in top of thimble to distribute the dropping ether. Place 25 mL pet ether in 125 mL tared flask, and ext sample 5 hr in Butt-type or similar extractor. (Ether should drop on center of thimble at rate of  $\geq 150$  drops/min, and vol. solv. should be kept ca const.) Evap. solv. until no trace remains, cool sample to room temp., and weigh. As last traces of ether are sometimes difficult to detect by odor, heat  $\geq 1$  hr to const wt.

**BREAD****14.090 Preparation of Sample—Official Final Action**

(When total solids of original loaf are not desired)

(a) *All types of bread not containing fruit (35)*.—Cut loaf, or  $\frac{1}{2}$  loaf, of bread into slices 2–3 mm thick. Spread slices on paper and let dry in warm room until sufficiently crisp and brittle to grind well in mill. Grind entire sample to pass No. 20 sieve, mix well, and keep in air-tight container.

(b) *Raisin bread*.—Proceed as in (a), except comminute by passing twice thru food chopper instead of grinder.

**14.091 Total Solids in Entire Loaf of Bread Official Final Action**

(a) *All types of bread not containing fruit (35)*.—Accurately weigh loaf of bread immediately upon receipt (X), using scales sensitive to at least 0.2 g. If impossible to weigh accurately at this time, seal sample in air-tight container and weigh accurately as soon thereafter as is practicable (X). Preserve sample in such manner that no loss of bread solids can occur whereby loss would be calcd as moisture.

Cut bread into slices 2–3 mm thick ( $\frac{1}{2}$  loaf may be used). Spread slices on paper, let dry in warm room (15–20 hr), and when apparently dry, break into fragments. If bread is not entirely crisp and brittle, let it dry longer—until it is in equilibrium with moisture of air—so that no moisture changes occur during grinding. Quant. transfer air-dried bread to scale pan and weigh accurately (Y). Grind sample to pass No. 20 sieve, mix well, and keep in air-tight container. Det. % total solids (Z) of ground sample as in 14.003 or 14.004. Calc. total solids (TS) of bread:

$$TS = (100 \times Y \times Z/100)/X, \text{ or } Y \times Z/X,$$

where X = wt loaf (or  $\frac{1}{2}$  loaf) at time of receipt; Y = wt air-dried sliced bread; and Z = % total solids in prepd ground sample.

(b) *Raisin bread and bread containing raisins and fruit*.—Proceed as in (a), except comminute by passing twice thru food chopper instead of grinder and dry air-dried sample in uncovered dish ca 16 hr at 70° under pressure  $\leq 50$  mm Hg (6.7 kPa).

**14.092 Total Solids of Air-Dried Ground Sample (35) Official Final Action**

Use 2 g prepd sample, 14.090, and proceed as in 14.003 or 14.004.

**14.093 Fat and Fat Number (36)—Official Final Action**

(Caution: See 51.011, 51.054, 51.073, and 51.086.)

Slice one loaf of bread, and let dry overnight, or until dry enough to grind. Grind bread to ca size of openings on No. 20 sieve, mix, and transfer 50 g to 600 mL beaker. Add 100 mL  $H_2O$  and mix. Add 100 mL HCl, mix, cover, and heat on steam bath 1 hr, stirring well 6 or 7 times. Cool in cold  $H_2O$  bath ( $\leq 15^\circ$ ) and stir. Add 10 g Filter-Cel, or similar absorbent, stir, and mix completely. Prep. 90 mm buchner as follows:

Place two 9 cm S&S 589 Blue Ribbon, or equiv., filter papers in funnel and apply suction. Mix 10 g Filter-Cel with 50 mL  $H_2O$  and rapidly pour mixt. into funnel. (This should make smooth, even layer of Filter-Cel over paper, without cracks or openings.) Immediately filter sample. Rinse beaker several times with ice-cold  $H_2O$ . Just before filtration is complete, wash sides of buchner with ca 100 mL ice-cold  $H_2O$  (or until clear filtrate comes thru). Up to this point do not let pad suck dry. Continue with suction until Filter-Cel pad seems dry. Transfer this mass, without paper, from buchner to original beaker. Break up mass with rod, dry overnight on steam bath, and then heat in oven

at 100° ca 30 min to remove all moisture (material must be dry or fat results will be low). Break up any lumps. Cool.

Prep. large Knorr extn tube of ca 200 mL capacity (glass tubing 5 cm diam., 12 cm high from shoulder to top of tube). Pack tube with asbestos tamped tightly to form ca 1 cm pad. Insert stem of tube into 2-hole rubber stopper in filtering bell jar connected to suction thru 2-way stopcock. Place 500 mL erlenmeyer within bell jar so that stem of tube passes thru neck of flask.

To beaker and contents, add 100 mL ether-pet ether (1+1) and macerate 3–4 min against sides of beaker with medium-size, stiff metal spatula. Decant into extn tube. Suck dry. Add 80 mL mixed ethers to beaker. Work as before 2 min. Transfer contents of beaker to extn tube, suck dry, and tamp with flat-end stirring rod until all ether is removed. To material in tube add 80 mL mixed ethers used just previously to rinse out beaker, mix thoroly with stirring rod few min, let stand 1 min, then suck dry, and tamp material as before. Make 2 addnl extns, turning suction on and off carefully to avoid loss of sample in erlenmeyer. Transfer to 1 L beaker. Evap. on steam bath, completely transfer fat with small amts of pet ether to weighed 150 mL beaker, carefully evap. pet ether on steam bath, dry at 100° to const wt (ca 30 min), cool, and weigh. Calc. % total fat on H<sub>2</sub>O-free basis.

Weigh duplicate samples of 1±0.03 g fat into 300 mL Florence flasks and add 4 mL glycerol-soda soln, **28.036(b)**. Heat flask carefully over asbestos gauze until bubbles start to appear; then hold flask ca 2–3 cm over the heated gauze until cloudiness or turbidity disappears and mixt. is perfectly clear. After mixt. first becomes clear, 30–60 sec addnl gentle heating ensures complete saponification. Cool; add few pieces of previously ignited pumice stone, 138 mL CO<sub>2</sub>-free H<sub>2</sub>O, and 3 mL H<sub>2</sub>SO<sub>4</sub> (1+4); and proceed as in **28.037**, using same app. Use 0.02N NaOH for titrn. Multiply mL 0.02N NaOH used by 1.1 and divide by wt fat used. Perform blank detn and make correction. Report number of mL 0.02N NaOH/g fat as "fat number."

#### Acetic and Propionic Acids (37)—Official Final Action

##### 14.094

##### Preparation of Sample

(a) *Air-dried bread*.—Prep. sample as in **14.090–14.091**.

(b) *Fresh bread*.—For analysis of fresh product, which may be difficult to air-dry without spoilage or loss of volatile acids, pass sample thru meat grinder equipped with  $\frac{1}{8}$ " (3 mm) hole plate, and divide finely by rubbing thru No. 8 sieve. Proceed with analysis promptly (24–48 hr) or preserve with CHCl<sub>3</sub> as follows:

To prepd bread in Mason jar filled to  $\frac{3}{4}$  capacity, add washed CHCl<sub>3</sub> absorbed in ca 1 g cotton (ca 5 mL CHCl<sub>3</sub>/500 mL (1 pt) container). Close jar tightly (self-sealing lids are recommended) and roll to mix contents thoroly. Store samples at ca 25° or refrigerate where higher temps occur.

##### 14.095

##### Reagents

See **18.051**.

##### 14.096

##### Apparatus

(a) *Distillation apparatus*.—Use steam distn app. **18.050(a)**, or gas-fired steam generator.

(b) *Chromatographic tubes*.—Approx. 15 × 250 mm or ca 15 × 450 mm, constricted at lower end to ca 4 mm id.

(c) *Test tubes*.—Approx. 16 × 150 mm, g-s.

(d) *Eyedropper pipet*.—Approx. 180 mm long.

##### 14.097

##### Distillation

Transfer 10 g air-dried bread or 15 g prepd fresh bread to 150

mL distg flask. Add 50 mL H<sub>2</sub>O and 10 mL ca 1N H<sub>2</sub>SO<sub>4</sub>. Mix thoroly and add 10 mL 20% *phosphotungstic acid soln*. Mix by swirling and add 40 g MgSO<sub>4</sub>·7H<sub>2</sub>O. Swirl again to partially dissolve salt. Mixt. should now be acid to *congo red paper*; if not, acidify with H<sub>2</sub>SO<sub>4</sub> (1+1). Connect to condenser and steam generator, heat contents of distg flask to bp, and distil 200 mL in 35–40 min. (Connect steam source just before heating bread solids suspension to prevent clogging of steam tube and to agitate bread solids.) Keep vol. in distg flask at ca 60–80 mL by means of small burner.

Transfer distillate to 400–600 mL beaker, add ca 10 mL ca 0.01N *formic acid*, make alk. to phthln with ca 1N NaOH, and evap. to ca 5 mL. Transfer to 25–30 mL g-s test tube, rinsing beaker with 3 portions H<sub>2</sub>O. If insol. material adheres, add few drops of ca 1N H<sub>2</sub>SO<sub>4</sub> with 1 rinse. Make alk. to phthln and evap. just to dryness by inserting tube in steam bath or in boiling H<sub>2</sub>O. (Air current hastens evapn.) Det. acetic and propionic acids in evapd distillate by the sepn technic, **18.057(d)**, after prepg, testing, and stdzg column as in **14.098**.

##### 14.098

##### Chromatographic Separation

(a) *Preparation of partition column*.—See **18.056**. (Where amt of propionic acid approaches 20 mg in column and definite band is observed below propionic acid band, use long chromatgc tube (450 mm) and ca 10 g silicic acid. Then take twice amts of H<sub>2</sub>O, indicator, and NH<sub>4</sub>OH as used for 5 g silicic acid.)

(b) *Test of silicic acid for suitability and standardization of column*.—Prep. stock solns of formic, acetic, and propionic acids (reagent grade) by dilg 5 mL acid to 250 mL and stdze acetic and propionic acids by titrg 1.0 mL aliquots with 0.01N NaOH, using cresol red indicator, to pink persisting ca 45 sec.

Prep. following dil. stock solns from stock solns and boiled H<sub>2</sub>O: Formic acid, 10 mL to 50 mL; acetic acid, 20 mL to 50 mL.

Prep. following trial mixts of formic acid and known amts of acetic and propionic acids:

Acids and Water	Mixture A; Stock Solns	Mixture B; Stock Solns	Mixture C
	mL	mL	
Formic	10	10	1 mL dil. stock soln
Acetic	10	10	1 mL dil. stock soln
Propionic	10	30	1 mL stock soln
Water	20	None	None
Total vol.	50	50	3 mL
Test aliquot	1	1	3 mL

(Above mixts cover range of acetic and propionic acids usually present when 15 g fresh bread preserved with propionate is used as initial sample.)

Pipet indicated test aliquots from mixts A and B and entire mixt. C into bottom of g-s test tubes (16 × 150 mm), neutze with ca 1N NaOH, using phthln, and add 1 drop excess.

Proceed with evapn, sepn, and titrn as in **18.057(c)** and **(d)**. Calc. results for acetic and propionic acids to mg/100 g sample. Following factors are based on 15 g fresh bread or 10 g air-dried bread:

Fresh bread (mg/100 g):

Acetic acid = 4.00 × mL 0.01N Ba(OH)<sub>2</sub>

Propionic acid = 4.93 × mL 0.01N Ba(OH)<sub>2</sub>

Air-dried bread (mg/100 g):

Acetic acid = 6.00 × mL 0.01N Ba(OH)<sub>2</sub>

Propionic acid = 7.40 × mL 0.01N Ba(OH)<sub>2</sub>

(c) *Identification of acids.*—See also 18.058 and 14.101. With trial mixts *A*, *B*, and *C* and with most breads to which propionate has been added, only 3 definite bands appear on column and they elute in this order: propionic, acetic, and formic acids. Method provides for addn of enough formic acid to supply definite following band to ensure that acetic acid is completely eluted. Amt of mobile solv. required to move each acid from top of column to point of emergence is function of concn of that acid. For amt of acetic acid normally present in bread, differences in threshold vol. are not critical. To identify propionic acid by threshold vol., however, it is necessary to check threshold vol. for the concn indicated by titrn. Sepn of mixts *A*, *B*, and *C* supply enough data for amt normally found. Threshold vols may be predicted for intervening concns by plotting concn against detd threshold vols.

Due to differences in propionic threshold vol., make change in mobile solv. from 1% BuOH-CHCl<sub>3</sub> to 10% BuOH-CHCl<sub>3</sub> at a const vol. of 1% BuOH-CHCl<sub>3</sub> rather than at propionic acid threshold, preferably when greater part of propionic acid has been eluted. Then acetic acid threshold vol. will not be affected by changes in propionic acid threshold vol.

Acids as sepd in BuOH-CHCl<sub>3</sub> solns may be further identified by formation of mercurous acetate or mercurous propionate crystals (JAOAC 28, 644(1945)) or by paper chromatog, 14.101.

#### *Identification of Volatile Acids by Paper Chromatography (38)—Official Final Action*

(Also applicable to confirming identity of acids sepd by 18.054–18.058 and as qual. test for propionates in bread)

14.099

#### *Apparatus*

*Chromatographic tank and accessories.*—See 29.007.

14.100

#### *Reagents*

(a) *Mobile solvent.*—Mix acetone, *tert*-BuOH, *n*-BuOH, and NH<sub>4</sub>OH (2 + 1 + 1 + 1). Prep. fresh daily.

(b) *Chromogenic reagent.*—Add 200 mg each Me red and bromothymol blue to mixt. of 100 mL formalin and 400 mL alcohol. Adjust to pH 5.2 with 0.1*N* NaOH.

(c) *Acids std solns.*—Pipet 1 mL each acetic, propionic, butyric, and valeric acids into sep. 100 mL vol. flasks and dil. to vol. with H<sub>2</sub>O to prep. stock solns. Pipet 1 mL each of these stock solns into sep. 25 mL beakers; pipet 1 mL each of the 4 stock solns into single 25 mL beaker to prep. known mixt. Neutze acids and mixt. with 0.1*N* NaOH, using cresol red indicator, 16.222(f), avoiding excess alkali. Evap. to ca 0.5 mL, or evap. just to dryness and take up in 0.5 mL H<sub>2</sub>O.

14.101

#### *Technic*

Steam distil 20 g well mixed sample as in 14.097, collecting 200 mL distillate. Immediately neutze distillate, using cresol red, 16.222(f), and 0.1*N* NaOH. Evap. to 0.5 mL, or evap. just to dryness and then take up in 0.5 mL H<sub>2</sub>O. (To save time, place distillate in large porcelain evapg dish, and evap. to 5–10 mL; transfer to 25 mL beaker and evap. to 0.5 mL.)

With hard pencil, rule starting line 2.5 cm from bottom edge of 8 × 8" Whatman No. 1 unwashed chromatgc paper. Spot seven 1  $\mu$ L spots with 1  $\mu$ L pipet on paper, 2.5 cm apart, leaving 2.5 cm margin, to permit 1 spot for each acid, 1 for mixt., and 2 for unknowns. Spot in following order: acetic, propionic, unknown, mixt. of 4, unknown, butyric, valeric. Let dry. Clip paper to glass rod and suspend in tank with 50 mL mobile solv. in trough. (Since mobile solv. is heavy liq., use 3 clips to fasten paper to glass rod to prevent sagging and to give more uniform solv. front. Do not sat. tank with mobile solv. before inserting

paper.) Seal glass cover with cellophane or other suitable tape and let develop until solv. is ca 2.5 cm from top of paper. Remove paper from tank, let air dry, and spray on front side with chromogenic reagent. (Spraying should be uniform and rather heavy but not to extent that chromogenic reagent runs or drips.) Faint yellow spots indicate presence of acids; heavier blue spots are due to Na ion. To intensify acid spots, place paper in atm. of NH<sub>3</sub> fumes momentarily (e.g., by placing ca 50 mL NH<sub>4</sub>OH in 2 L beaker, rolling paper, and exposing to fumes by placing each end in beaker momentarily); entire paper immediately turns green. Remove paper from NH<sub>3</sub> fumes. Acids gradually appear as red spots, and presence of specific acids in sample may be detd by comparing their *R<sub>f</sub>* values with those of mixt. and individual acids.

Since color of acids is not stable, mark spots with pencil as soon as they are completely developed.

#### 14.102 ★ Citric Acid (39)—Official First Action ★

See 13.088, 10th ed. (Caution: See 51.059.)

#### 14.103 Ash (40)—Official Final Action

Use 3–5 g prepd sample, 14.090, and proceed as in 14.006 or 14.008.

#### 14.104 Chlorides in Ash as Sodium Chloride Official Final Action

See 32.025–32.030.

#### Iron—Official Final Action

14.105

#### *Preparation of Sample*

Slice bread, let air dry until in equilibrium with air, and crush to ca 20-mesh size on wooden surface with wooden rolling pin. (Grinding may be done in mill if tests show no increase in Fe due to grinding of particular material under examination. In general, grinding in mills increases Fe content.)

Proceed as in 14.013.

#### 14.106 Calcium—Official Final Action

See 14.014.

#### Vitamins in Enriched Bread—Official Final Action

14.107

#### *Preparation of Sample*

Det. fresh wt of entire sample taken for drying, usually 6 loaves of 1 lb size or alternate slices from 6 loaves of 1.5 lb size. Slice unsliced bread into slices ca 1 oz each. Spread slices on coarse screens, elevated to provide good air circulation, and let air dry until crisp enough for efficient grinding. (If riboflavin is also to be detd, drying should be done in absence of light.) Weigh air-dried bread and grind entire amt to pass No. 20 sieve. Mix well, and store in air-tight glass jars at ca 10°. Det. air-dry wt: fresh wt ratio for subsequent use in calcn of results to fresh basis.

Proceed as in Chapter 43.

#### 14.108 Protein—Official Final Action

Det. N as in 2.057, using 2 g prepd air-dried ground sample, 14.090. Multiply % N by factor 5.7 to obtain % protein.

#### 14.109 Fat (Acid Hydrolysis Method) Official Final Action

See 14.019.

★ Surplus method—see inside front cover.

**14.110 Sterols (As Cholesterol)—Official Final Action**

Weigh 5 g air-dried, ground sample and proceed as in 14.149.

**14.111 Crude Fiber—Official Final Action**

(For bread and other baked products not contg fruit)

Proceed as in 7.065.

**14.112 Sugars—Official Final Action**

(a) *Reducing sugars*.—Prep. sample as in 7.079, par. 1 and 2. Proceed as in 31.038, using 25 mL aliquot (representing 2 g sample). Express results as glucose or invert sugar.

(b) *Sucrose*.—Proceed as in 7.079.

**Lactose (41)—Official First Action****14.113****Apparatus**

(a) *Rack*.—Metal rack so constructed as to prevent agitation of tubes while in boiling H<sub>2</sub>O bath.

(b) *Titration stirrer*.—For stirring soln during titrn; rod made from glass tubing, sealed and flared at lower end to form button-like foot, is convenient. Make side arm consisting of several layers adhesive tape attached near enough to top of tube to prevent breaking bottom of titrn tube.

**14.114****Reagents**

(a) *Yeast suspension*.—Wash 25 g fresh com. bakers yeast with five 100 mL portions H<sub>2</sub>O or until last washings are clear. Centrf. and decant after each wash. Suspend in 100 mL H<sub>2</sub>O and store 24 hr at 0–4° before use. Discard after 1 week.

(b) *Yeast nutrient soln*.—Dissolve 1.7 g Bacto peptone (Difco Laboratories), 0.50 g K<sub>2</sub>HPO<sub>4</sub>, and 0.33 g MgSO<sub>4</sub>·7H<sub>2</sub>O in H<sub>2</sub>O, and dil. to 100 mL with H<sub>2</sub>O.

(c) *Protein precipitant*.—Dissolve 50 g Na tungstate and 6 g Na<sub>2</sub>HPO<sub>4</sub> in 200 mL H<sub>2</sub>O. Slowly add 220 mL 2*N* HCl, mix, and dil. to 500 mL with H<sub>2</sub>O.

(d) *Somogyi reagent*.—Dissolve 12 g Rochelle salt, 20 g Na<sub>2</sub>CO<sub>3</sub>, and 25 g NaHCO<sub>3</sub> in ca 500 mL H<sub>2</sub>O and pour into soln, with stirring, 6.5 g CuSO<sub>4</sub>·5H<sub>2</sub>O dissolved in ca 100 mL H<sub>2</sub>O; add soln of 10 g KI, 0.80 g KIO<sub>3</sub>, and 18 g K<sub>2</sub>C<sub>2</sub>O<sub>4</sub>·H<sub>2</sub>O, and dil. to 1 L. (Only KIO<sub>3</sub> need be weighed accurately.) Let stand few days; then filter off any small amt of ppt.

(e) *Sodium thiosulfate soln*.—0.005*N*. Prep. daily by dilg 0.1*N* soln, 50.037–50.038.

**14.115****Determination**

Weigh 10 g air-dried bread, add 5 g Filter-Cel, and mix well. Transfer mixt. to extn thimble (ca 30 × 77 mm), cover with cotton pad, place in Soxhlet extractor, add 150 mL alcohol-H<sub>2</sub>O mixt. (126 mL alcohol + 61 mL H<sub>2</sub>O), and ext overnight on hot plate set at medium heat. Transfer ext to 250 mL beaker (previously marked at 40 mL), evap. on steam bath with aid of weak air current to ca 40 mL, and transfer to 100 mL vol. flask, rinsing well. Cool, dil. to vol., and mix well. Pipet 10 mL aliquot into 50 mL erlenmeyer; add 6 mL yeast suspension and 5 mL yeast nutrient soln. Prep. blank test, using 10 mL H<sub>2</sub>O in place of sample ext. Stopper flask with 1-hole rubber stopper fitted with piece of 6 mm (not smaller) glass tubing ca 10 cm long. Shake at moderate rate 2.5 hr in const temp. H<sub>2</sub>O bath at 30°.

Transfer to 50 mL centrf. tube and centrf. ca 10 min at ca 1000 rpm. Decant supernate into 50 mL vol. flask. Rinse erlenmeyer with 10 mL H<sub>2</sub>O, decanting onto residue in centrf. tube. Mix residue and H<sub>2</sub>O with glass rod. Centrf., and combine washing with previous supernate in 50 mL vol. flask. Repeat washing,

using 10 mL H<sub>2</sub>O. Add, with shaking, 2.5 mL protein precipitant. Dil. to vol., mix well, and filter, discarding first few mL filtrate. (This is convenient stopping point; stopper flask for continuation next day.)

Pipet 5.0 mL clear filtrate into Pyrex test tube (22 × 175 mm) and neutze to phenol red end point with 0.5*N* NaOH. Add 5.0 mL Somogyi reagent, mix by rotary motion, and add 2 drops benzene. Cap tube with glass bulb and place in metal rack. Immerse rack contg tubes in vigorously boiling H<sub>2</sub>O bath exactly 15 min. Cool, avoiding agitation, to ca 35° in H<sub>2</sub>O bath. Add 2.5 mL 2*N* H<sub>2</sub>SO<sub>4</sub>, shake with rotary motion, let stand 1–2 min, and titr. excess I with 0.005*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, adding 6 drops 1% starch indicator near end of titrn. (Titrn should be finished in 30 min.) From difference between titrn value of blank (H<sub>2</sub>O, yeast suspension, and yeast nutrient) and that of sample, det. wt lactose present from std curve. This value in mg lactose represents amt in 100 mg air-dry bread or % lactose.

Prep. std curve, using 0–4.5 mg pure *lactose hydrate* (0, 0.2, 0.5, 1.0, 2.0, 3.0, 4.0, and 4.5 mg from portions of soln contg 1.0 mg/mL) in enough H<sub>2</sub>O to make 5 mL. Add 5.0 mL Somogyi reagent, mix by rotary motion, and add 2 drops benzene. Proceed as above from "Cap tube . . ." Plot difference between titrn value for 0 mg lactose and that for each lactose soln against corresponding lactose concn in mg.

**14.116 Hydrogen-Ion Activity (pH)—Official Final Action**

See 14.022.

**BAKED PRODUCTS****Mineral Oil (42)—Official First Action**

(Caution: See 51.004, 51.011, 51.056, and 51.073.)

**14.117****Reagents and Apparatus**

(a) *Chromatographic tube*.—250 mL dispensing burets or tube 30 × 450 mm, with stopcock at lower constricted end.

(b) *Alumina*.—Adsorption, Brockmann I, basic, or equiv., 80–200 mesh, suitable for chromatgy, pH 9–11 in aq. slurry (Fisher Scientific Co. No. A-540, A-941, or equiv.).

**14.118****Preparation of Sample and Oil Separation**

Dry weighed sample in oven at 50° or in air on nonabsorbent surface until crisp and brittle enough to crush and grind (do not char). Grind, mix thoroly, weigh, and store in air-tight container. Det. dry wt: fresh wt ratio for use in calcg results to fresh basis and detg sample wt to be used, calcd to fresh basis.

Weigh dried sample equiv. to 225 g, fresh basis, into large mortar. Add, with stirring, 50 mL HCl (1+1) until thoroly mixed and uniformly wet. Let stand ca 1 hr. Break up lumps with pestle or spatula, transfer to 800 mL beaker, add 450 mL CHCl<sub>3</sub>, and heat on steam bath until CHCl<sub>3</sub> boils, stirring constantly. Transfer to large size high-speed blender, blend, and decant CHCl<sub>3</sub> thru buchner fitted with rapid paper, using suction. Repeat blending, decanting, and filtering with 2 addnl 300 mL portions CHCl<sub>3</sub>. Dry combined CHCl<sub>3</sub> exts by passing thru 8 cm Na<sub>2</sub>SO<sub>4</sub> in 3 cm diam. column. If filter or Na<sub>2</sub>SO<sub>4</sub> column becomes clogged, loosen surface enough to permit free flow. Wash Na<sub>2</sub>SO<sub>4</sub> with ca 50 mL CHCl<sub>3</sub>. Evap. combined CHCl<sub>3</sub> to small vol. on steam bath under dry air stream. Transfer quant. to weighed beaker, evap. remainder of solv., dry oil overnight in convection oven at 100°, and weigh.

**14.119****Preparation of Alumina Column**

Pack pledget of glass wool into constricted end of glass tube. Add, thru powder funnel, 175 g alumina, tapping tube to ensure

uniform packing. Cover surface with disk cut from rapid filter paper of slightly smaller diam. than inside of tube. Prewash column with 200 mL pet ether. Just before last of pet ether settles into alumina, stop flow.

**14.120****Determination**

Accurately weigh 5 g warmed, well mixed, extd oil into small beaker. Mix well with 5–10 mL pet ether. Pour carefully onto alumina column, open stopcock, and collect eluate at rate <5 mL/min. Close stopcock when ether-oil mixt. has settled to just above surface of alumina. Rinse sample beaker with two 5 mL portions pet ether, rinsing sides of column with each rinse. Open stopcock and let ether settle almost to surface of alumina. Fill column with pet ether. Continue adding pet ether to column until total of 400 mL collects. Evap. pet ether to small vol. on steam bath, using gentle stream of dry air to aid solv. removal. Stirring rod placed in flask will help prevent superheating and possible boiling over. Transfer quant. to small weighed beaker. Evap. to dryness on warm surface, using gentle stream of dry air. Dry in convection oven 1 hr at 100°. Calc. % by wt of this unsaponifiable oil to fresh basis of product.

Transfer ca 2 drops residue oil to face of NaCl or Irtran plate. Cover with another plate and prep. IR spectrum. Prep. similar curve, using USP mineral oil. If vol. of residue oil is too small to transfer to plate directly, transfer with aid of CS<sub>2</sub>. Evap. solv. completely before covering plate with second plate. Peaks occur at 3.4, 6.82, and 7.25  $\mu$ m.

Obtain refractive index on another drop or two of residue oil and compare with refractive index of USP mineral oil read at same temp.

**BAKED PRODUCTS OTHER THAN BREAD  
(NOT CONTAINING FRUIT) (43)**

**14.121 Solids—Official Final Action**

**14.124 Fat—Official Final Action**

See 14.019.

**14.125 Sterols (As Cholesterol)—Official First Action**

Weigh 5 g air-dried, ground sample and proceed as in 14.149.

**14.126 Crude Fiber—Official Final Action**

See 7.065.

**14.127 Sugars—Official Final Action**

See 14.112.

**14.128 Hydrogen-Ion Activity (pH)—Official Final Action**

See 14.022.

**14.129 Acetic and Propionic Acids in Cake (37)  
Official Final Action**

Proceed as in 14.097, using 15 g sample prepd as for fresh bread or fresh bread preserved with CHCl<sub>3</sub>.

**FIG BARS AND RAISIN-FILLED CRACKERS (44)  
OFFICIAL FINAL ACTION**

**14.130 Moisture**

Place 25–30 g prepd sand and short stirring rod in dish ca 55 mm diam. and 40 mm deep, fitted with cover. Dry thoroly, cover dish, cool in desiccator, and weigh immediately. Remove cover, place 3–5 g prepd sample, 14.090(b), in dish, and weigh accurately. Remove dish contg sand, stirring rod, and weighed sample from balance. Add 5–10 mL H<sub>2</sub>O and mix with the sand. Heat carefully on H<sub>2</sub>O bath, stirring at 2–3 min intervals, until excess H<sub>2</sub>O is removed and contents of dish are consistency of heavy paste. Place uncovered dish in vac. oven and dry ca 16 hr at 70° under pressure  $\leq$ 50 mm Hg (6.7 kPa). After drying, cover dish, transfer to desiccator, cool to room temp., and weigh immediately.

*Notes:* Quartz sand that passes No. 40 sieve but is retained on No. 60 sieve, has been digested with HCl, washed free of acid, and ignited, is recommended. Al dishes with fit-over covers are most convenient. Dish can be set in cover during heating on H<sub>2</sub>O bath and during oven-drying period. After drying, cover can be easily and quickly refitted on dish as it is transferred to desiccator.

**14.131 Fat**

*(Caution: See 51.011, 51.054, and 51.073.)*

Accurately weigh ca 2 g well mixed sample, prepd by grinding twice thru food chopper, and transfer to Mojonnier tube. Add 2 mL alcohol, warm to 60–70°, and shake gently until sample is thoroly disintegrated and mixed with alcohol. Add 10 mL HCl (25+11). Place tube in H<sub>2</sub>O bath held at 70–80° and shake frequently until sample is thoroly digested (40–80 min).

If weighed sample cannot be transferred to tube directly, digest in 50 mL beaker. Transfer digested mixt. to tube as completely as possible by draining from lip of beaker down small stirring rod. Rinse beaker thoroly with 10 mL alcohol, transfer to tube, mix thoroly, and cool. Rinse beaker with portions of first 25 mL ether added for first extn. Repeat rinsing with portions of pet ether (bp <60°) as it is added for first extn. Rinse thoroly so that all fat is transferred to extn tube. (After digestion, all particles should be completely disintegrated, except hard seeds (in fig fillers) and strong fibers. Very small amt of fat may be retained by such particles after digestion, but in analysis of biscuits and crackers this loss will be within experimental error.)

When digesting in extn tube, add 10 mL alcohol to digested charge and cool. (Level of liq. should be in neck of Mojonnier tube just below pour-off level.) Add 25 mL ether, stopper flask with cork, Neoprene, or other synthetic rubber stopper not affected by solvs, and shake thoroly ca 1 min. Carefully release pressure so that none of solv. contg fat is lost. Wash adhering solv. and fat from stopper into extn tube with few mL pet ether. (Glass wash bottle producing fine jet is convenient.) Let mixt. stand few min; then add 25 mL pet ether (bp <60°), stopper tube tightly, and again shake thoroly ca 1 min. Carefully release pressure, remove stopper, and again wash adhering solv. and fat into tube with few mL of pet ether. Let mixt. stand until ether layer is clear (10–20 min), or centrf. 20 min at ca 600 rpm.

Pour off as much as possible of clear ether-fat soln thru small, fast filter by tilting tube gradually. (Plug of ether-extd cotton packed just firmly enough in stem of funnel to let ether pass freely makes excellent filter for these extns.) Catch ether-fat solns from extns in clean 250 mL beaker or flask. Re-ext digested sample remaining in tube 3 times more as for first extn. (Vol. of ether may be reduced to 15 or 20 mL for last 3 extns.) Wash mouth of tube each time after draining ether-fat soln, and filter this ether thru funnel into receptacle.

Evap. combined ethers from extns with air current or suction. After ethers are practically off, heat ca 10 min on hot H<sub>2</sub>O or steam bath to drive off most of alcohol and H<sub>2</sub>O carried over with ethers. Transfer beaker to 100° oven, dry 1 hr, remove, and let cool. Redissolve dried fat in 15–20 mL mixt. of equal parts of ether and pet ether, and filter thru small fat-free paper into beaker or flask previously dried at 100°, cooled in desiccator, and weighed.

Wash all traces of fat from first receptacle, filter paper, and funnel into the tared beaker or flask with jet of pet ether from wash bottle. Evap. ethers from tared receptacle with air current or suction and dry purified fat to const wt in 100° oven (1–1.5 hr). Cool in desiccator and weigh as soon as room temp. is attained. Make blank detns on reagents.

*Notes:* Good quality rubber stoppers thoroly cleaned with alcohol are satisfactory for stoppering extn tubes. Remove stoppers from tubes after each shaking period and do not allow to remain in contact with solvs longer than necessary. Solv. may have some action on rubber. Very fine grain cork stoppers washed with alcohol and ether are also satisfactory for stoppering extn tubes, provided leakage of solvs can be prevented during shaking.

If trouble is experienced in releasing pressure after shaking extn tube contg ethers, cool tube slightly by holding it under stream of cold H<sub>2</sub>O before removing stopper.

All beakers are very satisfactory for weighing purified fat; they are light wt and cool to room temp. rapidly.

#### MACARONI, EGG NOODLES, AND SIMILAR PRODUCTS—OFFICIAL FINAL ACTION

##### 14.132 Collection and Preparation of Sample (45)

Select from lot to be analyzed enough strips or pieces to assure representative sample, break these into small fragments with hands or in mill, and mix well. Grind 300–500 g in mill until all material passes thru No. 20 sieve. Keep ground sample in sealed container to prevent moisture changes.

#### Total Solids and Moisture

##### 14.133 Vacuum Oven Method (46)

Use 2 g prepd sample, 14.132, and proceed as in 14.003.

##### 14.134 Air Oven Method

Use 2 g prepd sample, 14.132, and proceed as in 14.004.

##### 14.135 Ash

Use 3–5 g prepd sample, 14.132, and proceed as in 14.006.

##### 14.136 Original Ash in Macaroni Products Containing Added Salt But Not Containing Added Eggs (47)

Proceed as in 14.006. Dissolve ash in 25 mL HNO<sub>3</sub> (1+3), transfer to 150 mL beaker, dil. to 75 mL with H<sub>2</sub>O, and boil 15 min, maintaining original vol. (necessary to convert all phosphate to ortho form). Det. P<sub>2</sub>O<sub>5</sub> as in 7.119. P<sub>2</sub>O<sub>5</sub> × 2 = NaCl-free ash.

##### 14.137 Chlorides in Ash as Sodium Chloride (48) Official First Action

See 32.025–32.030.

##### 14.138 Iron

See 14.013.

##### 14.139 Vitamins in Enriched Macaroni and Noodle Products

See Chapter 43.

##### 14.140 Fat (Acid Hydrolysis Method) (49)

Place 2 g sample in Mojonnier or Roehrig extn tube, add 2 mL alcohol to prevent lumping on addn of acid, and shake to moisten all particles. Add 10 mL HCl (25+11), mix well, set tube in H<sub>2</sub>O bath held at 70–80°, and shake at frequent intervals during 30–40 min. Fill to within 1–2 mL of mark with alcohol and cool. Add 25 mL ether and shake mixt. well. Then add 25 mL pet ether (bp <60°) and mix well. Let stand until upper liq. is practically clear and proceed as in 14.019, beginning "Draw off as much as possible . . ."

##### 14.141 Crude Fiber

See 7.065.

##### 14.142 Protein (50)

Det. N as in 2.057, using 1 g prepd sample, 14.132. % protein = % N × 5.7.

##### 14.143 Water-Soluble Protein-Nitrogen Precipitable by 40 Per Cent Alcohol

See 14.027.

##### 14.144 Hydrogen-Ion Activity (pH)

See 14.022.

##### 14.145 Lipid and Lipid Phosphorus

Proceed as in 14.028 and 14.029.

#### Unsaponifiable Residue (51)

##### 14.146 Reagents and Apparatus

See 17.017 and 17.018. (Concd KOH soln is not needed.)

##### 14.147

##### Determination

Weigh 10 g sample, ground to pass No. 20 sieve, into 500 mL erlenmeyer and add, with shaking, 30 mL HCl (1+1). Heat on steam bath 30 min, shaking occasionally to break up any lumps. While cooling inclined flask under tap, carefully add, with shaking, 30 g KOH pellets at such rate that liq. may boil, but not so violently as to cause loss by spurling. Place flask on steam bath while still hot, cover with small watch glass, and heat 3 hr, swirling occasionally to carry down any material adhering to sides. Cool until just warm, add 30 mL alcohol and 50 mL H<sub>2</sub>O, and mix well. Add 100 mL ether, swirl vigorously 1 min, and transfer to separator, washing flask with 50 and 25 mL portions ether. Wash flask with 50 mL KOH soln, pour washings into separator in slow stream while gently swirling liq., and continue gentle swirling 10–15 sec. Proceed as in 17.019, beginning "Let liq. sep. (ca 10 min) . . ." but omitting first acid wash. If emulsion forms and does not break to give sharp interface in 10 min, pour 5 mL alcohol into separator and let stand until sharp interface appears.

#### Sterols (as Cholesterol)

##### 14.148 Bromination Method (51)

Det. sterols in unsaponifiable matter as in 17.022. However, to unsaponifiable matter from egg-free products or from any product contg <0.23% unsaponifiable matter (as-is basis), add

10 mg cholesterol before applying cholesterol method and correct result accordingly. (For the added cholesterol use highest quality obtainable (mp  $\geq 147^\circ$ ) and test its purity by carrying 20 mg thru detn.)

#### 14.149 Digitonin Method (52)

(Caution; See 51.011(a) and 51.054.)

Weigh 5 g sample, ground to pass No. 20 or finer sieve, into 300 mL erlenmeyer and add, with shaking, 15 mL HCl (1+1) in such manner as to keep particles on sides at min. Heat on steam bath 30 min, shaking frequently to break up any lumps and ensure complete hydrolysis. While cooling inclined flask under tap, carefully add, with swirling, 15 g KOH pellets at such rate that liq. may boil, but not so violently as to cause loss by spurting. Cool, add 20 mL alcohol, rinsing down sides of flask, and heat on steam bath 45 min with air condenser, shaking frequently.

Add 25 mL H<sub>2</sub>O, rinsing down sides of flask, mix well, and cool. Add 50 mL ether, vigorously swirl mixt. 1 min, and transfer to 500 mL separator. Wash flask with 25 and 10 mL portions ether and with 50 mL 1% KOH soln, pouring washings into separator in slow stream while gently swirling liq., and continue gentle swirling 10–15 sec. Let liq. sep. and slowly drain soap soln into 250 mL separator, but do not drain any small amt of emulsion or of insol. matter at interface. Rinse down sides of 500 mL separator with 5 mL 1% KOH soln and drain this into smaller separator. Add 25 mL ether to smaller separator and shake vigorously ca 1 min. After liqs sep., discard lower layer. Add ether layer to soln in larger separator, rinsing 250 mL separator with 10 mL ether. Wash ether soln as before with 3 addnl 50 mL portions 1% KOH, still keeping any insol. matter or emulsion in separator. Wash ether soln twice by swirling with 50 mL H<sub>2</sub>O. Finally drain as much of aq. layer as possible without loss of ether soln. Add porcelain chip to 300 mL erlenmeyer, transfer ether to flask, rinse separator with three 5 mL portions ether, and rinse stem of separator with ether. Add rinsings to flask and evap. ether on steam bath.

Dissolve residue in 5 mL acetone; filter, with suction if necessary, thru Knorr-type (Allihn) extn tube contg medium porosity fritted glass disk (Ace Glass, Inc., No. 7195-08, or equiv.), covered with few g washed and ignited sand, into 100 mL centr. tube or test tube under bell jar. Wash flask and tube with three 4 mL portions acetone, and rinse tube and stem with few mL acetone (total vol. ca 20 mL). Add 5 mL freshly prep'd digitonin soln in 80% alcohol contg 40 mg digitonin. (Hasten soln of digitonin by warming to ca 40–50° under hot H<sub>2</sub>O tap.) (Products contg >6% egg yolk solids or equiv. (moisture-free basis) require addnl digitonin soln or use of aliquot portion for pptn.) Rotate to mix. Place porcelain chip in the tube, suspend tube in steam bath with small amt of steam to avoid boiling or spattering, evap. nearly to dryness, add 50 mL hot H<sub>2</sub>O (near bp), and stir well with glass rod to disperse ppt and dissolve excess digitonin. Place tube in boiling H<sub>2</sub>O bath and hold several min with frequent stirring. Cool to ca 60°, add 25 mL acetone, mix well by stirring, and cool to room temp. in beaker of cold H<sub>2</sub>O.

When ppt has nearly all settled (ca 15 min), remove glass rod, rinsing off any adhering ppt with acetone. Decant into previously dried and weighed gooch (preferably 10 mL capacity) contg asbestos pad covered with ca 1 g washed and ignited sand. Using wash bottle, wash tube several times with few mL portions acetone to transfer all ppt. (Caution: Avoid transfer of any particles of chips.) Finally rinse crucible with acetone to dissolve any fat-like material, rinse with 5 mL ether, dry 30 min at 100°, and weigh. Check wt after second 30 min of drying. Wt resi-

due  $\times 0.243$  = wt sterol. Report as % sterol on moisture-free basis.

#### Fluorometric Method (53)—Official First Action

(Caution: See 51.008, 51.018, 51.022, and 51.056.)

#### 14.150

#### Apparatus

(a) *Soxhlet extractor*.—Medium-size, with 250 mL flask and 33  $\times$  94 mm thimble.

(b) *Spectrophotofluorometer (Fluorescence spectrophotometer)*.—With high intensity Xe source, and grating or prism excitation and emission monochromators, each with resolution  $\leq 5$  nm. Instrument should be able to detect  $\leq 1$  ng quinine sulfate/mL 0.1N H<sub>2</sub>SO<sub>4</sub>. Excitation wavelength, 546 nm; emission wavelength 577 nm. Cells must be scrupulously clean on all 4 sides. Rinse exterior of cells with alcohol and dry with lint-free absorbent tissue before placing in instrument.

#### 14.151

#### Reagents

(a) *Cholesterol std soln*.—Prep. soln contg 6.0 mg cholesterol/100 mL CHCl<sub>3</sub>. Pipet duplicate 2 mL aliquots into 25 mL erlenmeyers and evap. to dryness on steam bath under gentle stream of air. Proceed as in 14.152, beginning "Into each flask, . . ."

(b) *Chloroform-acetic anhydride soln*.—(5 + 1). Freshly prep'd for each series of detns. Use Ac<sub>2</sub>O from fresh or recently opened bottle.

#### 14.152

#### Determination

Ext ca 5 g noodles, ground to pass No. 40 or finer sieve, in Soxhlet 4 hr with ca 120 mL vigorously boiling CHCl<sub>3</sub> and boiling chip. Wash ext into 100 mL vol. flask with CHCl<sub>3</sub>, cool, dil. to vol., and mix.

Pipet duplicate 2 mL aliquots into 25 mL erlenmeyers and evap. to dryness on steam bath under gentle stream of air. Into each flask, pipet 10 mL CHCl<sub>3</sub>-Ac<sub>2</sub>O; swirl to mix; let stand 15 min; then add exactly 0.4 mL H<sub>2</sub>SO<sub>4</sub>. Stopper, mix, and let stand 40 min. (Solns should contain no turbidity due to H<sub>2</sub>O.) Read within 1 hr from end of fluorescence development step.

Adjust fluorometer to ca 60% T with cholesterol std soln. Transfer ca 4 mL sample soln to clean 10  $\times$  10 mm cell and read. Use 5 mL CHCl<sub>3</sub>-Ac<sub>2</sub>O and 0.2 mL H<sub>2</sub>SO<sub>4</sub> as blank.

#### 14.153

#### Calculation

% Cholesterol in sample =  $100 (\text{mL}) \times C \times (F/F') \times 100/W$ , where  $C$  is concn of ref. std in mg/mL (0.060);  $F$  and  $F'$  are, resp., av. fluorescence at 577 nm of sample duplicates and std duplicates, each corrected for blank; and  $W$  is mg sample.

#### 14.154 Extraction, Separation, and

#### Identification of Coloring Matter\* (54)

Place ca 500 g coarsely ground sample (depending on amt of color present) in 1 L erlenmeyer, add ca 700 mL 80% alcohol, and shake at intervals for 24 hr, or until no more color is extd. Place in refrigerator overnight to permit dissolved protein to ppt. Filter, and evap. filtrate to 100 mL. Add ca ¼ vol. 25% NaCl soln and slight excess of NH<sub>4</sub>OH to filtrate; cool, and transfer to separator. Ext with equal vol. pet ether, bp <60°; sep. lower layer and repeat extns with addnl portions solv. until no more color is extd. Reserve lower layer, if colored, for further treatment; if colorless, discard.

Combine pet ether exts and wash with several small portions

\* See 34.015(b) for corresponding color numbers.

NH<sub>4</sub>OH (1+50) to remove any material mech. adhering to solv. This ether soln contains fats; it also may contain oil-sol. synthetic dyes, which can be identified as in (a). If colored, immediately acidify alk. aq. soln, freed from fat and oil-sol. synthetic dyes, with HOAc and ext in 25 mL portions with two 50 mL portions ether. Solv., if colored, may contain turmeric, annatto, and trace of saffron, which may be identified as in (b).

If original aq. soln, freed from ether-sol. colors, is still colored and H<sub>2</sub>O-sol. dyes are suspected, proceed as follows: Ext aq. soln with 50 mL portions *isoamyl alcohol* to remove balance of saffron, as well as common orange dyes and Martius yellow; to sep., proceed as in (c). Drain lower aq. layer, which, if colored, may contain naphthol yellow S, tartrazine, and sunset yellow. Ext these dyes with isoamyl alcohol after acidifying soln with HCl to ca 1*N*. Remove tartrazine from solv. with 0.25*N* HCl. Sunset yellow is also removed at this stage with slightly lower acid concn, and naphthol yellow S from nearly neut. soln. Proceed as in Chap. 34.

(a) Ext original pet ether ext with two or three 10 mL portions of mixt. consisting of HCl and HOAc (1+5).

In presence of yellow OB or yellow AB, pink or red soln is obtained. Test small portion of this acid ext with few drops 40% *SnCl*<sub>2</sub> soln, which in presence of these dyes causes either decoloration or decided fading. Dil. balance of acid ext with H<sub>2</sub>O, make slightly alk., and ext color with pet ether. Wash solv. with two 5 mL portions H<sub>2</sub>O to remove excess alkali. Proceed as in Chap. 34. Remaining coloring matters in pet ether ext may be due to natural coloring matter of wheat or coloring matter of egg. Coloring principle of egg yolk, lutein, when heated with alc. *FeCl*<sub>3</sub>, produces green soln. This test, however, is not specific for lutein; carotene and xanthophyll give similar reactions.

(b) Wash ether ext with 5 mL portions H<sub>2</sub>O to remove excess acid. To remove annatto and traces of saffron, wash successively with 20 mL portions 5% *NaHCO*<sub>3</sub> soln. Divide alk. soln into 2 portions. Heat one portion to 60° on steam bath, dye the color on unmordanted cotton, and compare spot tests with a std. Acidify remaining portion of the alk. annatto soln with HOAc and re-ext with ether. Divide ether ext into 2 small casseroles and evap. to dryness. Dissolve contents of one casserole in 10 mL NH<sub>4</sub>OH (1+9) and impregnate on strip of cotton or filter paper. Orange-yellow to orange-red stain is obtained, depending on amt of dye present. Dry filter paper or cotton, add drop 40% *SnCl*<sub>2</sub> soln, and again dry. In presence of annatto, purple stain is produced. Spot contents of other casserole with H<sub>2</sub>SO<sub>4</sub> and HNO<sub>3</sub>, which yield blue and greenish-blue colors, resp.

Transfer 2 portions (ca 10 mL each) of original ether ext, from which annatto has been removed, into test tubes and treat with equal vol. 10% NaOH soln and equal vol. HCl (1+1), resp. In presence of turmeric (curcuma), alk. soln is reddish brown; acid soln is red.

Turmeric can be further confirmed by its behavior with H<sub>3</sub>BO<sub>3</sub>. Test as follows: Shake portion of original ether ext with equal vol. 70% alcohol; add 1/10 vol. HCl, mix, and divide soln equally into 2 test tubes. To one tube add few crystals H<sub>3</sub>BO<sub>3</sub> and shake. Use other tube as control. In presence of turmeric, red soln is produced after short time.

(c) To sep. and identify saffron and the orange synthetic dyes, dil. isoamyl alcohol ext with 2 vols pet ether and ext the mixed dyes with several 10 mL portions H<sub>2</sub>O. To small portion of this aq. ext. add 1/10 vol. HOAc and few mg dry *Na hyposulfite* to reduce all the azo dyes. This treatment will not affect saffron, which can then be re-extd with isoamyl alcohol. After washing solv. repeatedly with small portions of H<sub>2</sub>O (to remove decomposition products), evap. to dryness, and confirm presence of saffron by spot tests. Examine remainder of color soln as in Chap. 34.

#### 14.155 Rapid Method for Tartrazine (55)

Place 800 mL cold H<sub>2</sub>O and 5 mL NH<sub>4</sub>OH in 1 L erlenmeyer and add 200 g unground sample. Stopper flask and shake at intervals; 3–4 hr is usually enough time to disintegrate material. Use glass rod to dislodge material caking on bottom. Centrf. and decant clear supernate into 1 L flask. Add soln of 50 g MgSO<sub>4</sub>·7H<sub>2</sub>O dissolved in 100 mL H<sub>2</sub>O, 10 mL 12% *silicotungstic acid soln*, and 10 mL HCl; shake well, and let stand 1 hr. (This treatment will ppt almost all protein.)

Centrf., decant clear soln into container, and examine as in Chap. 34.

#### Carotenoids (56)

(Applicable only to detn of carotenoids added for coloring purposes)

#### 14.156

#### Reagents

(a) *Alcoholic potassium hydroxide soln*.—Dissolve 10 g KOH in 100 mL alcohol by warming on steam bath.

(b) *Methanol*.—92%. 8 mL H<sub>2</sub>O + 92 mL absolute MeOH.

(c) *Adsorption mixture*.—Mix equal portions by vol. of activated magnesia (Micron brand No. 2641, 2642, or Adsorptive Magnesia No. S-120, Fisher Scientific Co.) and diat. earth (Hyflo Super-Cel, Johns-Manville Products Corp.).

(d) *Carotene std soln*.—20 mg/L. Dissolve 100 mg *natural mixt. of α- and β-carotene* in 5–6 mL CS<sub>2</sub>, add 35–40 mL absolute alcohol, cool in refrigerator ca 1 hr to ensure max. crystn, and filter on *hard* paper. Dissolve carotene crystals in 5–6 mL CS<sub>2</sub>, add 40 mL pet ether, refrigerate as before, filter on *hard* paper, and dry crystals in vac. desiccator 1 hr.

Accurately weigh 20 mg purified crystals and wash with 20 mL absolute ether into 1 L g-s vol. flask. Continue to wash with pet ether, and dil. to vol. by adding pet ether as soon as carotene dissolves completely.

#### 14.157

#### Preparation of Standard Curve

Dil. 0.0, 1.25, 2.50, 3.75, 5.00, 6.25, 7.5, 8.75, and 10.00 mL carotene std soln to 250 mL with pet ether. (Concns 0.0, 0.10, 0.20, 0.30, 0.40, 0.50, 0.60, 0.70, and 0.80 mg/L.) Read solns at 436 nm in spectrophtr or in photometer. Obtain line of best fit for data by method of least sqs, item (24), *Definitions of Terms and Explanatory Notes*. In applying this method, let *x* represent scale reading and *y*, concn in mg/L.

Stdze on same day stock soln is prepd.

#### 14.158

#### Preparation of Sample

Grind macaroni and noodles to as near flour fineness as possible in ordinary coffee-type mill. (Products contg egg give no difficulty, but plain macaroni products require several grindings.) Take care not to set mill too tight, as enough heat may be generated to damage pigments.

#### 14.159

#### Determination of Total Carotenoids and Carotene

Weigh 20 g flour, semolina, or macaroni, or 10 g egg noodles, or 2 g egg yolk into 125 mL erlenmeyer. Add 50 mL alc. KOH soln and boil on steam bath 30 min under reflux condenser. Occasionally rotate flask but be as careful as possible to keep sample from collecting on sides of flask. Remove flask and cool to room temp. Filter thru buchner-type medium fritted glass filter into 250 mL suction flask, using suction, transferring most of material with few mL alcohol from wash bottle. Turn off suction, rinse flask with 25 mL ether, pour rinsing onto glass filter, and stir material with rod to let ether come in contact with all portions. Filter, and repeat this operation twice.

Transfer filtrate to 250 mL g-s separator and rinse with ca 25 mL ether, disregarding soapy material in flask. Add 175 mL H<sub>2</sub>O, carefully invert, and rotate several times. When layers sep., remove lower aq.-alcohol layer and ext this layer again with 25 mL ether. Discard lower layer and add the ether to original ether soln. Wash ether by pouring 50 mL H<sub>2</sub>O thru it. After layers sep., withdraw aq. layer and discard. Add 50 mL pet ether to ether soln, and wash with five 50 mL portions H<sub>2</sub>O, carefully inverting and rotating separator. Discard all aq. layers (slight emulsions usually clear in few min but may be discarded, especially if there is no significant yellow tinge).

Transfer ether-pet ether mixt. to 250 mL distn flask, rinsing separator with pet ether; place flask in beaker of H<sub>2</sub>O at 45–50°. Stopper flask, connect side arm with vac., and conc. to ca 5 mL to remove ether. Filter thru Allihn-type adsorption tube with coarse fritted glass plate contg ca 3 mm layer anhyd. powd Na<sub>2</sub>SO<sub>4</sub>, or thru 5.5–7.0 cm paper half filled with the Na<sub>2</sub>SO<sub>4</sub> (use small, long-stem funnel reaching thru neck of flask) into 25 mL vol. flask. Dil. to vol. with pet ether used to rinse distn flask and which has been passed portionwise thru the filter contg Na<sub>2</sub>SO<sub>4</sub>, and mix by inverting few times. Transfer to 1 cm absorption cell and read *A* at 436 nm in spectrophtr, making ≥3 readings. From av. reading, calc. total carotenoid pigment in ppm from std curve. If pure carotene is not available for stdzn, multiply *A* by 64.2 for yolk, 13.05 for noodles, or 6.52 for semolina and macaroni.

#### 14.160

#### *Separation of Carotene from Xanthophylls*

(a) *Carotene by phase separation.*—Quant. transfer all soln from cell and vol. flask to 125 mL separator, rinse with pet ether, and dil. to ca 100 mL. Add 15 mL 92% MeOH, shake moderately ca 2 min by hand or 10 min on mech. shaker, and let separator stand in upright position ca 1 min until layers sep. Decant lower layer contg xanthophyll and repeat extns 5 more times or until aq. MeOH layer is nearly colorless for semolina. (Eight extns are generally enough for noodles but higher than normal egg content may require 10 extns.) Examine final MeOH layer recovered in test tube over white background to be sure soln is nearly colorless.

Wash pet ether with 25 mL H<sub>2</sub>O, inverting separator several times; discard aq. layer and repeat twice more. Filter pet ether thru Allihn-type adsorption tube contg 6 mm layer of anhyd. powd Na<sub>2</sub>SO<sub>4</sub>, or thru 9 cm paper half filled with the Na<sub>2</sub>SO<sub>4</sub>, into 250 mL distn flask, washing color from filter with pet ether. Conc. to 5 mL by vac. as in 14.159 and transfer to 10 mL vol. flask, using very small portions of pet ether; dil. to vol., mix by inverting, and read *A* in spectrophtr as in 14.159. Calc. carotene in ppm from std curve. If pure carotene is not available for stdzn, multiply *A* by 5.22 for noodles, or by 2.61 for semolina.

(b) *Carotene by chromatographic separation.*—Prep. column in adsorption tube ca 18 mm od × 240 mm with ca 5 cm tip inserted thru rubber stopper. Loosely plug with small pad of cotton, place in 250 mL suction flask, and turn on suction. Add adsorption mixt., 14.156(c), thru funnel in small amts from spatula to ht of ca 11 cm; pack column by pressing down (*only once after all this mixt. has been added*) with cork stopper, just fitting the tube, on end of rod. Place 1–2 cm anhyd. powd Na<sub>2</sub>SO<sub>4</sub> on top.

Quant. transfer all soln from cell and vol. flask to 250 mL distn flask, and conc. as in 14.159 to ca 5 mL, continuously applying suction to flask. Transfer to prepd column and rinse with four ca 5 mL portions pet ether to remove all color. Finally rinse down sides of tube with few mL pet ether. After few drops have come thru column, change to another 250 mL suction flask. When nearly all pet ether is down to Na<sub>2</sub>SO<sub>4</sub> layer, add 50 mL

pet ether-acetone mixt. (9+1) to wash thru carotene. When all this solv. has passed thru Na<sub>2</sub>SO<sub>4</sub>, turn off suction. (Keep top of column covered with solv. during entire operation.) Transfer carotene soln (which should be only few mL) to 10 mL vol. flask, using very small portions of pet ether, dil. to vol. with pet ether, and mix by inverting. Read as in (a) and calc. in ppm. (These solns should be read on same day as extn.)

# 15. Coffee and Tea

## GREEN COFFEE

### 15.001 Macroscopic Examination—Procedure

Macroscopic examination usually shows presence of excessive amts of blank and blighted coffee beans, coffee hulls, stones, and other foreign matter. Sep. these by hand picking and det. % by wt.

### 15.002 Coloring Matters—Procedure

Vigorously shake  $\geq 100$  g sample with cold  $H_2O$  or 70% alcohol. Strain thru coarse sieve and let settle. Identify sol. colors in soln and insol. pigments in sediments as in Chap. 34.

### 15.003 Caffeine (1)—Official First Action

Grind sample to pass No. 40 sieve. Use coffee grinder or large high-speed blender, and keep sample cold with solid  $CO_2$  during grinding to avoid pastiness. Proceed as in 15.023 or 15.024.

### Chlorogenic Acid (2)—Official First Action

#### 15.004

#### Reagents

(a) *Basic lead acetate soln.*—Sp gr 1.25. Soln 31.178(a) may be used, or prep. soln from dry powder or Horne's Dry Lead.

(b) *Chlorogenic acid.*—Prep. from green coffee as in JAOAC 40, 350(1957). Available from ICN-K&K Laboratories, Cat. No. 2172. Mp after drying in vac. over efficient desiccant is 207–209°;  $\alpha$  is  $\geq 52.0$ .

#### 15.005

#### Preparation of Sample Solution

Weigh 0.7 g ground sample, 15.003, into 50 mL centr. tube. Add 25 mL pet ether, mix thoroly, centr., and decant supernate. Repeat twice. Dry residue in gentle stream of air until odor can no longer be detected. Transfer to 750 mL erlenmeyer with small amt of  $H_2O$ . Add 400 mL boiling  $H_2O$ , reheat quickly to boiling, and continue to boil gently exactly 15 min; then cool quickly to room temp. under tap. During boiling, swirl frequently to keep coffee submerged in soln. Transfer to 500 mL vol. flask and dil. to vol. Filter thru retentive paper, discarding first 25–50 mL filtrate. If filtrate is more than faintly cloudy, refilter thru fine porosity fritted glass filter, using suction. Do not use filter aids.

#### 15.006

#### Determination

Transfer 10 mL filtrate to 100 mL vol. flask and dil. to vol. with  $H_2O$ . Det  $A$  at 324 nm against  $H_2O$ . Transfer 100 mL sample soln to 200 mL Pyrex vol. flask or Kohlrausch flask. Add 2 mL *satd KOAc* soln and 10 mL basic  $Pb(OAc)_2$  soln with swirling. Place flask in boiling  $H_2O$  bath 5 min, swirling occasionally. Remove, cool under tap, and place in ice- $H_2O$  bath. Stir mech. 1 hr, using glass rod with paddle-shaped blade at lower end reaching bottom of flask, with flask immersed in bath. Remove, wash down stirrer, warm to room temp., and dil. to vol. with  $H_2O$ . Filter thru fluted paper, discarding first 25–50 mL filtrate. Immediately det.  $A$  of soln at 324 nm. Clean cells carefully after each use of  $Pb$ -treated solns because  $PbCO_3$  slowly accumulates on optical surfaces.

From std curve det. (1) apparent concn of chlorogenic acid in soln taken for  $A$  measurement without  $Pb$  treatment ( $C_0$ ); (2) apparent concn in filtrate after  $Pb$  treatment ( $C_1$ ). From latter

value subtract 0.00045 mg/mL to correct for solubility of  $Pb$  chlorogenate.

$$\text{Calc. corrected concn} = C_0 - [(C_1 - 0.00045)/5].$$

#### 15.007

#### Preparation of Standard Curve

Weigh 40.0 mg dried chlorogenic acid, transfer to 500 mL vol. flask, dissolve, and dil. to vol. with  $H_2O$ . Prep. series of stds by transferring 5, 10, 15, and 20 mL aliquots to 100 mL vol. flasks and dilg to vol. Det.  $A$  at 324 nm of each soln against  $H_2O$ . Plot concn of chlorogenic acid in mg/mL against  $A$ .

## ROASTED COFFEE

### 15.008 Macroscopic Examination—Procedure

Pick out and microscopically identify artificial coffee beans, apparent from their regular form, and roasted legumes and lumps of chicory in whole roasted coffee. For ground coffee, sprinkle some of sample on cold  $H_2O$  and stir lightly. Fragments of pure coffee float, if not overroasted, while fragments of chicory, legumes, cereals, etc., sink immediately, chicory coloring the  $H_2O$  decidedly brown. In all cases use microscopic examination to identify particles that sink.

### 15.009 Preparation of Sample—Official First Action

Grind sample to pass No. 30 sieve and store in tightly stoppered bottle.

### Loss on Drying (3)—Official Final Action

#### 15.010

#### Apparatus

(a) *Aluminum dish.*—Diam. ca 70 mm, ht ca 30 mm; with close-fitting cover.

(b) *Desiccator.*—See 14.002(b).

(c) *Vacuum oven.*—See 14.002(c).

#### 15.011

#### Determination

Sample directly without grinding. Accurately weigh ca 5 g well mixed sample in dish previously dried at 98–100°, cooled in desiccator, and weighed with cover soon after attaining room temp. Place in oven, lean cover against dish, and heat to const wt (ca 5.5 hr) at 98–100° at pressure  $\leq 25$  mm Hg. During heating admit slow current of air (ca 2 bubbles/sec thru  $H_2SO_4$ ) into oven. Carefully admit dry air into oven to bring to atm. pressure. Cover dish, transfer to desiccator, and weigh soon after room temp. is attained. Report % loss in wt.

### ISO Method (4)—Official First Action

(Applicable to instant coffees)

#### 15.012

#### Apparatus

(a) *Vacuum oven.*—Elec. heated with adjustable temp. so that temp. of shelves is maintained at  $70 \pm 1^\circ$ . During operation, vac. must be maintained at max. of 5000 N/m<sup>2</sup> (Pa) (37.5 mm Hg) by vac. pump, with air admitted thru drying train consisting of 2 gas washing bottles contg glycerol connected to 2 drying towers in series contg  $P_2O_5$  or indicating silica gel connected to oven.

(b) *Drying dishes*.—Glass or Al with close fitting slip on lids, 50 mm diam. and 20–30 mm high.

**15.013****Determination**

(Instant coffees are very hygroscopic. Work rapidly to minimize exposure to atmosphere.)

Dry empty dishes and lids in convection oven 1 hr at 100–105°. Cool in desiccator over indicating silica gel and weigh. Place ca 3 g sample in dish, spread uniformly over bottom, cover, and reweigh. If series of samples are to be run, replace in desiccator until all samples are weighed.

Remove lid and place dish and lid in oven. Close oven and reduce pressure slowly ( $\geq 2$  min) to  $5000 \pm 1000$  N/m<sup>2</sup> (37.5 mm). Dry  $16 \pm 0.5$  hr at shelf temp. of  $70 \pm 1^\circ$  with air admitted at rate of 1 bubble/sec. Then close valve to pump and admit air slowly ( $\geq 2$  min) into oven. Open oven, replace lid on dish, place in desiccator, cool, and weigh.

$$\text{Loss on drying/100 g} = (M_1 - M_2) \times 100 / (M_1 - M_0),$$

where  $M_0$  = wt (g) empty dish and lid;  $M_1$  = wt (g) dish, lid, and sample before drying; and  $M_2$  = wt (g) dish, lid, and sample after drying.

**15.014 Soluble Solids—Official Final Action****European Decaffeination Association Method (5)**

Weigh 10 g sample, **15.009**, into 500 mL erlenmeyer. Place 20 cm glass stirring rod into flask, add 200 mL H<sub>2</sub>O, and weigh. Bring to bp while stirring and boil exactly 5 min. Cool, reweigh, and add H<sub>2</sub>O to bring wt back to original. Filter. Evap. 25 mL filtrate. Dry in 105° air oven, and weigh residue. Continue drying to const wt.

**15.015 Ash—Official Final Action**

Proceed as in **31.012** or **31.013**, using sample prep'd as in **15.009**.

**15.016 Soluble and Insoluble Ash—Official Final Action**

Proceed as in **31.015**, using the ash obtained in **15.015**.

**15.017 Alkalinity of Soluble Ash—Official Final Action**

Proceed as in **31.016**, using the filtrate obtained in **15.016**.

**15.018 Ash Insoluble in Acid—Official Final Action**

Proceed as in **30.008**, using the ash obtained in **15.015** or H<sub>2</sub>O-insol. ash obtained in **15.016**.

**15.019 Soluble Phosphorus in Ash—Official Final Action**

Proceed as in **7.121** or **8.033**, using soln obtained in **15.016**.

**15.020 Insoluble Phosphorus in Ash—Official Final Action**

Boil insol. ash, **15.016**, with 25 mL HCl (1+2), filter, wash thoroly with hot H<sub>2</sub>O, and det. P<sub>2</sub>O<sub>5</sub> in combined filtrate and washings as in **7.119** or **8.033**.

**15.021 Chlorides—Official Final Action**

See **3.071–3.072**.

**Caffeine****15.022 ★ Power-Chesnut Method (6) ★ Official Final Action**

(Not applicable to coffee exts. *Caution:* See **51.011** and **51.056**.)

See **14.019**, 10th ed.

**15.023 Bailey-Andrew Method—Official Final Action**

Proceed as in **15.051**, using 10 g regular coffee or 5 g regular sol. coffee.

**15.024 Micro Bailey-Andrew Method (7) Official Final Action**

Weigh 2 g regular coffee or 1 g regular instant coffee, add 5 g powd MgO, and transfer to weighed 500 mL erlenmeyer. Add ca 150–200 mL H<sub>2</sub>O, heat to boiling, and boil 45 min, shaking occasionally. Add H<sub>2</sub>O, when necessary, to prevent frothing (final wt of H<sub>2</sub>O must be 100 g). Cool to room temp. Make mixt. to tare wt + 105 g + sample wt.

Filter directly into 50 mL graduate until exactly 50 mL soln (equiv. to  $\frac{1}{2}$  sample wt) is obtained. Transfer soln to 125 mL separator. Wash graduate with 2 mL H<sub>2</sub>O and add washing to separator. Add 4 mL H<sub>2</sub>SO<sub>4</sub> (1+9). Ext with five 10 mL portions CHCl<sub>3</sub>, shaking vigorously 1 min for each extn. Let emulsion break; then drain CHCl<sub>3</sub> into 125 mL separator. Add 5 mL 1% KOH soln. Shake vigorously 1 min, let emulsion break, and drain CHCl<sub>3</sub> thru cotton plug into 100 mL Kjeldahl flask. Ext KOH soln with 5 mL CHCl<sub>3</sub> and add to Kjeldahl flask. To digestion flasks add  $1.9 \pm 0.1$  g K<sub>2</sub>SO<sub>4</sub>,  $40 \pm 10$  mg HgO, and  $2.0 \pm 0.1$  mL H<sub>2</sub>SO<sub>4</sub>. Add boiling chips and rinse down neck of flask with 3 mL CHCl<sub>3</sub>. Place flask on digestion rack and proceed as in **47.023**. 1 mL 0.02N acid = 0.971 mg caffeine.

**Chromatographic-Spectrophotometric Method (7) Official First Action**

(Applicable to regular and decaffeinated coffee)

**15.025****Reagents and Apparatus**

(a) *Caffeine std solns.*—10, 20, and 30  $\mu$ g caffeine/mL. Accurately weigh 100 mg caffeine (USP, anhyd.) into 100 mL vol. flask, dissolve in CHCl<sub>3</sub>, and dil. to vol. with CHCl<sub>3</sub>. Dil. 10 mL aliquot of this soln to 100 mL with CHCl<sub>3</sub>. Further dil. 10, 20, and 15 mL aliquots to 100, 100, and 50 mL, resp., with CHCl<sub>3</sub> to obtain std solns of 10, 20, and 30  $\mu$ g/mL.

(b) *Recording spectrophotometer.*—To record 350–250 nm range, with matched 1 cm cells.

**15.026****Preparation of Sample**

(a) *Green and roasted coffee.*—Accurately weigh ca 1 g ground sample, transfer to 100 mL beaker, add 5 mL NH<sub>4</sub>OH (1+2), and warm on boiling H<sub>2</sub>O bath 2 min. Cool, transfer to 100 mL vol. flask, and dil. to vol. with H<sub>2</sub>O. To 5 mL aliquot of the turbid soln add 6 g Celite 545 and mix carefully.

(b) *Decaffeinated green and roasted coffee.*—Accurately weigh ca 1 g ground sample. Transfer to 100 mL beaker, add 5 mL NH<sub>4</sub>OH (1+2), and warm on boiling H<sub>2</sub>O bath 2 min. Add 6 g Celite 545 and mix carefully.

(c) *Soluble coffee.*—Proceed as in (a), except use 0.5 g sample and 3 mL aliquot.

(d) *Decaffeinated soluble coffee.*—Proceed as in (b), except use 0.5 g sample.

**15.027****Preparation of Columns**

(a) *Acid column.*—Place fine glass wool plug in base of 25 × 250 mm tube. Add 3 mL 4N H<sub>2</sub>SO<sub>4</sub> to 3.0 g Celite 545 and mix well by kneading with spatula blade. Transfer to tube and tamp, using gentle pressure, to uniform mass. Place small glass wool wad above surface.

(b) *Basic column.*—*Layer I.*—Mix 3 g Celite 545 and 2 mL 2N

★ Surplus method—see inside front cover.

NaOH, and place in 25 × 250 mm tube over glass wool plug as in (a). *Layer II.*—Transfer sample plus Celite mixt. from 15.026, in ca 2 g portions, to tube directly over Layer I, tamping before adding next portion of sample, until homogeneous and compact layer is obtained. Dry-wash beaker with ca 1 g Celite 545, transfer to tube, and tamp to uniform mass. Dry-wash beaker with wad of glass wool and transfer to top of basic column.

**15.028****Determination**

Mount basic column above acid column. Pass 150 mL H<sub>2</sub>O-satd ether sequentially thru basic column to acid column and discard ether. Then pass 50 mL H<sub>2</sub>O-satd ether thru acid column and discard ether. Place 50 mL vol. flask under acid column. Pass 48 mL H<sub>2</sub>O-satd CHCl<sub>3</sub> thru acid column, washing tip of basic column with first portions. Dil. contents of vol. flask to vol. with H<sub>2</sub>O-satd CHCl<sub>3</sub>, mix, and read *A* at 276 against H<sub>2</sub>O-satd CHCl<sub>3</sub> blank, by scanning from 350 to 250 nm.

Det. *A* of stds and calc. *a* (see Definitions of Terms and Explanatory Notes, Item 23(c)) at 276 nm for spectrophtr used, and check occasionally. Calc. caffeine content of samples from av. *a*.

**15.029 Chlorogenic Acid (2)—Official First Action**

(a) *Roasted coffee.*—Weigh 1 g ground sample, 15.009, transfer to 750 mL erlenmeyer, and proceed as in 15.005, beginning "Add 400 mL boiling H<sub>2</sub>O, . . ."

(b) *Instant coffee.*—Weigh 0.35 g sample, transfer to 500 mL vol. flask, dil. to vol., and proceed as in 15.006.

**15.030 Crude Fiber—Official Final Action**

Proceed as in 7.065, using sample prepd as in 15.009.

**15.031 Starch—Official Final Action**

Ext 5 g prepd sample, 15.009, on hardened filter with five 10 mL portions ether, and wash with small portions alcohol until total of 200 mL has passed thru. Transfer residue from paper to beaker with 50 mL H<sub>2</sub>O and proceed as in 31.101, beginning with third par.

**15.032 Sugars (8)—Official Final Action**

Weigh 10 g prepd sample, 15.009, into 250 mL vol. flask, add 1 g powd *NH<sub>4</sub>NaHPO<sub>4</sub>*, and proceed as in 7.079, par. 1 and 2, beginning with addn of 50% alcohol, and 31.038. Det. Cu in Cu<sub>2</sub>O ppt either volumetrically, 31.041, or electrolytically, 31.044.

**15.033 Petroleum Ether Extract—Official Final Action**

(Caution: See 51.011, 51.039, and 51.073.)

Dry 2 g prepd sample, 15.009, at 100°, ext with pet ether (bp 30–60°) 16 hr, evap. solv., dry residue at 100°, cool, and weigh.

**15.034 Total Acidity—Official Final Action**

Treat 10 g prepd sample, 15.003 or 15.009, in erlenmeyer with 75 mL 80% alcohol, stopper, and let stand 16 hr, shaking occasionally. Filter, transfer aliquot of filtrate (25 mL for green coffee, 10 mL for roasted coffee) to beaker, dil. to ca 100 mL with H<sub>2</sub>O, and titr. with 0.1*N* alkali, using phthln. Express result as mL 0.1*N* alkali required to neutze acidity of 100 g sample.

**15.035 Coating and Glazing Substances Procedure**

(Caution: See 51.011, 51.039, and 51.073.)

(a) *Sugar and dextrin.*—To 100 g whole coffee in beaker, add

exactly 300 mL H<sub>2</sub>O, stir, and let stand 5 min, stirring frequently. Filter thru dry paper and carefully add dry Pb(OAc)<sub>2</sub> to filtrate until pptn is complete, avoiding excess reagent. Filter thru dry filter and remove Pb from filtrate by adding slight excess of dry, powd K<sub>2</sub>C<sub>2</sub>O<sub>4</sub>. Filter thru dry filter and det. reducing sugars as invert sugar in 50 mL of the filtrate as in 31.038.

Invert 75 mL aliquot filtrate as in 31.026(b). Cool, nearly neutze with NaOH soln (1+1), dil. to 100 mL, and det. reducing sugars as invert sugar in resulting soln as in 31.038.

Measure 100 mL aliquot filtrate into 200 mL vol. flask, add 10 mL HCl (sp gr 1.125), and hydrolyze as in 8.019. Cool, neutze with NaOH soln (1+1), dil. to vol., filter thru dry filter, and det. reducing sugars as invert sugar in 50 mL filtrate as in 31.038.

Calc. reducing sugars in each instance to % by wt original coffee. Calc. sucrose from reducing sugars before and after inversion as in 31.031, and calc. dextrin as follows: Subtract reducing sugars after inversion from reducing sugars after hydrolysis and multiply difference by factor 0.86.

In some instances presence of sucrose in H<sub>2</sub>O ext may be verified by polarization. Presence of dextrin in H<sub>2</sub>O ext may be verified by polarization as in 31.033, and by erythrodestrin test, (b).

(b) *Erythrodestrin test for commercial glucose.*—To aq. ext, (a), prior to clarification with Pb(OAc)<sub>2</sub>, add few mL I soln (1 g I, 3 g KI, 50 mL H<sub>2</sub>O). In presence of com. glucose, soln turns red or violet, depth and character of color depending upon quality and nature of glucose used. If amt of glucose is very small, ppt dextrin that may be present by adding several vols alcohol. Let ppt settle (do not filter), decant liq., dissolve residue of dextrans in hot H<sub>2</sub>O, cool, and apply I test. Neg. result does not prove absence of com. glucose, because some glucose, especially of high conversion, does not give reaction with I.

(c) *Egg albumen and gelatin.*—Add 500 mL H<sub>2</sub>O to 100 g whole coffee and let stand 5 min, stirring frequently. Filter and treat sep. portions of filtrate with (1) 5% soln of tannic acid, and (2) Millon reagent, 7.125(g). Boil third portion of filtrate. In presence of egg albumen more or less heavy ppt will form in each case.

As confirmatory test, treat aliquot of filtrate with excess tannic acid soln, add little NaCl if necessary to flocculate ppt, filter, and without washing, insert paper and contents into Kjeldahl flask, and det. N. By this method coffee not coated with albumen or gelatin yields <10 mg N/100 g sample.

(d) *Fats and waxes.*—Treat 100–200 g coffee beans 10 min with low-boiling pet ether, pour off pet ether, and repeat process. Filter combined ext, evap., and det. refractive index and saponification number of the residue as in 28.007 and 28.026.

**15.036 Chicory Infusion—Procedure**

Cover 100–150 g whole coffee with H<sub>2</sub>O, let soak 2–3 min, stirring frequently, and drain aq. washings thru coarse sieve. Wash coffee on sieve with ca 100 mL H<sub>2</sub>O and centr. combined washings. Decant clear liq. from sediment, drain sediment almost dry on filter paper, mount in chloral hydrate soln, 30.029(b), and examine microscopically for chicory.

**TEA****15.037 Preparation of Sample—Official Final Action**

Grind sample to pass No. 30 sieve.

**15.038 Moisture—Official Final Action**

See 7.003.

**15.039 Water Extract (9)—Official Final Action**

To 2 g ground sample in 500 mL vol. flask, add 200 mL hot H<sub>2</sub>O and boil over low flame 1 hr, rotating occasionally. Close flask with rubber stopper thru which passes tube 75 cm long for condenser. Boil very slowly so that no steam escapes from top of air condenser. Cool, dil. to vol., mix thoroly, and filter thru dry paper. Transfer 50 mL aliquot to weighed dish, and evap. to dryness on steam bath. Place in oven, heat 1 hr at 100°, cool, and weigh.

**15.040 Ash—Official Final Action**

See 31.012 or 31.013.

**15.041 Soluble and Insoluble Ash—Official Final Action**

Proceed as in 31.015, using the ash obtained in 15.040.

**15.042 Alkalinity of Soluble Ash—Official Final Action**

Proceed as in 31.016, using the filtrate obtained in 15.041.

**15.043 Alkalinity of Insoluble Ash—Official Final Action**

Proceed as in 31.017, using insol. ash obtained in 15.041.

**15.044 Ash Insoluble in Acid—Official Final Action**

Proceed as in 30.008, using total ash obtained in 15.040, or insol. residue obtained in 15.041.

**15.045 Soluble Phosphorus in Ash—Official Final Action**

Proceed as in 7.119 or 8.033, using soln of sol. ash obtained in 15.042.

**15.046 Insoluble Phosphorus in Ash—Official Final Action**

Proceed as in 7.119 or 8.033, using soln obtained in 15.043.

**15.047 Petroleum Ether Extract—Official Final Action**

See 15.033.

**15.048 Protein—Official Final Action**

Det. N as in 2.057. Protein = (% total N - % N present as caffeine) × 6.25.

**15.049 Crude Fiber—Official Final Action**

See 7.065.

**Caffeine****15.050 ★ Power-Chesnut Method (10) ★  
Official Final Action**

See 15.022.

**15.051 Modified Bailey-Andrew Method (11)  
Official Final Action**

Weigh 5 g prepd sample, 15.037, into weighed 1 L erlenmeyer. Add ca 500 mL H<sub>2</sub>O, swirl, and heat to bp. Add 10 g heavy MgO. Boil gently over low flame 2 hr with occasional shaking. Add H<sub>2</sub>O to prevent frothing and to wash down sides of flask. Cool, and make to wt with H<sub>2</sub>O (tare wt + 510 g + wt sample). Filter, collect 200 mL clear filtrate (equiv. to 0.4 sample wt), add 20 mL H<sub>2</sub>SO<sub>4</sub> (1+9), and transfer to 500 mL separator. Shake 6 times with CHCl<sub>3</sub>, using 25, 20, 15, 10, 10, and 10 mL portions. Treat

combined exts with 5 mL 1% KOH soln; when liqs sep. completely, drain CHCl<sub>3</sub> layer into Kjeldahl flask. Wash alk. soln in separator with two 10 mL portions CHCl<sub>3</sub> and combine washings with remaining bulk of ext. Evap. or distil off the CHCl<sub>3</sub> to <25 mL, and proceed as in 2.057. 1 mL 0.1N H<sub>2</sub>SO<sub>4</sub> = 4.85 mg anhyd. caffeine.

**Ultraviolet Spectrophotometric and  
Gas-Liquid Chromatographic Methods  
for "Instant Tea" (12)—Official Final Action**

(First action for leaf tea)

**15.052****Reagents**

(a) *Caffeine std solns.*—(1) *Soln No. 1.*—500 µg/mL. Accurately weigh ca 100 mg caffeine, USP; dissolve and dil. to 200 mL with CHCl<sub>3</sub> in vol. flask. (2) *Soln No. 2.*—10 µg/mL. Pipet 20 mL *Soln No. 1* into 100 mL vol. flask and dil. to vol. with CHCl<sub>3</sub>; dil. 10.0 mL of this soln to 100 mL with CHCl<sub>3</sub>.

(b) *Pentobarbital internal std soln.*—2 mg/mL. Accurately weigh ca 200 mg pentobarbital; dissolve and dil. to 100 mL with alcohol in vol. flask.

(c) *GLC working std soln.*—250 µg caffeine and 1 mg pentobarbital/mL. Pipet equal vols caffeine std *Soln No. 1* and pentobarbital internal std into g-s flask and mix thoroly. Prep. fresh daily.

**15.053****Apparatus**

(a) *Gas chromatograph.*—Equipped with thermionic KCl detector. Typical operating conditions: Temps (°): column 190, detector 220, and injector 220; N carrier gas. Inject 5 µL GLC working std soln and record chromatogram. Adjust attenuation and sensitivity ( $1 \times 10^{-8}$  AFS), if necessary, to bring peaks to ca half-scale deflection. Adjust flow rate of N so that caffeine is eluted in ca 7 min.

(b) *Gas chromatographic column.*—Glass, 1.8 m (6') × 4 mm id packed with 10% DC-200 oil on 80–100 mesh Gas-Chrom Q (Applied Science Laboratories, Inc., precoated, or equiv.). Condition column >24 hr at 250–260° (with N flow of 100±20 mL/min).

(c) *Recording spectrophotometer.*—350–250 nm range with matched 1 cm cells.

(d) *Chromatographic tubes.*—Glass, 25 × 250 mm.

**15.054****Preparation of Sample**

(a) *Leaf tea.*—Grind sample in high-speed blender or other suitable device to pass No. 30 or 40 sieve. Accurately weigh ca 1 g tea into 100 mL beaker, add ca 40 mL NH<sub>4</sub>OH (1+2), and heat 5 min on steam bath. Transfer quant. to 100 mL vol. flask, cool, and dil. to vol. with NH<sub>4</sub>OH (1+2). Transfer 5.0 mL aliquot to 6 g Celite 545 (acid-washed) in 100 mL beaker and proceed as in 15.027.

(b) *Instant tea.*—Place 0.5 g sample in 100 mL beaker and continue as in 15.027.

**15.055****Preparation of Columns and Sample Solution**

Prep columns as in 15.027(a) and (b). Isolate caffeine as in 15.028, dil. to 50 mL, and proceed as in 15.056.

**15.056****Spectrophotometric Determination**

Transfer 10.0 mL aliquot leaf tea sample soln to 50 mL vol. flask and dil. to vol. with CHCl<sub>3</sub>. Transfer 10.0 mL aliquot instant tea sample soln to 100 mL vol. flask, dil. to vol. with CHCl<sub>3</sub>, and further dil. 20.0 mL aliquot to 100 mL with CHCl<sub>3</sub>. Det. A at 276

★ Surplus method—see inside front cover.

nm on recording spectrophtr against  $\text{CHCl}_3$  as ref. Compare with  $A$  of std caffeine *Soln No. 2* ( $10 \mu\text{g/mL}$ ).

$$\% \text{ Caffeine} = (A/A') \times (C'/C) \times 100$$

where  $A$  and  $A'$  refer to sample and std, resp., and  $C$  and  $C'$  refer to sample and std concns, resp.

**15.057****Gas Chromatographic Determination**

Complete detn within 1 day. Pipet equal vols pentobarbital internal std soln and concd sample soln into g-s flask and mix (assay soln). Inject  $5 \mu\text{L}$  working std soln and record chromatogram. Inject  $5 \mu\text{L}$  assay soln and record chromatogram. Measure ht of each peak. Let  $P_s$  = ht of std peak of GLC working std soln;  $P_u$  = ht of sample peak of assay soln;  $I_s$  = ht of internal std peak of std;  $I_u$  = ht of internal std peak of assay soln;  $C_s$  = mg caffeine/mL in GLC working std soln;  $C_u$  = mg sample/mL.

$$\% \text{ Caffeine in sample} = (P_u \times I_s \times C_s \times 100) / (P_s \times I_u \times C_u).$$

**15.058 Copper and Nickel—Official First Action**

See 25.044–25.048.

## 16. Dairy Products

### SAMPLING (1)—OFFICIAL FINAL ACTION

(Prepd by a joint committee of International Dairy Federation, International Organization for Standardization, and AOAC, 1965, for the Joint FAO/WHO *Code of Principles Concerning Milk and Milk Products and Associated Standards*. Methods are intended to obtain from unit (e.g., bulk container, small retail container, individual cheese, etc.) portion (subsample) which is as representative as possible of that unit.)

#### General Instructions

##### 16.001 *Instructions of Administrative Character*

(This section is usually prescribed by specific regulatory agency. It is included for completeness.)

Sampling should be performed by authorized or sworn independent agent, properly trained in appropriate technic. Agent should be free from any infectious disease. If possible, representatives of parties concerned should be given opportunity to be present when sampling is performed.

Samples should be accompanied by report, signed by sworn or authorized sampling agent and countersigned by any witnesses present. Report should give particulars of place, date, and time of sampling; name and designation of agent and of any witnesses; precise method of sampling which is followed if this deviates from prescribed std method; nature and number of units constituting consignment together with their batch code markings, where available; number of samples duly identified as to batches from which they are drawn; and place to which the samples will be sent.

When appropriate, report should also include any relevant conditions or circumstances, e.g., condition of packages and their surroundings, temp. and humidity of atm., method of sterilization of sampling equipment, whether preservative has been added to samples, and any other special information relating to material being sampled.

Each sample should be sealed and labeled to give nature of product, identification number, and any code markings of batch from which sample has been taken, date of sampling, and name and signature of sampling agent. When necessary, addnl information may be required, for example, wt of sample and unit from which it was taken.

All samples should be taken at least in duplicate, one set being held, if necessary, in cold storage and put at disposal of second party as soon as possible. Precise method of sampling and wt or vol. of product to be taken as sample vary with nature of product and purpose for which sampling is required and are defined for each particular case.

When previously agreed between parties, take addnl sets of samples and retain for independent arbitration, if necessary. Send samples to testing laboratory immediately after sampling.

##### 16.002 *Technical Instructions*

(See sampling equipment specifications laid down for each product to be sampled.)

(a) *Sampling for chemical purposes.*—Clean and dry all equipment.

(b) *Sampling for bacteriological purposes.*—Clean and treat equipment by one of following methods: (1) Expose to hot air 2 hr at 170° (may be stored if kept under sterile conditions). (2) Autoclave 15–20 min at 120° (may be stored if kept under sterile conditions). (3) Expose to steam 1 hr at 100° (use equipment same day). (4) Immerse in H<sub>2</sub>O 1 min at 100° (use equipment

immediately). (5) Immerse in 70% alcohol and flame to burn off alcohol immediately before use. (6) Expose to hydrocarbon (propane, butane) torch flame so that all working surfaces contact flame immediately before use.

Choice of treatment depends on nature, shape, and size of equipment and on conditions of sampling. Sterilize wherever possible by method (1) or (2).

Methods (3), (4), (5), and (6) are regarded as secondary methods only.

(c) *Sampling for organoleptic purposes.*—Use equipment as in (a) or (b), or as specified for specific product. Equipment should not impart any flavor or odor to product.

##### 16.003

#### *Sample Containers*

(a) *For liquids.*—Use clean and dry containers of suitable waterproof, greaseproof material (glass, stainless metal, suitable plastic material) of quality suitable for sterilization by 16.002(b), if necessary, and of suitable shape and capacity for material to be sampled (as defined in each particular case).

Securely close containers either with suitable rubber or plastic stopper or by screw cap of metal or plastic having, if necessary, liq.-tight plastic liner which is insol., nonabsorbent, and greaseproof, and which will not influence odor, flavor, or composition of milk products.

If rubber stoppers are used, cover with nonabsorbent, flavorless material (such as suitable plastic) before pressing into sample container. Suitable plastic bags may also be used.

(b) *For solids or semisolids.*—Use clean and dry wide-mouth, cylindrical receptacles of suitable waterproof, greaseproof material (glass, stainless metal, suitable plastic material) of quality suitable for sterilization by 16.002(b), if necessary, and of capacity suited to size of sample to be taken (as defined in each particular case). Make air-tight as in (a). Suitable plastic bags may also be used.

(c) *Small retail containers.*—Contents of intact and unopened containers constitute samples.

##### 16.004

#### *Preservation of Samples*

To samples of liq. products or cheese intended for chem. analysis, suitable preservative may be added. Such preservative should not interfere with subsequent analysis. Indicate nature and amt of addn on label and in any reports.

Do not add preservatives to samples of semisolid, solid (except cheese), or dried products intended for chem. analysis. Rapidly cool and store samples in refrigerator at 0–5°. Dried milks may be kept at room temp.

Do not add preservatives to samples intended for bacteriological or organoleptic examination. Hold at 0–5°, except for condensed (conserved) milk products when sample comprises unopened hermetically sealed containers in which products are sold. Keep liq. products and butter cold. Start bacteriological examination of liq. products as soon as possible and never >24 hr after sampling.

##### 16.005

#### *Transport of Samples*

Transport samples to laboratory as quickly as possible after sampling. Take precautions to prevent, during transit, exposure to direct sunlight, or to temps <0° or >10° in case of perishable products. For samples intended for bacteriological examination, use insulated transport container capable of maintaining temp.

at 0–5°, except for samples of condensed (conserved) milk products in unopened containers, or in case of very short journeys.

Maintain samples of cheese under such conditions as to avoid sepn of fat or moisture. Maintain soft cheese at 0–5°.

#### **Sampling of Milk and Liquid Milk Products (Except Evaporated and Sweetened Condensed Milk)**

##### **16.006**

##### ***Sampling Equipment***

(a) *Plungers or agitators, necessary for mixing liquids in bulk.*—Use equipment, **16.008(a)**, of sufficient area to produce adequate agitation of product and light enough in wt for operator to be able to move it rapidly thru liq. Mix contents of large vessels by mech. stirring.

(b) *Dipper of suitable size, for collecting sample.*—When sample is required for bacteriological examination, sterilize sampling equipment as in **16.002(b)**.

##### **16.007**

##### ***Sampling Technic***

Thoroughly mix all liqs by pouring from one vessel to another, by plunging, or by mech. stirring. With large containers, continue agitation until liq. is thoroughly mixed. In case of cream, plunge sufficient number of times to ensure thoro mixing. Move submerged plunger from place to place with special care to avoid foaming, whipping, and churning. Take sample with dipper immediately after mixing. If obtaining perfect homogeneity presents difficulties, take sample from different positions of container totaling  $\geq 200$  mL.

(For addnl instructions, see **16.019** for milk and **16.144** for cream.)

#### **Sampling of Condensed Milk and Evaporated Milk**

##### **16.008**

##### ***Bulk Containers (Barrels, Drums, Etc.)***

(a) *Sampling equipment.*—Broad-bladed metal stirrer fitted with wide perforated disk at bottom and long enough to reach bottom of container.

(b) *Sampling technic.*—Use stirrer to mix contents very carefully and to scrape adhering material from sides and bottom of container. Remove 2–3 L well mixed contents to smaller receptacle, repeat stirring, and take sample  $\geq 200$  mL.

(c) *Sample containers.*—Use wide-mouth sample jars with air-tight lids.

##### **16.009**

##### ***Small Retail Containers***

Sample unit is one intact, unopened container that, whenever possible, bears manufacturer's code markings. Do not open container until just before analysis.

(For prepn of sample, see **16.167** for evapd milk and **16.181** for sweetened condensed milk.)

#### **Sampling of Dried Milk and Dried Milk Products**

(Perform sampling for bacteriological examination first, independent of other sampling, from same bulk container, whenever possible.)

##### **16.010**

##### ***Sampling for Chemical Analysis and Organoleptic Examination***

(a) *Sampling equipment.*—Use suitable clean, dry borer tube or trier of stainless steel, Al, or Al alloy.

(b) *Sampling technic.*—Pass tube steadily thru powder at even rate of penetration. When tube reaches bottom of container withdraw contents and discharge immediately into sample

container. Do not touch powder with fingers. Take  $\geq 1$  bores to make up 300–500 g samples.

(c) *Sample containers.*—Place samples in clean, dry containers, air-tight and, if required for examination, opaque. Use sample container large enough to allow mixing by shaking.

(d) Submit unopened original container of gas-packed dried milk if gas analysis is required.

##### **16.011**

##### ***Sampling for Bacteriological Examination***

Take samples for bacteriological examination, whenever possible, from same package as for chem. and organoleptic examination. Take sample for bacteriological examination first.

(a) *Sampling equipment.*—Sterilize suitable stainless steel or Al spoon or trier as in **16.002(b)(1)**, (2), (5), or (6).

(b) *Sampling technic.*—Using sterile metal implement (e.g., broad-bladed knife or spoon), remove surface layer of powder from sampling area. With another sterile spoon or trier, take sample of 50–200 g, if possible, from point near center of container. Place sample as quickly as possible into sample container, and close immediately, using aseptic precautions. In case of dispute concerning bacteriological conditions of top layer of powder in packing, take special sample from this top layer.

(c) *Sample containers.*—Place samples in clean, dry, sterile containers, preferably brown if transparent, capable of air-tight closure.

(For addnl instructions, see **16.190**.)

#### **Sampling of Butter**

##### **16.012**

##### ***Sampling Equipment***

Use butter triers long enough to pass diagonally to base of container. Use stainless steel spatulas or knives for removing portions of sample from trier. Clean and dry triers, spatulas, and knives before use, and if sampling for bacteriological purposes is required, sterilize as in **16.002(b)(4)**, (5), or (6).

##### **16.013**

##### ***Sampling Technic***

(a) *Butter in bulk.*—Take  $\geq 2$  cores of butter so that min. wt of total sample is  $\geq 200$  g. For butter in barrels, take 1 core by inserting trier diagonally thru butter from edge of barrel. Take others by inserting trier from arbitrary points of surface, vertically downward to bottom. For butter in cubes, take cores by inserting trier from top corners diagonally thru center to bottom. In both cases, make 1 complete turn and withdraw full core. Hold point of trier over mouth of sample container and immediately transfer core from trier in ca 75 mm pieces with spatula or knife. Leave plug  $\geq 25$  mm to place in hole from which core was removed. Do not include moisture adhering to outside of trier.

Clean and dry trier before each drawing. Soften butter, frozen so hard as to resist trier, by storing 24 hr at ca 10°.

(b) *Butter in pats or rolls of small size.*—Divide units weighing  $\geq 250$  g in 4, and take 2 opposite quarters. In sizes weighing  $< 250$  g take whole unit.

(For addnl instructions, see **16.203**.)

##### **16.014**

##### ***Sample Containers***

Use wide-mouth jars conforming to **16.003(b)**. Fill jar  $\geq \frac{1}{2}$  full and hermetically seal. Immediately after closure, wrap jars in paper or store in dark, if examination so requires. Do not let butter come into contact with paper or any H<sub>2</sub>O or fat absorbing or trapping surface.

## Sampling of Cheese

### 16.015

#### Sampling Equipment

(a) Cheese triers of shape and size suited to cheese to be sampled.

(b) Stainless steel knife with pointed blade.

(c) Sealing compounds.—(1) Mix by heating paraffin, beeswax, and white petrolatum (1+1+2); or (2) mix by heating white petrolatum and paraffin (1+1).

### 16.016

#### Sampling Technic

Draw enough subsamples to give total sample of  $\geq 50$  g. Use one of following technics, depending on shape, wt, type, and maturity of cheese (when choice is necessary between (a) and (b), method (a) is preferable but (b) is acceptable, especially with hard cheese of large size).

(a) *Sampling by cutting*.—Using knife with pointed blade, make 2 cuts radiating from center of cheese, if cheese has circular base, or parallel to sides if base is rectangular. Size of piece thus obtained should be such that, after removal of inedible surface layer, remaining edible portion weighs  $\geq 50$  g.

(b) *Sampling by means of trier*.—According to shape, wt, and type of cheese, use one of following sampling technics: (1) Insert trier obliquely towards center of cheese once or several times into one of flat surfaces at point  $\geq 10$  cm from edge. (2) Insert trier perpendicularly into one face and pass thru center of cheese to reach opposite face. (3) Insert trier horizontally into vertical face of cheese, midway between 2 plane faces, toward center of cheese. (4) In case of cheese transported in barrels, boxes, or other bulk containers, or cheese which is formed into large compact blocks, perform sampling by passing trier obliquely thru contents of container from top to base. (5) For large cheeses, use outer 2 cm or more of plug contg rind for closing hole made in cheese. Remainder of plug constitutes sample. Close plug holes with great care and, if possible, seal over with sealing compd, 16.015(c).

(c) *Sampling by taking entire cheese*.—Normally use for small cheese and for wrapped portions of cheese packaged in small containers. Take enough packages to have  $\geq 50$  g.

Weigh, at time of sampling, cheese sold by piece for which min. wt dry matter in unit is specified by national legislation, and state wt on label.

(d) *Sampling of cheese in brine*.—Take fragments of  $\geq 200$  g each and enough brine to cover cheese in sample container. Before analysis, place sample on filter paper 1–2 hr.

(For addnl instructions, see 16.231.)

### 16.017

#### Sample Containers

Use sample containers with air-tight closures. Immediately after sampling, place samples (plugs, sectors, entire small cheese, fragments of brine cheese) in container of suitable size and shape. Sample may be cut into pieces for insertion into container but do not compress or grind.

### 16.018

#### Treatment of Samples

In prepn of sample, whatever method of sampling is used, carefully remove only inedible surface layer of cheese, if any, such as moldy and horny portions, unless prescribed otherwise. Do not remove outer rind or crust from soft cheese sold by piece, and for which min. wt of dry matter in unit is specified by national legislation.

(For addnl instructions, see 16.232.)

## MILK

### 16.019

#### Collection of Sample—Procedure

(See also 16.001–16.007.)

Sample size necessary varies with analyses required. For usual analysis collect 250–500 mL ( $\frac{1}{2}$ –1 pt) sample; for fat detn only, collect 50–60 mL (ca 2 fl oz).

For bottled milk, collect  $\geq 1$  container as prepd for sale. Thoroughly mix bulk milk by pouring from one clean vessel into another 3 or 4 times or stir  $\geq 30$  sec with utensil reaching to bottom of container. If cream has formed, detach all of it from sides of vessel and stir until liq. is evenly emulsified or use hand homogenizer.

Place in nonabsorbent, air-tight containers and keep cold, but above freezing temp., until examined. When transporting samples, completely fill containers, stopper tightly, and identify. Tablets contg  $\text{HgCl}_2$ ,  $\text{K}_2\text{Cr}_2\text{O}_7$ , or other suitable preservative,  $\geq 0.5$  g active ingredient per tablet for each 8 fl oz (250 mL) milk, but total wt of such tablet  $\leq 1$  g, or 36% soln of  $\text{HCHO}$ , 0.1 mL (2 drops) per fl oz (30 mL), may be used unless presence of preservative is objectionable in physical or chem. tests to be made in addn to detn of fat. If phosphatase test is to be made, only  $\text{CHCl}_3$  can be used as preservative, and stoppers must be of phenol-free material such as red rubber.

### 16.020

#### Preparation of Sample—Procedure

Bring sample to ca  $20^\circ$ , mix until homogeneous by pouring into clean receptacle and back repeatedly, and promptly weigh or measure test portion. If lumps of cream do not disperse, warm sample in  $\text{H}_2\text{O}$  bath to ca  $38^\circ$  and keep mixing until homogeneous, using policeman, if necessary, to reincorporate any cream adhering to container or stopper. Where practical and fat remains dispersed, cool warmed samples to ca  $20^\circ$  before transferring test portion.

When Babcock method, 16.061, is used, adjust both fresh and composite samples to ca  $38^\circ$ , mix until homogeneous as above, and immediately pipet portions into test bottles.

### 16.021 Specific Gravity—Procedure

Det sp gr at  $15.6/15.6^\circ$  with pycnometer or std hydrometer.

### 16.022 Somatic Cell Count—Official First Action

See 46.086–46.109.

### 16.023 Acidity (2)—Official Final Action

Measure or weigh suitable amt (ca 20 mL or 20 g) sample into suitable dish and dil. with twice its vol.  $\text{CO}_2$ -free  $\text{H}_2\text{O}$ . Add 2 mL phthln, and titr. with 0.1N NaOH to first persistent pink. If measured vol. sample was used, det. its wt from sp gr of sample. Report acidity as % lactic acid by wt. (1 mL 0.1N NaOH = 0.0090 g lactic acid.) If Babcock milk pipet, 16.060(b), is used, mL 0.1N NaOH required  $\div 20$  = % acid as lactic acid.

Results may also be expressed as mL 0.1N NaOH/100 g sample.

### Citric Acid (3)—Official Final Action

### 16.024

#### Preparation of Sample

To 50 g milk in 150 mL beaker, add ca 100 mg tartaric acid and 6 mL 1N  $\text{H}_2\text{SO}_4$ , and heat on steam bath 15 min. Immediately add 3 mL 20% phosphotungstic acid soln, mix well, and return to steam bath for 5 min. Transfer to 250 mL vol. flask with alcohol, cool, dil. to vol. with alcohol, mix, and filter thru folded paper. Pipet 200 mL clear filtrate into centrf. bottle.

## 16.025

## Reagents

(a) *Potassium permanganate soln.*—Dissolve 5 g  $\text{KMnO}_4$  in  $\text{H}_2\text{O}$  and dil. to 100 mL.

(b) *Ferrous sulfate soln.*—Dissolve 200 g  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , dil. to 500 mL with  $\text{H}_2\text{O}$ , and add 5 mL  $\text{H}_2\text{SO}_4$ .

(c) *Lead acetate soln.*—Dissolve 75 g  $\text{Pb}(\text{OAc})_2 \cdot 3\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 1 mL  $\text{HOAc}$ , and dil. to 250 mL.

## 16.026

## Determination

To soln in centr. bottle add 10 mL  $\text{Pb}(\text{OAc})_2$  soln, shake vigorously ca 2 min, and centr. 15 min at ca 1000 rpm. Carefully decant supernate from pptd Pb salts and test with little  $\text{Pb}(\text{OAc})_2$  soln. If ppt forms, return to centr. bottle, add more Pb soln, shake, and again centr. If sediment lifts, centr. again, increasing speed and time, and decant. Invert bottle and drain thoroly several min. To Pb salts in centr. bottle add ca 150 mL  $\text{H}_2\text{O}$ , shake thoroly, and sat. with  $\text{H}_2\text{S}$ . (Caution: See 51.059.) Transfer to 250 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , mix, and filter thru folded paper.

Evap. 200 mL filtrate to ca 20 mL, rinse into 250–300 mL tared, g-s erlenmeyer, and adjust with  $\text{H}_2\text{O}$  to net wt of ca 40 g. Add 2 g  $\text{KBr}$  and 5 mL  $\text{H}_2\text{SO}_4$ , and, if necessary, heat to ca  $50^\circ$  and let stand 5 min. Slowly (1–2 mL portions) add 20 mL  $\text{KMnO}_4$  soln from pipet or buret, swirling flask few sec after each addn. Let stand undisturbed 5 min and cool to  $15^\circ$ . Slowly add  $\text{FeSO}_4$  soln with const agitation until mixt. starts to clear. Shake 1 min, continue addn of  $\text{FeSO}_4$  soln until  $\text{MnO}_2$  is dissolved, and add few mL excess. Add 20 g anhyd.  $\text{Na}_2\text{SO}_4$ , with swirling to assure soln (if  $\text{Na}_2\text{SO}_4$  remains substantially undissolved, repeat detn). Cool to  $15^\circ$  and shake vigorously 5 min.

Immediately, while still cold, collect pentabromacetone ppt on asbestos in gooch and wash residual ppt from flask with portion of filtrate. Wash crucible with 50 mL cold  $\text{H}_2\text{O}$  and leave under suction few min. Dry crucible overnight in  $\text{H}_2\text{SO}_4$  desiccator and weigh, or place crucible in drying train and aerate until loss in wt does not exceed few tenths mg, making first weighing after 20 min.

Remove pentabromacetone from crucible with alcohol followed by ether, filling crucible 3 times with each solv. Dry crucible 10 min at  $100^\circ$ , cool in desiccator, and weigh. Difference in 2 wts = wt pentabromacetone. Calc. g anhyd. citric acid from formula:  $X = 0.424P$ , where  $X$  = g citric acid in aliquot;  $P$  = g pentabromacetone; and 0.424 = theoretical factor for converting pentabromacetone to anhyd. citric acid. Anhyd. citric acid in sample taken for analysis =  $X/0.64$ .

For drying pentabromacetone by aspiration, use app. shown in Fig. 16:01, where *A* is gooch, 28 mm diam., loosely packed with cotton; *B* is gooch, 35 mm diam., for pentabromacetone; and *C* is 500 mL suction flask. Dry air by passing thru  $\text{H}_2\text{SO}_4$  and soda-lime, and finally filter thru cotton. Cool air entering drying train by passing thru spiral condenser cooled with  $\text{H}_2\text{O}$ .

Let crucible, *B*, contg pentabromacetone, remain under suction ca 1 min to remove surface moisture before placing in app. If air does not pass thru freely, place crucible in desiccator short time. Maintain slow uniform flow of air by just "cracking" suction.

## Lactic Acid (4)—Official Final Action

## 16.027

## Reagents

(a) *Barium lactate std soln.*—(Caution: See 51.011, 51.039, and 51.054.) Dissolve in ca 10 mL  $\text{H}_2\text{O}$  amt of a pure lactate, such as Li, Zn, or Ca lactate, contg equiv. of ca 300 mg free lactic acid. Transfer material to extractor, Fig. 16:02, add 0.5 mL  $\text{H}_2\text{SO}_4$  (1+1), and adjust vol. to 50 mL. Ext with ether 3 hr. Add

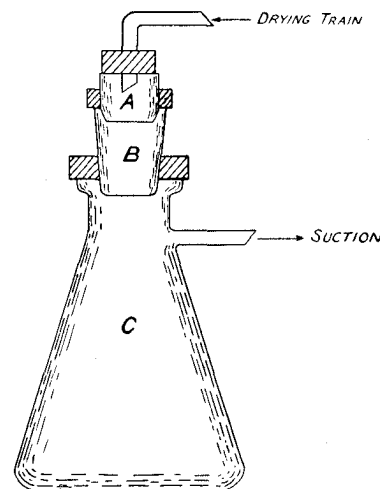

FIG. 16:01—Apparatus for drying pentabromacetone by aspiration

ca 20 mL  $\text{H}_2\text{O}$  to extn flask, evap. ether on steam bath, and carefully titr. with 0.1N  $\text{Ba}(\text{OH})_2$ , using phthln. Transfer neutzd material to 200 mL vol. flask, dil. to vol., and mix. Pipet into 500 mL vol. flask amt of this Ba lactate soln contg equiv. of exactly 250 mg free lactic acid, dil. to vol., mix, and designate as *lactate std soln.* (2 mL equiv. to 1 mg lactic acid. To plot std curve, use freshly prepd soln.) Transfer 20 mL lactate std soln to 100 mL vol. flask, dil. to vol., and designate as *dil. lactate std soln* (10 mL equiv. to 1 mg lactic acid).

(b) *Carbon.*—To 10 g high-grade C (Nuchar C-190-N, Suchar, or Darco G60) in 600 mL beaker, add ca 200 mL  $\text{H}_2\text{O}$  and 30 mL 1N  $\text{HCl}$ , and keep on steam bath 20 min, agitating continuously with air passed thru cotton. Filter on buchner and suck as dry as possible, tamping with flat-end rod. Transfer cake to beaker, add ca 200 mL  $\text{H}_2\text{O}$ , mix thoroly, and refilter. Repeat washing and filtering twice, and dry at  $100^\circ$ .

(c) *Ferric chloride soln.*—Dissolve 2 g  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 5 mL 1N  $\text{HCl}$ , and dil. to 200 mL.

## 16.028

## Preparation of Solution

(a) *Liquid, whole and skim milks.*—Weigh 50 g into 100 mL vol. flask.

(b) *Dried, whole and skim milks.*—Weigh 5 g into 100 mL beaker, and using heavy stirring rod, make into smooth paste with  $\text{H}_2\text{O}$ . Transfer mixt. to 100 mL vol. flask with ca 50 mL  $\text{H}_2\text{O}$ .

(c) *Cream and ice cream.*—Weigh 20 g into 100 mL vol. flask and add ca 50 mL  $\text{H}_2\text{O}$ .

(d) *Sweetened condensed milk.*—Weigh 25 g into 100 mL beaker and transfer to 100 mL vol. flask with ca 50 mL  $\text{H}_2\text{O}$ .

(e) *Evaporated milk.*—Weigh 25 g into 100 mL vol. flask and add ca 50 mL  $\text{H}_2\text{O}$ .

To mixts add 6 mL 1N  $\text{H}_2\text{SO}_4$  and mix, avoiding vigorous agitation. Add 5 mL 20% *phosphotungstic acid soln* (1 mL for cream and 2 mL for ice cream) and dil. to vol. with  $\text{H}_2\text{O}$ . Mix, and filter thru folded paper.

(f) *Butter.*—Weigh 20 g into centr. bottle, add 25 mL  $\text{H}_2\text{O}$ , and warm on steam bath. Neutze with 1N  $\text{NaOH}$ , using phthln. Cool, add 50 mL ether, and mix well, avoiding vigorous agitation. Add 50 mL pet ether, mix well, and centr. Draw off ether layer as completely as possible by siphon with lower end bent upward. Repeat extn, using 25 mL of each ether. Place bottle on steam bath to remove most of remaining ethers. Transfer residue in bottle to 100 mL vol. flask, add 3 mL 1N  $\text{H}_2\text{SO}_4$ , and mix. Cool mixt., and ppt proteins with 20% *phosphotungstic acid soln*,

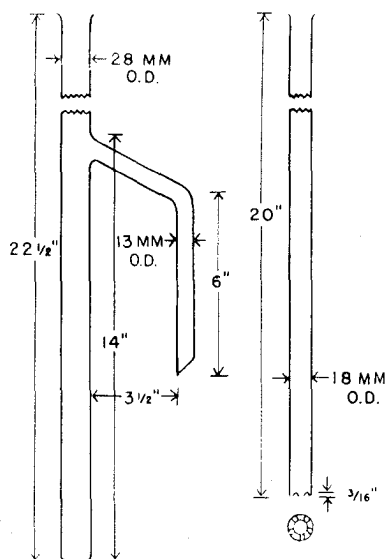

FIG. 16:02—Liquid extractor

adding reagent dropwise until pptn stops. Dil. to vol., mix by shaking, and filter thru folded paper.

**16.029****Preparation of Standard Curve**

Transfer from buret to vol. flasks, graduated at 50 and 55 mL, vols of std solns in left-hand column of Table 16:01. Right-hand column gives mg of lactic acid in 40 mL filtrate from each sample after C treatment described below, and that will therefore be read in spectrophtr. Blank using 40 mL H<sub>2</sub>O in place of lactate soln must be included in each series.

To each flask, including blank, add 6.6 mL 0.1N HCl and H<sub>2</sub>O until vol. is ca 40 mL. Now add 200±1 mg prepd C, shake, and keep on steam bath 10 min, mixing frequently. Cool, dil. to 55 mL mark with H<sub>2</sub>O at room temp., and promptly filter thru quant. paper, pouring back until clear.

Transfer 40 mL of each clear filtrate to 50 mL vol. flask, painted black or wrapped in black paper. As 40 mL filtrate used contains only 4.8 mL acid added during C treatment, add 1.2 mL 0.1N HCl. (Total of 6 mL 0.1N HCl is required in flask.) Pipet 5 mL FeCl<sub>3</sub> soln into one flask at time, dil. to vol., and mix. Pour soln into 1 cm quartz cell and det. wavelength of max. *A* on recording spectrophtr between 350 and 600 nm, using baseline correction at 600 nm. If recording spectrophtr is not available, manually

scan region around 365 nm to det. wavelength of max. *A*. Read all std solns at this wavelength against blank set at 0 *A*. (On exposure to direct light, color fades, but protected as provided it is stable for number of hr.) From readings obtained, prep. std curve, plotting mg lactic acid as abscissa and scale readings as ordinates. (Large-scale graph paper is recommended to permit more accurate interpolations.)

Recheck wavelength of max. *A* and std curve occasionally and whenever new batch of C or FeCl<sub>3</sub> is used. If different, adjust spectrophtr or prep. new std curve at new wavelength of max. *A*.

**16.030****Extraction**

(Caution: See 51.011, 51.039, and 51.054.)

Place 50 mL prepd filtrate and 0.5 mL H<sub>2</sub>SO<sub>4</sub> (1+1) in inner tube of extractor and connect to longest bulb-type condenser available, having outlet ≥13 mm id to minimize ether regurgitation. Run H<sub>2</sub>O thru condenser at max. condensation efficiency. Connect extn flask contg 200 mL ether, and lower flask slowly onto preheated heating mantle or hot plate to prevent superheating the ether. Protect extractor from heat of hot plate by upright sheet of asbestos and ext all the lactic acid.

When ether in extn flask is kept at rapid boiling and condenser H<sub>2</sub>O is cold enough to let condensed ether return to extn flask in steady stream, extn for 3 hr delivers all the lactic acid. When this rate of extn cannot be maintained because of high temp. of H<sub>2</sub>O passing thru condenser, continue extn until equiv. of 7500 mL ether has passed thru soln. Time required, *T*, established for each set of new conditions, is calcd from 2 factors: *x*, vol. ether necessary to fill extractor to overflowing at side-arm, which is constant for each app.; and *y*, time in min required for vol. *x* to pass from extn flask and fill extractor.

To det. *x*, place 50 mL H<sub>2</sub>O and 0.5 mL H<sub>2</sub>SO<sub>4</sub> (1+1) in extractor. With extractor held upright, carefully pour ether from graduate into inner tube until it just starts passing out of side-arm. Det. *y* in ordinary course of starting each detn. With stopwatch, record interval from time ether first drops from condenser and falls into inner tube to time first drops return to extn flask from overflow into side-arm. Time, *T*, necessary for 7500 mL to pass thru app. = 7500 *y*/*x*. Calcd *T*. holds only if rate of boiling and condensing is const thruout extn period.

**16.031****Determination**

To flask contg ether ext add 20 mL H<sub>2</sub>O and expel ether on steam bath. Do not let flask remain on steam bath after ether is expelled. Neutze with *satd Ba(OH)<sub>2</sub> soln*, using phthln. Wash into 110 mL vol. flask with alcohol until vol. is ca 90 mL. Heat almost to boiling on steam bath, cool, dil. to vol. with alcohol, and filter thru quant. paper. To expel alcohol, evap. 100 mL filtrate to ca 10 mL, add ca 50 mL H<sub>2</sub>O, and again evap. to ca 10 mL (or evap. the 100 mL filtrate to dryness on steam bath).

Add, from buret, 6.6 mL 0.1N HCl and transfer contents of beaker with H<sub>2</sub>O to 50–55 mL vol. flask until vol. is ca 40 mL. Prep. blank contg 6.6 mL 0.1N HCl dild to ca 40 mL with H<sub>2</sub>O. Add 200 mg prepd C, mix immediately, and keep on steam bath 10 min, mixing frequently. Cool, dil. to 55 mL mark with H<sub>2</sub>O at room temp., and filter thru quant. paper, pouring back until clear.

Transfer 10 mL filtrate to 50 mL *black vol. flask*. (Total of 6 mL 0.1N HCl must be in flask; 10 mL filtrate contains 1.2 mL 0.1N HCl from C treatment; therefore, add 4.8 mL addnl acid.) Add 5 mL FeCl<sub>3</sub> soln from buret or pipet, dil. to vol., and mix. (After color develops, dilg to reduce color intensity is not permissible.) Fill 1 cm quartz cell with soln and read in spectrophtr at wavelength of max. *A* against blank set at 0 *A*.

Table 16:01 Preparation of Dilutions for Standard Curve

Soln to be Transferred to 50–55 mL Vol. Flask, mL	Lactic Acid in 40 mL Aliquot, mg
dil. lactate std soln	
6.90	0.5
13.80	1.0
27.60	2.0
lactate std soln	
8.25	3.0
11.00	4.0
13.75	5.0
16.50	6.0
19.25	7.0
22.00	8.0
24.75	9.0
27.50	10.0
30.25	11.0
33.00	12.0

Det. amt lactic acid present in the 10 mL aliquot from std curve. If amt lactic acid in 10 mL portion is <2 mg, repeat detn on 40 mL portion of remaining filtrate. The 40 mL aliquot contains 4.8 mL 0.1N HCl; therefore, add 1.2 mL acid. Report lactic acid in mg/100 g.

$$\begin{aligned} \text{mg Lactic acid in ether ext} &= Z \\ &= \text{mg read} \times (55/10 \text{ (or } 40)) \times (110/100). \\ \text{mg Lactic acid/100 g} &= Z \\ &\times (\text{mL sample diln/mL aliquot for extn}) \times (100/\text{g sample}). \end{aligned}$$

#### Total Solids

##### 16.032 Method I—Official Final Action

Weigh 2.5–3 g prepd sample, **16.020**, into weighed flat-bottom dish  $\geq 5$  cm diam.; use ca 5 g and Pt dish if ash is to be detd on same portion. Heat on steam bath 10–15 min, exposing max. surface of dish bottom to live steam; then heat 3 hr in air oven at 98–100°. Cool in desiccator, weigh quickly, and report % residue as total solids.

##### 16.033 Method II—(Approximate) Procedure

Det. sp gr of milk with Quévenne lactometer (reading top of meniscus), observe temp., and correct reading  $L$  to 60°F by **52.023**. Calc. total solids either from formula  $0.25 L + 1.2 F$ , in which  $F$  = % fat in milk, or from **52.022**.

##### 16.034 Infrared Method—Official First Action

See **16.087**.

##### 16.035 Ash (5)—Official Final Action

Into suitable Pt dish weigh ca 5 g prepd sample, **16.020**, and evap. to dryness on steam bath. Ignite in furnace at  $\leq 550^\circ$  until ash is C-free. Cool in desiccator, weigh, and calc. % ash.

##### 16.036 Total Nitrogen—Official Final Action

Transfer 5 g sample to Kjeldahl digestion flask and proceed as in **2.057**. % N  $\times 6.38$  = % "protein."

#### Dye Binding Method I (6)—Official Final Action

##### 16.037

##### Reagents

(a) *Purified Acid Orange 12*.—Dissolve 100 g dye in 400 mL boiling  $H_2O$  and stir in 400 mL boiling denatured alcohol. Let cool at 0–5° ca 15 hr. Filter thru buchner, wash once with cold alcohol, and continue suction until alcohol is removed. Dry at 125°. Repeat recrystn and dry in vac. oven at 100°.

(b) *Reagent dye soln.*—(1) *Formulation I*.—Dissolve 1.300 g (corrected for assay) twice recrystd Acid Orange 12 in 1 L 0.05M phosphate buffer, (d). (2) *Formulation II\**.—Dissolve 1.250 g (corrected for assay) twice recrystd Acid Orange 12 in 1 L soln contg 60 mL HOAc and 10 g oxalic acid.

Make assay correction by calcg dye concn,  $c$ , in soln from  $A$ , using equation  $c = A/(5.90 \times b)$ , where  $b$  is mm path length of cell. Check soln further against either milk of known protein content or previous valid dye soln. (Same dye formulation must be used for assay and calibration.)

(c) *Reference dye soln.*—Dissolve 0.600 g twice recrystd Acid Orange 12 and 1 mL propionic acid in ca 900 mL  $H_2O$ . Dil. to 1 L with  $H_2O$ . Correct for assay as in (b) above.

(Recrystd dye and solns available from U D Corporation, 1898 Flatiron Ct, Boulder, CO 80301.)

\* Official First Action as an alternative for, but not interchangeable with, Formulation I.

(d) *0.05 M phosphate buffer*.—pH 1.8–1.9. Dissolve 3.4 g  $KH_2PO_4$ , 3.4 mL  $H_3PO_4$  (1 (85%) + 1), 60 mL HOAc, 1 mL propionic acid, and 2 g oxalic acid in ca 800 mL  $H_2O$ . Dil. to 1 L with  $H_2O$ .

##### 16.038

##### Apparatus

(a) *Spectrophotometer*.—Photoelec. colorimeter or spectrophtr set at 480 nm. Use buffer dilns of reagent dye soln representing 0.350, 0.600, 0.750, and 0.850 g/L to calibrate spectrophtr. Plot  $A$  against concn to use as calibration chart.

(b) *Short-path cell*.—Cell with path length ca 0.3 mm; flow-thru type is convenient. Measure  $A_s$  at 370 nm of 0.0400 g/L  $K_2CrO_4$  in 0.05N KOH. Calc. path length in mm,  $b$ , from  $b = A_s/0.09914$ . Arrange drain tube, and supply tube if any, according to manufacturer's instructions to ensure proper flow and liq. levels.

Suitable colorimeter with short-path, flow-thru cell, and calibration curve are available from U D Corporation.

(c) *Automatic pipet*.—Adjust to deliver 40.44 g reagent dye soln at 20° (equiv. to 39.887 g  $H_2O$ ; 40 mL). Adjust so that 10 successive deliveries are all within  $40.44 \pm 0.02$  g by wt.

(d) *Syringe*.—Stdze sampling syringe to deliver 2.24 mL at 20° (equiv. to 2.2337 g  $H_2O$ ).

(e) *Polyethylene plastic bag*.—6 oz, Whirlpak (available from Fisher Scientific Co.), or equiv.

##### 16.039

##### Preparation of Samples

(a) *Fluid milk, ice cream mix*.—Use as received.

(b) *Buttermilk, half-and-half, chocolate drink*.—Warm to 35–38° and agitate thoroly.

(c) *Nonfat dry milk (NFDM)*.—Use as powder or reconstitute as follows: Weigh plastic bag to nearest 0.5 mg. Add 1 level tablespoon NFDM (ca 7.5 g) and reweigh. Add ca 75 mL (ca 60°)  $H_2O$ . Seal bag and shake vigorously 3 min. Let cool to room temp. Do not use  $H_2O$  bath. Reweigh. Refrigerate overnight. Reconstitute new portion of NFDM sample for each replicate.

##### 16.040

##### Determination

Zero spectrophtr. Adjust gain so that ref. dye soln, (c), reads 42%T at 480 nm. Place 2.24 mL milk, buttermilk, or half-and-half, 2.5–2.8 mL chocolate drink or reconstituted NFDM, from syringe, or 2.0–2.3 g ice cream mix or 0.22–0.24 g NFDM powder in 2 oz squeeze-type polyethylene dispenser bottle with fitted spun glass paper inside cap. Det. sample wt to 0.5 mg. Add 40.44 g reagent dye soln, (b), to bottle by automatic pipet. Shake vigorously 30 sec, except shake bottle contg NFDM powder 3 min. Reset ref. dye soln reading at 42%T, if necessary. Drop filtrate from dispenser bottle into cell funnel and draw into cell. When reading is const, record to nearest 0.1%, avoiding parallax. Check spectrophtr gain. If reading is not 42% with ref. dye soln, adjust instrument, and reread sample.

All solns must be  $25 \pm 1^\circ$  when placed in cell. Measure temp. before reading; soln warms while in instrument.

##### 16.041

##### Calculations

(a) *For formulation I*.—Using calibration chart prepd for instrument, det. dye concn (mg/mL) in sample filtrate from observed reading. Vol. =  $(1/1.012) \times (\text{g sample} + 40.44)$ ; mg dye not bound = vol.  $\times$  dye concn; mg bound dye = 52 mg dye available – mg dye not bound. Protein in mg = mg bound dye/0.312.

$$\% \text{ Protein} = \text{mg protein}/(\text{g sample} \times 10).$$

% Protein in NFDM = % protein in reconstituted NFDM  $\times$  g reconstituted NFDM prepd/g NFDM sample used.

(b) *For formulation II.*—Using calibration chart prep'd for instrument, det. dye concn (mg/mL) in sample filtrate from observed reading.

$$\% \text{ Protein} = (1.250 - \text{sample dye concn})/0.1824.$$

#### *Dye Binding Method II (7)—Official First Action*

##### **16.042 Reagents and Apparatus**

(a) *Reagent dye solns.*—(1) *Working soln.*—Dissolve 9.0–9.5 g Amido Black 10B (available from Merck and Co., Inc.) in ca 3 L H<sub>2</sub>O by heating to ca 70°. Sep. dissolve 158.40 g citric acid·H<sub>2</sub>O, 19.80 g Na<sub>2</sub>HPO<sub>4</sub>·2H<sub>2</sub>O, and 3 g thymol in ca 2 L H<sub>2</sub>O. Add resulting buffer soln to dye soln. Add exactly 10 kg H<sub>2</sub>O. Let dye soln stand overnight before use. (2) *Reference std soln.*—Dil. 1 part working soln with 2.5 parts (w/w) H<sub>2</sub>O.

(b) *Spectrophotometer.*—Photoelec. colorimeter or spectrophtr set at 620 nm with 0–100 scale and nonlinear protein scale from 2.5 to 5.5% (such as ProMilk Mark II app. or automatic Pro-Milk PMA manufactured by Foss Electric Co., Hillerod, Denmark); protein extremes correspond to ca 18 and 84, resp., on 0–100 scale.

(c) *Short path cell.*—Flow-thru, with ca 0.2 mm path length.

(d) *Automatic pipet.*—Adjustable to deliver ca 20 g reagent working soln at 20°. Adjust to maintain agreement of results with Kjeldahl method, **16.036**.

(e) *Syringe.*—Adjust to deliver 1.00 g H<sub>2</sub>O at 20°.

(f) *Pneumatic pressure filter.*—App. for using slight air pressure to force sample-reagent mixt. thru Fiberglass filter and filtrate into cell.

(Suitable equipment ((a)–(f)) is available from Foss America, Inc., Rt 82, Fishkill, NY 12524.)

##### **16.043**

##### **Start-Up**

Zero spectrophtr using 0–100 scale. Dispense reagent working soln thru filter into cell according to manufacturer's directions. If reading is not 0±0.25 scale division, adjust zero control. Dispense std ref. soln thru filter into cell according to manufacturer's instructions. Adjust gain control to obtain reading of 45 on 0–100 scale. Repeat every 50 samples.

(If either gain or zero control is adjusted, repeat above steps until both readings are correct without further adjustment. This constitutes double-scale expansion.)

##### **16.044**

##### **Determination**

Install clean filter in mixing tube on filtration app. Place 1 mL prep'd sample, **16.039**, in tube, using syringe. Dispense 20 mL ref. dye soln into mixing tube. Mix according to manufacturer's directions. Apply air pressure (e.g., from squeeze bulb) to force filtrate thru filter and into cell. Release pressure and read protein content from 2.5–5.5 scale. Remove and clean mixing tube, and renew filter according to manufacturer's directions.

##### **16.045**

##### **Calibration**

Det. protein content, **16.036**, of ca 10 milk samples of type to be analyzed contg as wide a range of protein contents as possible. Perform each detn in triplicate.

Analyze known milk samples by **16.042–16.044**. If mean difference between methods is >0.02% protein, adjust vol. of ref. dye soln delivered by dispenser. Increase dye vol. if values from **16.044** are high relative to **16.036** and decrease vol. if low. Test known milk daily as check on validity of calibration.

Complete recalibration is necessary in event of disassembly, replacement, or repair of either sample syringe or dye-dispensing syringe; adjustments or repair to any part of photometric

system, other than zero and gain adjustments referred to in **16.043**; or use of new batch of reagent or ref. dye solns.

##### **16.046 Infrared Method—Official First Action**

See **16.083–16.084**.

##### **Casein—Official Final Action**

(Make detn while milk is fresh or nearly so. If delayed >24 hr, add HCHO to milk (1:2500) and keep mixt. cool.)

##### **16.047 Method I**

Place 10 g sample in beaker with 90 mL H<sub>2</sub>O at 40–42° and immediately add 1.5 mL HOAc (1+9). Stir and let stand 3–5 min. Decant on acid-washed filter, wash by decanting 2 or 3 times with cold H<sub>2</sub>O, and transfer ppt to filter. Wash once or twice on filter. (Filtrate should be clear, or nearly so.) If first portions of filtrate are not clear, refilter, and finish washing ppt. Retain filtrate for detn of albumin, **16.050**. Det. N in washed ppt and paper as in **2.057**, and multiply result by 6.38 to obtain equiv. of casein.

To preserved sample of milk, add HOAc (1+9) dropwise with stirring, and continue addn until liq. above ppt becomes clear, or very nearly so.

##### **Method II (8)**

##### **16.048**

##### **Reagent**

Pipet 250 mL 1N HOAc into 1 L vol. flask. Add 125 mL CO<sub>2</sub>-free 1N NaOH, dil. to vol. with CO<sub>2</sub>-free H<sub>2</sub>O, and mix thoroly.

##### **16.049**

##### **Determination**

Pipet 20 mL sample into 100 mL vol. flask. Add 50 mL reagent, mix, dil. to vol. with H<sub>2</sub>O, and shake well. Set flask in 50–60° H<sub>2</sub>O (not >60°) for 15 min. Cool to room temp., add 0.5 g Celite analytical filter-aid, shake thoroly, and filter clear thru suitable folded paper, avoiding evapn during filtration. Det. N, x, in 50 mL clear filtrate, and det. total N, y, in 10 mL of the milk. (y – x) × 6.38 = casein in 10 mL milk. Report g casein/100 mL milk, or divide g/100 mL by density of milk and report as % by wt.

##### **16.050 Albumin—Official Final Action**

Exactly neutze filtrate obtained in **16.047** with 10% NaOH soln, add 0.3 mL HOAc (1+9), and heat on steam bath until albumin is completely pptd. Collect ppt on acid-washed filter, wash with cold H<sub>2</sub>O, and det. N as in **2.057**. N × 6.38 = albumin.

##### **Protein-Reducing Substances (9)—Official Final Action**

(Complete analyses same day they are begun. Do not permit tests to stand too long after cooling or after filtration. Oxidizing or reducing fumes (H<sub>2</sub>S, Cl, HNO<sub>3</sub>, etc.) must be absent from laboratory during detn.)

##### **16.051**

##### **Reagents**

(a) *Phthalate buffer soln.*—pH 5.6. Dissolve 2.0 g NaOH in H<sub>2</sub>O and dil. to 250 mL. Dissolve 10.2 g KH phthalate in H<sub>2</sub>O and dil. to 250 mL. Mix 159 mL NaOH soln with 200 mL phthalate soln and dil. to 800 mL in graduate. Adjust to pH 5.6 by addn of NaOH or phthalate soln.

(b) *Potassium ferricyanide soln.*—1%. Dissolve 10 g K<sub>3</sub>Fe(CN)<sub>6</sub> in H<sub>2</sub>O and dil. to 1 L. Discard if soln appears green or contains blue ppt. Prep. new std curve with each new batch of reagent.

(c) *Ferric chloride soln.*—0.1%. Dissolve 0.1 g or 0.1 mL liquefied portion of FeCl<sub>3</sub>·6H<sub>2</sub>O in 100 mL H<sub>2</sub>O. Prep. fresh daily.

**16.052****Apparatus**

(a) *Centrifuge tubes*.—50 mL graduated, Pyrex, conical red line, Corning No. 8100.

(b) *Spectrophotometer*.—For use in visible range, with matched set of 10 mm Corex cells.

**16.053****Preparation of Standard Curve**

Weigh 0.1147 g  $K_4Fe(CN)_6 \cdot 3H_2O$  just before use and dil. to 1 L with  $H_2O$ . Dil. 50 mL to 100 mL in vol. flask (1 mL = 0.05 mg  $K_4Fe(CN)_6$ ). Pipet 0, 0.5, 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, and 4 mL of the dil. soln into series of clean, dry test tubes. Pipet in  $H_2O$  to give total vol. of 5.0 mL. To each tube add 5 mL of "blank soln" prepd as follows: Dil. 3 mL satd urea soln to 15 mL with  $H_2O$ ; add 5 mL phthalate buffer soln, 5 mL  $K_3Fe(CN)_6$  soln, (b), and 5 mL 10% trichloroacetic acid soln. Mix with stirring rod.

At convenient intervals add 1 mL of the  $FeCl_3$  soln to each tube, mix, and after exactly 10 min read in spectrophtr set to read 100%T at 610 nm with control soln (0.0 mL  $K_4Fe(CN)_6$  soln). Plot %T against mg  $K_4Fe(CN)_6$  on semilog paper.

**16.054****Determination**

Store samples preferably at ca 3°. Frozen or preserved samples are unsuitable for test.

Mix sample thoroly by pouring into container and back until homogeneous. Pipet 15 mL sample into 50 mL graduated centr. tube contg 15 mL  $H_2O$ . Add 3 mL 5% HOAc soln, stir thoroly, and centr. 5 min at 1000–1500 rpm. Decant supernate. (Small amt of floating curd may be disregarded; if sample contains excessive cream, curd will float and supernate cannot be decanted. Discard test and remix sample thoroly.) Wash ppt twice with 15 mL portions  $H_2O$ , each time mixing ppt with rod, centrfg 5 min, and decanting.

To ppt and to clean centr. tube as blank, add 3 mL satd urea soln and then dil. to 15 mL with  $H_2O$ . Stir thoroly, add 5 mL phthalate buffer soln and 5 mL 1%  $K_3Fe(CN)_6$  soln, and stir. Place in 70°  $H_2O$  bath exactly 20 min and cool in ice- $H_2O$ .

When cool, add 5 mL 10% trichloroacetic acid soln, stir, and filter thru 11 cm Whatman No. 40 paper, or equiv. Use first few mL filtrate to wash sides and bottom of receiver, and discard. Filter remainder of soln and let drain completely; then refilter if cloudy.

Add 5 mL  $H_2O$  to clean, dry test tube and add 5 mL clear filtrate. Add 1 mL 0.1%  $FeCl_3$  soln to develop color. Stir, and let stand exactly 10 min. Read in spectrophtr set to read 100%T at 610 nm against blank. With series of samples, add  $FeCl_3$  soln at convenient intervals to permit readings 10 min after addn. From std curve, det. amt of reducing substances as mg  $K_4Fe(CN)_6$  and calc. to 100 mL milk basis by multiplying by 40 (100/2.5 mL equiv. aliquot).

**Lactose****Polarimetric Method (10)—Official Final Action****16.055****Reagents**

(a) *Acid-mercuric nitrate soln*.—Dissolve Hg in twice its wt  $HNO_3$  and dil. with 5 vols  $H_2O$ . Or—

(b) *Mercuric iodide soln*.—Dissolve 33.2 g KI and 13.5 g  $HgCl_2$  in 200 mL HOAc and 640 mL  $H_2O$ .

**16.056****Determination**

Weigh 65.8 g (2 normal wt) milk into each of 2 vol. flasks, 100 and 200 mL, resp. To each flask add 20 mL acid- $Hg(NO_3)_2$  soln or 30 mL  $HgI_2$  soln. To 100 mL flask add 5% phosphotungstic acid soln to mark, and to the 200 mL flask add 15 mL 5%

phosphotungstic acid soln and dil. to mark with  $H_2O$ . Shake both flasks frequently during 15 min, filter thru dry filter, and polarize. (It is preferable to read soln from 200 mL flask in 400 mm tube to reduce error of reading; soln from 100 mL flask may be read in 200 mm tube.) Calc. % lactose in sample as follows: (1) Subtract reading of soln from 200 mL flask (using 400 mm tube) from reading of soln from 100 mL flask (using 200 mm tube); (2) multiply difference by 2; (3) subtract result from reading of soln from 100 mL flask; (4) divide result by 2.

**16.057 Gravimetric Method—Official Final Action**

Dil. 25 g sample with 400 mL  $H_2O$  in 500 mL vol. flask. Add 10 mL  $CuSO_4$  soln, 31.034(a), and ca 7.5 mL KOH soln of such concn that 1 vol. is just enough to completely ppt the Cu as hydroxide from 1 vol. of the  $CuSO_4$  soln. (Instead, 8.8 mL 0.5N NaOH may be used. After addn of alkali soln, mixt. must still be acid and contain Cu in soln.) Dil. to vol., mix, filter thru dry filter, and det. lactose in aliquot of filtrate as in 31.038. From 52.019 obtain wt lactose equiv. to wt  $Cu_2O$ .

**16.058 Infrared Method—Official First Action**

See 16.085–16.086.

**Fat****16.059 Roese-Gottlieb Method (Reference Method) (11)—Official Final Action**

(Details of this method comply with method which has been agreed upon by International Dairy Federation, International Organization for Standardization, and AOAC for publication by each organization and which is published as international std in *FAO/WHO Code of Principles Concerning Milk and Milk Products and Associated Standards*.)

(Caution: See 51.011, 51.039, 51.054, and 51.073.)

Prep. as in 16.020 and weigh, to nearest mg, ca 10 g sample into fat-extn flask or tube. Add 1.25 mL  $NH_4OH$  (2 mL if sample is sour) and mix thoroly. Add 10 mL alcohol and mix well. Add 25 mL ether (all ether must be peroxide-free), stopper with cork or stopper (synthetic rubber) unaffected by usual fat solvs, and shake very vigorously 1 min. Cool, if necessary; add 25 mL pet ether (boiling range 30–60°) and repeat vigorous shaking. Centr. flask at ca 600 rpm or let it stand until upper liq. is practically clear. Decant ether soln into suitable flask or metal dish. Wash lip and stopper of extn flask or tube with mixt. of equal parts of the 2 ethers and add washings to weighing flask or dish. Repeat extn of liq. remaining in flask or tube twice, using 15 mL of each solv. each time and adding  $H_2O$  if necessary, but omitting rinsing with mixed solvs after final extn. (Third extn is not necessary with skim milk.)

Evap. solvs completely on steam bath at temp. that does not cause spattering or bumping (boiling chips may be added). Dry fat to const wt in oven at  $102 \pm 2^\circ$  or vac. oven at 70–75° under pressure <50 mm Hg (6.7 kPa). Weigh cooled flask or dish, without wiping immediately before weighing. Remove fat completely from container with 15–25 mL warm pet ether, dry, and weigh as before. Loss in wt = wt fat. Correct wt fat by blank detn on reagents used. If blank is >0.5 mg, purify or replace reagents. Difference between duplicate detns obtained simultaneously by same analyst should be  $\leq 0.03$  g fat/100 g product.

**Babcock Method (12)—Official Final Action****16.060****Apparatus**

(a) *Standard Babcock milk-test bottle*.—8%, 18 g, 6" milk-test bottle, total ht 150–165 mm (5.9–6.5"). Bottom of bottle is flat,

and axis of neck is vertical when bottle stands on level surface. Quantity of milk for bottle is 18 g.

(1) *Bulb*.—Capacity of bulb to junction with neck must be  $\geq 45$  mL. Shape of bulb may be either cylindrical or conical. If cylindrical, od must be between 34 and 36 mm; if conical, od of base must be between 31 and 33 mm, and max. diam. between 35 and 37 mm.

(2) *Neck*.—Cylindrical and of uniform diam. from  $\geq 5$  mm below lowest graduation mark to  $\geq 5$  mm above highest mark. Top of neck is flared to diam. of  $\geq 10$  mm. Graduated portion of neck has length  $\geq 63.5$  mm and is graduated in whole %, 0.5%, and 0.1%, resp., from 0.0 to 8.0%. Tenths % graduations are  $\geq 3$  mm long; 0.5% graduations are  $\geq 4$  mm long and project 1 mm to left; and whole % graduations extend at least half-way around neck to right and project  $\geq 2$  mm to left of tenths % graduations. Each whole % graduation is numbered, with number placed to left of scale. Capacity of neck for each whole % on scale is 0.20 mL. Max. error of total graduation or any part thereof must not exceed vol. of smallest unit of graduation.

Each bottle must be constructed so as to withstand stress to which it will be subjected in centrf.

(3) *Testing*.—Hg and cork, alcohol and buret, and alcohol and brass plunger methods may be used for rapid testing of bottles, but accuracy of any questionable bottle must be detd by calibration with Hg (13.5471 g clean, dry Hg at 20° to be equal to 5% on scale of 18 g bottle and 10% on scale of 9 g bottle, 16.157(a)), bottle having been previously filled to 0 with Hg.

(b) *Pipet*.—Std milk pipet conforms to following specifications:

	mm
Total length .....	$\leq 330$
Od of suction tube .....	6–8
Length of suction tube .....	130
Od of delivery tube (Must fit into bottle (a)) .....	4.5–5.0
Length of delivery tube .....	100–120
Distance of graduation mark above bulb .....	15–45
Nozzle parallel with axis of pipet, but slightly constricted so as to discharge in 5–8 sec when filled with H <sub>2</sub> O.	
Graduation, to contain 17.6 mL H <sub>2</sub> O at 20° when bottom of meniscus coincides with mark on suction tube.	
Max. error in graduation, $\leq 0.05$ mL. Pipet is to be marked "Holds 17.6 mL."	

Test pipet by measuring from buret vol. H<sub>2</sub>O (at 20°) which it holds up to graduation mark.

(c) *Acid measure*.—Device used to measure H<sub>2</sub>SO<sub>4</sub>, whether graduate or pipet attached to Swedish acid bottle, must be graduated to deliver 17.5 mL.

(d) *Centrifuge or "tester"*.—Std centrf., however driven, must be constructed thruout and so mounted as to be capable, when filled to capacity, of rotating at necessary speed with min. vibration and without liability of causing injury or accident. It must be heated, elec. or otherwise, to temp. of  $\geq 55^\circ$  during centrfg. It must be provided with speed indicator, permanently attached, if possible. Proper rate of rotation may be detd by ref. to table below. By "diam. of wheel" is meant distance between inside bottoms of opposite cups measured thru center of rotation of centrf. wheel while cups are horizontally extended.

Diam of wheel, inches	rpm
14	909
16	848
18	800
20	759
22	724
24	693

(e) *Dividers or calipers*.—For measuring fat column.

(f) *Water bath for test bottles*.—Provided with thermometer and device to maintain temp. of 55–60°.

(g) *Reading light*.—As background when measuring fat columns. Light should be diffused (soft green color preferred) and provide illumination from angles above and below level of fat column. Attached magnification devices are suggested.

## 16.061

## Determination

With pipet, (b), transfer 18 g prepd sample, 16.020, to milk-test bottle. Blow out milk in pipet tip ca 30 sec after free outflow ceases. Adjust milk to ca 22° and add portionwise ca 17.5 mL H<sub>2</sub>SO<sub>4</sub> (sp gr 1.82–1.83 at 20°) tempered at  $22 \pm 1^\circ$ , washing all traces of milk into bulb. Immediately shake by rotation until all traces of curd disappear (reaction temp. should be 100–105°); place bottle in heated (ca 60°) centrf., counterbalance, and after proper speed is reached, centrf. 5 min. Add soft H<sub>2</sub>O at 60°, or above, until bulb of bottle is filled. Centrf. 2 min. Add hot H<sub>2</sub>O until liq. column approaches top graduation of scale. Centrf. 1 min longer at ca 60°. Transfer bottle to warm H<sub>2</sub>O bath kept at 55–60° (preferably 57°), immerse it to level of top of fat column, and leave until column is in equilibrium and lower fat surface assumes final form ( $\geq 5$  min). Remove bottle from bath, wipe it, and with aid of reading light, 16.060(g), use dividers or calipers to measure fat column, in terms of % by wt to nearest 0.05%, from lower surface to highest point of upper meniscus.

Fat column, at time of measurement, should be translucent, golden-yellow or amber, and free from visible suspended particles. Reject all tests in which fat column is milky or shows presence of curd or of charred matter, or in which reading is indistinct or uncertain; repeat test, adjusting vol. H<sub>2</sub>SO<sub>4</sub> added.

## 16.062 ★ Rapid Detergent Method for ★ Raw Milk (13)—Official Final Action

See 16.055–16.057, 11th ed.

## AUTOMATED METHODS

(Following manufacturers have shown thru studies published in JAOAC that their instruments can meet indicated specifications:

*Automated Method I*: Mark III Industrial Model and Model UFM 100 with photometer and calibration units for each type of milk, manufactured by Foss Electric, Hillerod, Denmark and available from Foss America, Inc., PO Box 504, Fishkill, NY 12524; Anritsu milk-checker K373A, available from American Metering Systems, PO Box 129, Hopewell Junction, NY 12533.

*Automated Method II*: Technicon Instruments Corp.

*Infrared Methods*: "IRMA" Model Mark II, available from Accurate Metering Systems, Inc., 1731 Carmen Dr, Elk Grove Village, IL 60007; Milko-Scan Model 300 or 203, available from Foss America, Inc. and Foss Electric Canada, Ltd, 700 Campbell St, Cornwall, Ontario, Canada K6H 6C9; Multispec, available from Shields Instrument Ltd, Osbaldwick Industrial Estate, Osbaldwick, York YO1 3US, UK, and Berwind Instrument Group, Suite 378, 30100 Telegraph Rd, Birmingham, MI 48010.)

## Automated Method I (14)—Official First Action

(All models applicable to raw, unhomogenized milk; Mark III Industrial Model and Anritsu Milk-Checker are also applicable to homogenized milk)

## 16.063

## Principle

Milk is homogenized to produce uniform-size fat globules, treated with EDTA soln to dil. sample and eliminate turbidity

★ Surplus method—see inside front cover.

caused by casein micelle, and passed thru photocell to measure light scattering of soln which is proportional to amt fat in milk. Amt of light passing thru photocell is registered on galvanometer calibrated to read % fat directly.

**16.064****Apparatus and Reagents**

(a) *Instrument*.—Number of firms manufacture various model instruments based upon principle, 16.063. It is imperative that individual instrument utilized meet performance requirements of 16.066 and is applicable to type of milk to be analyzed, i.e., raw unhomogenized or homogenized.

(b) *Sodium (tetra) ethylenediamine tetraacetate (EDTA) soln.*—Dissolve 45.0 g Na<sub>2</sub>EDTA, 10.0 mL polysorbate 20 (Tween 20), and 7.6 g NaOH in 10 L H<sub>2</sub>O, using container connected to tester with plastic hose.

**16.065****Operation of Tester**

Sampling, homogenization, and heating are performed automatically, as may be mixing of EDTA. Most of mixt. purges instrument of previous sample. Mixt. flows into photometer where light at 600 nm passes thru mixt. and is automatically measured with galvanometer or digital readout in % fat when tester is calibrated by testing samples of milk by ref. method as in 16.066.

**16.066****Calibration of Tester**

(Sep. calibrations, using different calibration units and samples, are required for homogenized and unhomogenized milks.)

Test in triplicate 20 representative milks, ranging from 3 to 6% fat by 16.059 or 16.061 and tester. Calc. av. for each sample by each method to nearest 0.01%. Calc. std deviation of difference,  $S_D$ , as follows:

$$S_D = \sqrt{[\sum(D^2) - ((\sum D)^2/N)]/(N-1)}$$

where  $D$  = av. of results by 16.059 or 16.061 on sample minus av. of tester results on same sample, e.g.,

$$[(B_1 + B_2 + B_3)/3] - [(M_1 + M_2 + M_3)/3] = D;$$

where  $B$  = reading by 16.059 or 16.061 and  $M$  = reading by tester; and  $N$  = number of samples tested. If specification of 20 samples is exceeded, include all samples tested in calcs except for those for which an error in  $\geq 1$  detns can be proven.

Tester is properly calibrated when  $S_D$  so calcd is  $\leq 0.10$  for individual cow sample or  $\leq 0.06$  for herd or composite samples. Should  $S_D$  exceed these values, adjust vol. EDTA soln and/or

elect. input to galvanometer of tester in accordance with manufacturer's instructions for calibration and operation.

During any calendar day of use, make performance check consisting of comparison of results obtained on 1 milk bulk sample, using both tester and 16.059 or 16.061. If difference is  $>0.10\%$  fat, repeat detn on 3 addnl samples. If av. differences of 3 addnl samples is  $>0.10\%$  fat, recalibrate tester.

**16.067****Collection and Preparation of Samples**

See 16.019–16.020.

**16.068****Determination**

Bring sample(s) in loosely stoppered bottle to 35–40° in H<sub>2</sub>O bath. Mix by pouring gently from original container into another container. Repeat 4 times. Do *not* mix all samples at once and then let them stand before testing. *Immediately* after mixing sample, obtain readings as in 16.065.

**Automated Method II (15)—Official First Action**

(Applicable to raw, whole, mixed herd milk)

**16.069****Principle**

Raw whole milk is dild with H<sub>2</sub>O contg surfactant, mixed with HOAc contg different surfactant, serially dild with H<sub>2</sub>O contg surfactant, heated to 60°, and passed thru flowcell to measure light scattering of soln, which is proportional to amt dispersed fat in milk.  $T$  is measured at 600 nm on instrument calibrated to read % fat directly. Response is linear in range 2–6%. Presence of formalin results in slight pos. bias,  $<0.04\%$  fat; HgCl<sub>2</sub> and K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> have no effect.

**16.070****Apparatus**

*Automatic analyzer*.—See Fig. 16.03. AutoAnalyzer II with following modules (Technicon Instruments Corp.): Sampler IV with rotary mixer; proportioning pump; manifold cartridge with temp. controlled heating bath; colorimeter with flowcell and 600 nm filters; and recorder with chart paper calibrated 0–10% in 0.05%.

**16.071****Reagents**

(a) *Milk fat reagent*.—Mix 1.6 mL dialkyl quaternary ammonium chloride (Arquad 2C-75; Armak Chem. Div., PO Box 1805, Chicago, IL 60690) and ca 500 mL HOAc in 1 L vol. flask, dil. to

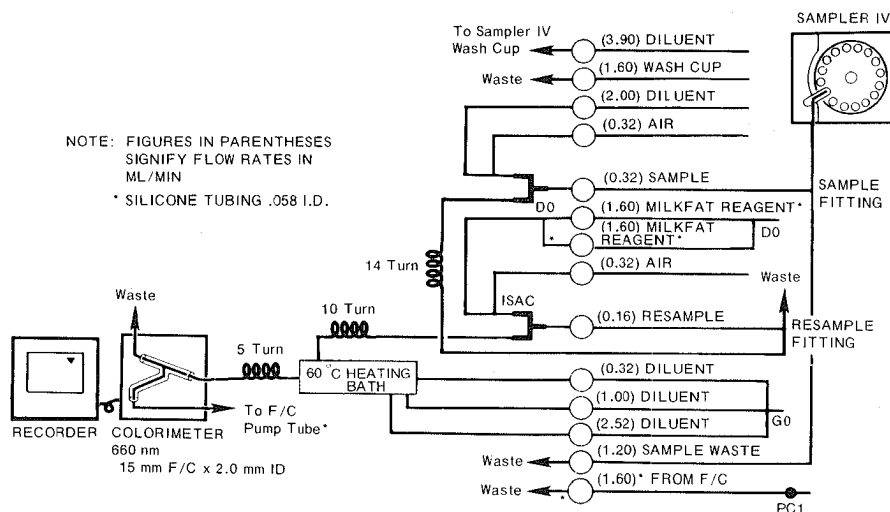

FIG. 16.03—Flow diagram for determination of fat in milk

vol. with HOAc, and mix. (Prepd reagent is available from Technicon Instruments Corp., No. Tol-5049.) Store at room temp. in glass bottles. Rate of consumption is 4.8 mL/sample. Do *not* let this reagent come in contact with Tygon tubing.

(b) *Stock diluent*.—Mix equal vols Triton X-100 (Rohm & Haas Co.) and absolute MeOH.

(c) *Milk diluent*.—Dil. 2 mL stock diluent, (b), to 1 L with H<sub>2</sub>O and mix. Prep. fresh just before use. Rate of consumption is 6.0 mL/sample.

**16.072****Preparation of Standards**

(a) *High std milk*.—Approx. 4%. Det. fat content by **16.059** or **16.061**.

(b) *Low std milk*.—1.5–2.0% fat. Dil. high std milk with skim milk. Det. fat content by **16.059** or **16.061**.

**16.073****Start-Up Procedure**

Turn on colorimeter and heating bath. (These may be left on when app. is used daily.) Place milk fat reagent line in milk fat reagent reservoir, and start proportioning pump. After 5 min, insert H<sub>2</sub>O lines into milk diluent and let reagents pump 10 addnl min. During this period, invert PC1 valve, let fill 1/3 with liq., and reposition. Check bubble pattern for uniform segmentation; check for leaks; maintain heating bath at 60±1°. Turn on chart drive and pen recorder switches. Operate app. at max. energy for sample and ref. flowcells and adjust mech. aperture, if necessary, to obtain 90–95% deflection. Proceed as in **16.075**.

**16.074****Shut-Down Procedure**

After last sample curve has appeared on recorder, turn off sampler and pump reagents thru system 10 min more. Turn recorder off. Remove H<sub>2</sub>O lines and let milk fat reagent pump 1 min more. Remove milk fat reagent line and let system pump until lines are dry. Turn off pump and remove platen.

**16.075****Calibration**

Place low std milk in first 2 positions of sampler tray and high std milk in next 2 positions. Turn on sampler. (Approx. 6 min is required for first sample to reach flowcell.) During this period, adjust elec. 0 to record same value as detd for low std milk. When first low std milk reaches recorder, use baseline control to adjust recorder to read predetd fat content. If necessary, adjust as second low milk std passes thru flowcell. When high milk std passes thru flowcell, use "std cal" control to adjust recorder to read predetd value. If necessary, adjust for second high fat sample. Proper recorder response is indicated by level peak for ca 15 sec.

**16.076****Determination**

Prep. sample as in **16.020**. Transfer 6–7 mL warm aliquot to sampler tray test tube, immediately after high milk std. About 1.8 mL is aspirated into system. Pace transfer of samples to test tubes to avoid visible formation of cream layer. For duplicate analyses, transfer freshly mixed sample to sep. sample tube. Read result from chart paper. Sampler may be operated at 60/hr if fat content varies <0.5%. Place high milk std after every 10–12 samples to check calibration. Use *baseline control*, if necessary to adjust to predetd value of high milk std.

**16.077****Operating Notes**

Drift of baseline caused by accumulation of small air bubbles in flowcell may be eliminated by momentarily pinching flow-thru line.

Erratic response may be due to accumulation of milk solids in sample line, resample line, and waste milk line just beyond roller contact. Pinching lines at point of accumulation will correct problem.

After prolonged use, fat may accumulate on sampler stirrer. Rinse stirrer with water from wash bottle.

**Infrared Milk Analysis (76)****Interim Official First Action****16.078****Principle**

Analysis of milk by IR is based on absorption of IR energy at specific wavelengths by carbonyl groups in ester linkages of fat molecules (5.723  $\mu$ m), by peptide linkages between amino acids of protein molecules (6.465  $\mu$ m), and by OH groups in lactose molecules (9.610  $\mu$ m). Total solids are detd by assigning experimentally detd factor to percentage of all other solid milk components, and by adding this amt to total % fat, protein, and lactose. Analysis by IR is dependent on calibration against suitable std method. See "Definition of Terms and Explanatory Notes" item (24), for calcn of regression lines.

**16.079****Performance Specifications**

Number of firms manufacture various model instruments based upon principle, **16.078**. It is imperative that individual instrument utilized meet following performance specifications, based upon analysis of 8 samples:

Std deviation of difference between duplicate instrument estimates:

Fat, protein, and lactose	≤0.02%	Total solids	≤0.04%
---------------------------	--------	--------------	--------

Mean difference between duplicate instrument estimates:

Fat, protein, and lactose	≤0.02%	Total solids	≤0.03%
---------------------------	--------	--------------	--------

Std deviation of difference between instrument estimates and values by ref. methods:

Fat ( <b>16.059</b> ), protein		Total solids	
( <b>16.036</b> ), and lactose		( <b>16.032</b> )	≤0.12%
( <b>16.056</b> or <b>16.057</b> )	≤0.06%		

Mean difference between instrument estimates and values by ref. methods:

Fat, protein, and lactose	≤0.05%	Total solids	≤0.09%
---------------------------	--------	--------------	--------

Calc. std deviation of difference as in **16.066**, where  $S_0$  = algebraic difference either between duplicate instrument estimates or between instrument estimates and values by ref. methods.

**16.080****Precautions**

Differences in fat readings for homogenized and unhomogenized samples of same milk should be <0.05% to assure accurate results at high fat levels. If larger differences occur and servicing homogenizer does not correct fault, consult manufacturer. Changes in moisture vapor content of instrument console will cause changes in optical 0 and shift in calibration level. Replace desiccant frequently, preferably at end of each day, as 3–4 hr are required to restore equilibrium conditions. For best accuracy, calibrate with type of milk to be analyzed (herd, individual cow, homogenized, unhomogenized, market, etc.). Do not use mixts of cream and milk for calibration. Avoid abnormal (low lactose) milks for calibration. Single pumping of milk thru instrument sample cell should purge ≥99% of previous sample. To test purging efficiency, perform fat detns on H<sub>2</sub>O and single pasteurized, homogenized whole milk in sequence: H<sub>2</sub>O, H<sub>2</sub>O, milk, milk, H<sub>2</sub>O, etc., until total of 20 detns have been obtained. Calc.

$$\text{purging efficiency} = (\Sigma M_1 - \Sigma W_2) \times 100 / (\Sigma M_2 - \Sigma W_2),$$

where  $M_1$  and  $M_2$  are first and second values for milk and  $W_2$  second value for  $H_2O$ .

### I. Fat

**16.081**

#### Calibration

Before first calibration, check linearity of output signals. Mix accurately measured vols of  $H_2O$  and homogenized cream to prep. ca 8 mixts of known relative fat contents covering required range. Prep. samples as in **16.020**, and pump each mixt. into instrument twice, using second readings to prep. plot against relative concns. If plot is not linear, adjust as indicated in operating manual. Repeat measurements and adjustments until plot is linear.

If analyzing unhomogenized milks, check linearity again with ca 4 dilns of unhomogenized cream or high fat milk. If these mixts deviate significantly from linearity, see **16.080** and check differences between readings for homogenized and unhomogenized milk samples.

Det. % fat for series of  $\geq 8$  preanalyzed (**16.059**) milk samples of type to be analyzed (see **16.080**). Prep. samples as in **16.020** and analyze in triplicate. Compare averages of second and third instrument readings with std values and follow instructions in operating manual for required changes to calibration.

**16.082**

#### Determination

Prep. sample as in **16.020**. Operate instrument in accordance with manufacturer's instructions.

### II. Protein

**16.083**

#### Calibration

Proceed as in **16.081**, first and last par., substituting Ca propionate soln (dissolve 15.0 g pure Ca propionate in  $H_2O$  and dil. to 1 L with  $H_2O$  at  $20^\circ$ ) for homogenized cream to prep. mixts of known relative concns from 0 to required max. for protein. Det. % protein for series of  $\geq 8$  preanalyzed (**16.036**) milk samples having range of protein content approx. that of population of milks to be analyzed. Prep samples as in **16.020** and analyze in triplicate. Compare averages of second and third instrument readings with std values and follow directions in operating manual for making required adjustments to calibration.

**16.084**

#### Determination

Prep. sample as in **16.020**. Operate instrument according to manufacturer's instructions.

### III. Lactose

**16.085**

#### Calibration

Proceed as in **16.081**, par. 1, substituting lactose soln (dissolve 50.00 g lactose in  $H_2O$  and 0.25 g  $HgCl_2$  in  $H_2O$  and dil. to 1 L with  $H_2O$  at  $20^\circ$ ) for homogenized cream to prep. mixts of known relative concns ranging from 0 to required max. for lactose. Det. lactose for series of  $\geq 8$  preanalyzed (**16.052** or **16.053**) milk samples having range of lactose content approx. that of population of milks to be analyzed.

Prep. samples as in **16.020** and analyze in triplicate. Use averages of second and third values for each sample in estg calibration requirements. Adjust instrument controls, as directed in operating manual, to make  $\Sigma L = \Sigma L'$ , where  $L$  = instrument readings for lactose and  $L'$  = values from ref. method.

**16.086**

#### Determination

Prep. sample as in **16.020**. Operate instrument according to manufacturer's instructions.

### IV. Total Solids

**16.087**

#### Calibration

Use std method **16.032** to det. % total solids for series of  $\geq 8$  milks. Det. % fat, % protein, and % lactose. Calc. mean difference for total solids ( $TS$ ) —  $F - P - L = a$ , where  $F$ ,  $P$ , and  $L$  are ests of fat, protein, and lactose, resp. For routine control of calibration, analyze addnl series of milks and adjust value for mean difference in accordance with accumulated data.

Calc. % total solids =  $a + F + P + L$ .

**16.088–16.096**

#### Reserved

#### Added Water

#### 16.097 Acetic Serum Method (18)—Official Final Action

(a) *Zeiss immersion refractometer reading.*—To 100 mL sample, measured at  $20^\circ$  into beaker, add 2 mL 25% HOAc (sp gr 1.035). Cover beaker with watch glass, keep in  $H_2O$  bath 20 min at  $70^\circ$ , then in ice- $H_2O$  10 min, and sep. curd from serum by rapid filtration thru small filter. Transfer portion of clear serum to refractometer beaker, place in constant temp. bath, and take refractometer reading when temp. of serum is exactly  $20^\circ$ , as detd by thermometer graduated in  $0.1^\circ$ . (Scale readings are identical on Bausch & Lomb refractometers except those with serial Nos. 4000–10,000, for which readings of 38.6 and 39.6 correspond, resp., to 39 and 40 on Zeiss instrument. (Zeiss scale =  $B \& L \text{ scale} \times 1.0092$ .)

(b) *Ash.*—Transfer 25 mL serum to weighed flat-bottom Pt dish and evap. to dryness on  $H_2O$  bath. Heat over low flame (to avoid spattering) until contents are thoroly charred, place dish in furnace, and ignite to white ash at  $\leq 500^\circ$ . Cool and weigh. Express result as g/100 mL.

#### 16.098 Copper Serum Method (19)—Official Final Action

To 1 vol.  $CuSO_4$  soln (72.5 g  $CuSO_4 \cdot 5H_2O/L$ , adjusted if necessary to read 36 at  $20^\circ$  on scale of Zeiss immersion refractometer, or to sp gr of 1.0443 at  $20/4^\circ$ ), add 4 vols milk. Shake well and filter. Det. refractometer reading of clear serum at  $20^\circ$ . (Scale readings are identical on Bausch & Lomb immersion refractometers except those with serial Nos. 4000–10,000 for which reading of 35.6 corresponds to 36 on Zeiss instrument.)

### CRYOSCOPIC METHODS

Temps used in Hortvet scale for detg fp of milk were initially thought to be equiv. to Celsius scale. Subsequently, it has been shown that fp of std salt soln at  $-0.422^\circ H$  is actually  $-0.406^\circ C$  and the one at  $-0.621^\circ H$  is  $-0.598^\circ C$ , producing  $>3.7\%$  error between the 2 scales. Most cryoscopes are calibrated in terms of  $^\circ H$  but results are reported in  $^\circ C$ . Original error, which has since led to use of this unconventional temp. scale, was made at time when methods for detg fps were not as precise as at present. Data in methods **16.099–16.108** have now been converted to  $^\circ C$  as should all similar data in future. Convert  $^\circ H$  to  $^\circ C$  by formula:

$$^\circ C = [(0.1915 \times (-^\circ H)) - 0.0004785]/0.199,$$

$$^\circ H = [(0.199 \times (-^\circ C)) + 0.0004785]/0.1915,$$

where  $^\circ H$  is absolute  $^\circ H$  reading below fp of  $H_2O$ .

**16.099 ★ Hortvet Method (20) ★**  
**Official Final Action**

See 16.086–16.088, 12th ed.

**Thermistor Method (21)—Official Final Action**

**16.100**

**Cryoscope**

Consists of cooling bath, sample agitator, seeding rod, thermistor probe (elec. resistance thermometer), and Wheatstone bridge and galvanometer, or taut band meter measuring circuit. Bath may be cooled by mech. or elec. means or by insulated ice-salt mixt. Sample may be immersed in cooling bath or bath may be "brought up" to sample mech. Observed fp value is read from measuring dial, calibrated in millidegrees C (0.001°C; more correctly, degrees Hortvet or "H"), when galvanometer or meter is nulled by rotation of dial.

Fill cooling bath at room temp. to proper level each time instrument is used. Proper coolant level is detd by observing coolant issuing from bath overflow or by visually checking coolant level, depending on the make and model of cryoscope. Cooling bath temp. should be  $-7$  or  $-8 \pm 0.5^\circ$ , depending on make of cryoscope, and temp. is measured by placing thermometer in empty sample well.

Locate thermistor probe, both horizontally and vertically, at midpoint of sample. Check location visually, using 2.5 mL H<sub>2</sub>O in sample tube.

Amplitude of stirring wire should be great enough to assure uniform temp. in sample thruout detn and may be checked visually, using 2.5 mL H<sub>2</sub>O in sample tube to which small amt of dust, powder, or dye has been added.

(App. available as Advanced Cryoscope from Advanced Instruments, Inc., 1000 Highland Ave, Needham Hts, MA 02194; as Precision Cryoscope from Precision Systems, Inc., 60 Union Ave, Sudbury, MA 01776; and as Fiske Cryoscope from Fiske Associates, Inc., Quaker Hwy, Junction Rt 146, Uxbridge, MA 01569.)

**16.101**

**Preparation of Standards**

(Use distd H<sub>2</sub>O recently boiled and cooled to 20° for prepn of stds.)

Prep. following sucrose primary stds or salt secondary stds. Det. fp values of salt stds as in (b).

(a)  $-0.406^\circ\text{C}$  ( $-0.422^\circ\text{H}$ ) *Standard*.—(1) Weigh 7.0000 g NBS std sucrose sample SRM 17 into 100 mL vol. flask and dil. to vol. with H<sub>2</sub>O; or (2) weigh 100 g H<sub>2</sub>O into 100 mL vol. flask and add 0.6892 g reagent grade NaCl (dried to constant wt just before weighing).

(b)  $-0.598^\circ\text{C}$  ( $-0.621^\circ\text{H}$ ) *Standard*.—(1) Weigh 10.0000 g NBS sucrose into 100 mL vol. flask and dil. to vol. with H<sub>2</sub>O; or (2) weigh 100 g H<sub>2</sub>O into 100 mL vol. flask and add 1.0206 g reagent grade NaCl.

(Secondary salt stds with fp values equiv. to 7 and 10% sucrose primary stds may be purchased from cryoscope manufacturers.)

Microorganisms attack sucrose after limited storage at refrigerator temps, changing fp value of primary stds. Salt (sucrose equiv.) secondary stds, stored in polyethylene bottles with screw caps, have long shelf life at room temp.; use these each time fp value detns are made. If it is suspected that salt secondary stds are in error, check them against *freshly* prepd sucrose primary stds. It is responsibility of the analyst to be certain that fp values of salt secondary stds are same as fp values of *freshly* prepd sucrose primary stds.

★ Surplus method—see inside front cover.

**16.102**

**Calibration of Cryoscope**

(See introduction to 16.099.)

Using calibration controls and fp values of stds, calibrate cryoscope to obtain correct "span" ( $0.598 - 0.406 = 0.192^\circ\text{C}$ ) and reference values ( $-0.598^\circ\text{C}$  and  $-0.406^\circ\text{C}$ ). Follow directions in manufacturer's operating manual. Calibration controls and procedures vary with make and model of cryoscope but with all instruments 2 calibration controls (A and B or I and II) are adjusted, individually or in combination, so that 7 and 10% sucrose primary stds and/or sucrose equiv. salt secondary stds yield fp values of  $-0.406^\circ\text{C}$  and  $-0.598^\circ\text{C}$ , resp., with 0.192°C span.

**16.103**

**Determination**

(If titratable acidity, 16.023, is  $>0.18\%$ , results may underest. actual amt of added H<sub>2</sub>O in sample.)

Apply following technic in exactly same manner for both stds and sample to obtain valid sample fp value.

Check cooling bath level, cooling bath temp., stirring efficiency, and probe position in sample tube as in 16.100.

Check ref. fp values and "span," using salt secondary stds or sucrose primary stds. If "span" is other than 0.192°C, recalibrate cryoscope as in 16.102. If "span" is correct but reference fp values differ from known values of stds, it is not necessary to recalibrate cryoscope; simple arithmetic correction will give correct observed fp value of sample.

Using clean, dry syringe or pipet, measure 2–3 mL sample and transfer to clean, dry sample tube supplied by manufacturer. Set measuring dial to expected fp value. Place sample tube in cooling bath sample well or in operating head and lower operating head to position sample in cryoscope cooling bath.

Cool sample if not already being cooled above. Proper cooling is indicated by rapid and uniform (steady) movement of light spot or needle from right to left over scale of galvanometer or meter.

If cryoscope raises cooling bath to sample level, begin slow cooling at  $-1.5$  to  $-2.0^\circ$ , depending on extent of supercooling desired. If cryoscope immerses sample in cooling bath, do *not* isolate sample in air above cooling bath.

Seed sample at  $-2.0$  or  $-3.0^\circ$ , depending on make of cryoscope. Galvanometer spot or meter needle will jump to right as temp. of supercooled sample rises toward fp. Extent of supercooling (seeding point) must be same for sucrose primary stds or salt secondary stds as for milk samples.

Adjust galvanometer spot or meter needle to 0 if necessary. Switch galvanometer or meter to high sensitivity position. With temp. dial, keep galvanometer or meter nulled (reading 0). Galvanometer spot or meter needle will cease to move to right, remain steady at 0, and finally begin to move to left. Read fp value from measuring dial to nearest millidegree, while spot or needle is steady just before movement to left begins. Do *not* read fp value from measuring dial at some predetd time after seeding sample; always wait for movement of galvanometer spot or meter needle to left before recording fp value. Spot or needle will become steady and begin to move to left sooner with stds than with milk samples. Check 0 point of galvanometer or meter.

**16.104**

**Interpretation**

If fp is  $-0.508^\circ\text{C}$  ( $-0.525^\circ\text{H}$ ) or below, milk *may* be presumed to be H<sub>2</sub>O-free or *may* be confirmed as H<sub>2</sub>O-free by tests specified below. If fp is above  $-0.508^\circ\text{C}$ , milk *will* be designated "presumptive added H<sub>2</sub>O" and *will* be confirmed as "added H<sub>2</sub>O" or "H<sub>2</sub>O-free" by tests specified below. Evaluate extreme daily

fluctuations in fp of herd, pooled herd, or processed milk for presence of added H<sub>2</sub>O.

To confirm herd milk as "added H<sub>2</sub>O" or "H<sub>2</sub>O-free," det. fp of authentic sample of herd milk obtained  $\leq 72$  hr after sample to be "confirmed." Authentic sample is sample of milk from 1 complete, supervised herd milking (either AM or PM but beginning not  $< 11$  or  $> 13$  hr after beginning of previous milking) obtained from bulk tank after entire herd has been milked thru approved, properly sanitized, and thoroly drained milking system into empty bulk tank but before rinsing or washing of system has begun. Compare fp of authentic sample and sample to be confirmed. If fps differ by  $\leq 0.010^\circ$ , sample is confirmed as H<sub>2</sub>O-free.

To confirm pooled herd milk as "added H<sub>2</sub>O" or "H<sub>2</sub>O-free," det. fp of authentic samples of all herd milks composing pooled herd milk, calc. weighted av. fp for the authentic samples of herd milk, and compare values as above.

To confirm processed milk as "added H<sub>2</sub>O" or "H<sub>2</sub>O-free," det. fp of samples of all pooled herd milk received by processing plant, calc. weighted av. fp for milk received, and compare with fp value to be confirmed. If fps differ by  $\leq 0.010^\circ$ , processed sample is confirmed as H<sub>2</sub>O-free during processing. If  $\geq 1$  sample of pooled herd milk is "presumptive added H<sub>2</sub>O," proceed as above for pooled herd milk. Fp for pasteurized-homogenized milk should be same as that of pooled herd milk unless processing includes vac. pasteurization, which raises fp approx.  $0.005^\circ$ .

#### Vapor Pressure Osmometric (VPO) Method (22) Official First Action

##### 16.105

##### Principle

Vapor pressure of milk sample is measured by osmometer as function of dewpoint depression. Thermocouple detector senses temp. of 5–7  $\mu$ L sample at vapor pressure equilibrium in sample chamber headspace. Readout in milliosmols (mOs)/kg H<sub>2</sub>O is converted to % added H<sub>2</sub>O in milk by comparison with readout of authenticated ref. milk samples known to be free of added H<sub>2</sub>O.

##### 16.106

##### Apparatus and Reagents

(a) *Vapor pressure osmometer.*—With either digital LED or taut band panel meter readout (Models 5100B or 5130B, Wescor, Inc., 459 S Main St, Logan, UT 84321, or equiv.). Install instrument in area relatively free from large ambient temp. changes, and adjust balance as specified in manufacturer's operating manual.

(b) *Reference milk samples.*—Authenticated to be free of added H<sub>2</sub>O, 16.104.

(c) *Thermocouple cleaning soln.*—NH<sub>4</sub>OH (1+2). Rinse cleaning soln off sample chamber with  $\geq 5$  portions  $\geq 1$  megohm distd or deionized H<sub>2</sub>O; then dry chamber using blow clean pressure vessel supplied by manufacturer or stream of filtered, compressed air. Cleaning accessory is also available from manufacturer.

(d) *Sodium chloride std soln.*—290 mOs, 0.1566M. Add 9.158 g NaCl to 1 L previously boiled and cooled H<sub>2</sub>O.

##### 16.107

##### Calibration

Using clean, dry stainless steel forceps, sat. 6.4 mm diam. filter paper (Whatman No. 1, or equiv.) by immersing 2 sec in NaCl std soln, (d). Do not dip forceps into soln. Promptly transfer satd paper to concave depression in VPO sample chamber. If sample touches outer surface of chamber, wipe dry with lint-free paper tissue and resample. Gently push sample slide into

instrument to initiate automatic time sequence. Seal sample chamber by rotating sealing knob clockwise. Adjust "Compensate 0–200" knob to 3 o'clock position and "Calibrate 1000" knob to 12 o'clock position. When tone sounds (after ca 90 sec), adjust "Calibrate 290" knob until panel meter reads 290 mOs. Repeat satn with NaCl std soln and reading in VPO with 3–4 sep. papers to assure that instrument repeatability is  $290 \pm 3$  mOs. Repeat using distd H<sub>2</sub>O, which should read 20–40 mOs. Higher readings indicate thermocouple contamination. When distd H<sub>2</sub>O reading reaches 70 mOs, clean thermocouple according to manufacturer's instructions, (c). Cleaning may be necessary after every 100–200 samples. (Caution: Thermocouple must be kept clean or large errors may result.)

##### 16.108

##### Determination

Introduce milk samples, including authenticated ref. milk samples, (b), into VPO sample chamber as in 16.107, except allow 5–6 sec to sat. paper if churned fat interferes. Clean sample chamber between samples with lint-free paper tissue contg acetone.

$$\% \text{ Added H}_2\text{O} = [(R-S)/R] \times 100,$$

where  $R$  = mOs/kg authenticated ref. milk sample known to be free of added H<sub>2</sub>O; and  $S$  = mOs/kg sample.

#### Gelatin (23)

##### 16.109 Qualitative Test—Official Final Action

(Caution: See 51.029 and 51.079.)

To 10 mL sample add 10 mL *acid-Hg(NO<sub>3</sub>)<sub>2</sub> soln* (Hg dissolved in twice its wt HNO<sub>3</sub> and this soln dild to 25 times its vol. with H<sub>2</sub>O). Shake mixt., add 20 mL H<sub>2</sub>O, shake again, let stand 5 min, and filter. If much gelatin is present, filtrate will be opalescent and cannot be obtained quite clear. To portion of filtrate in test tube add equal vol. *satd aq. picric acid soln*. Yellow ppt is produced in presence of any considerable amt of gelatin; smaller amts are indicated by cloudiness.

*Note:* In applying this test to sour, fermented, cultured, or very old samples of milk, cream, or buttermilk; to sterilized cream or evaporated milk; or to cottage cheese, use care to recognize ppts produced by picric acid when added to the Hg(NO<sub>3</sub>)<sub>2</sub> filtrates from these materials in absence of gelatin. Such samples, with or without rennet and entirely free from gelatin, give, on standing, distinct ppts when treated as above. In every case, however, these ppts differ in character from those produced by picric acid with gelatin.

Gelatin-picric acid ppt is finely divided, more apt to remain in suspension, settles only slowly, and adheres tenaciously to sides and bottom of container, from which it is rinsed with difficulty. Ppts produced by picric acid in absence of gelatin are flocculent, sep. readily (leaving serum practically clear), do not adhere to walls of container, and are easily removed by rinsing with H<sub>2</sub>O. When gelatin is present in sample, gelatin-picric acid ppt will remain in suspension long after flocculent ppt has settled, but on standing overnight the characteristic sticky deposit will be found adhering tenaciously to bottom and sides of test vessel. If gelatin is present in relatively high concn (1%), gelatin-picric acid ppt will be voluminous and will settle rather quickly.

##### 16.110 Preservatives—Official Final Action

Proceed as in Chap. 20. To test for benzoic acid or salicylic acid, acidify 100 mL milk with 5 mL HCl (1+3), shake until curdled, filter, and treat clear filtrate as in 20.020 and 20.094 or 20.095.

To test for HCHO proceed as in 20.062–20.064.

Table 16:02 Reactions with the Various Tests

Concentration of Available Cl	1:1,000	1:2,000	1:5,000	1:10,000	1:25,000	1:50,000
Test a	Yellowish brown	Deep yellow	Pale yellow, fades	—	—	—
Test b	Yellowish brown	Deep yellow	Light yellow	—	—	—
Test c	Yellowish brown	Deep yellow	Yellow	Yellow	Pale yellow	Yellowish
Test d	Blue-purple	Blue-purple	Blue-purple	Dark red-purple	Red-purple	Pale red-purple

**Hypochlorites and Chloramines (24)—Procedure**

(Unreliable in presence of &gt;2.5 ppm Cu)

**16.111****Reagents**

(a) *Potassium iodide soln.*—Dissolve 7 g KI in 100 mL H<sub>2</sub>O. Prep. fresh.

(b) *Dilute hydrochloric acid.*—To 100 mL HCl add 200 mL H<sub>2</sub>O.

(c) *Starch soln.*—Boil 1 g starch in 100 mL H<sub>2</sub>O. Cool before using.

**16.112****Tests**

(a) To 5 mL milk in test tube add 1.5 mL KI soln, mix thoroly by shaking, and note color of milk.

(b) If unaltered, add 4 mL dil. HCl, mix thoroly with flat-end stirring rod, and note color of curd.

(c) Next place tubes in large H<sub>2</sub>O bath, previously heated to 85°, and let stand 10 min (during this interval curd rises to surface); then cool rapidly by placing in cold H<sub>2</sub>O. Note color of curd and liq.

(d) Then add 0.5–1 mL starch soln to liq. below curd and note color.

**16.113 Color Additives (25)—Official Final Action**

Warm ca 150 mL milk in casserole over flame, add ca 5 mL HOAc (1+3), and continue to heat slowly nearly to bp while stirring. Gather curd, when possible, into one mass with stirring rod and pour off whey. If curd breaks up into small flecks, sep. from whey by straining thru sieve or colander. Press curd free from adhering liq., transfer to small flask, macerate with ca 50 mL ether, keeping flask tightly corked and shaking at intervals, and let stand several hr, preferably overnight. Decant ether ext into evapg dish, remove ether by evapn, and test fatty residue for annatto as follows:

Pour on moistened filter paper alk. soln of color obtained by shaking out oil or melted and filtered fat with warm 2% NaOH soln. If annatto is present, paper absorbs color, so that when washed with gentle stream of H<sub>2</sub>O it remains dyed straw color. Dry paper, add drop of 40% SnCl<sub>2</sub> soln, and again dry carefully. If color turns purple, presence of annatto is confirmed.

Curd of uncolored milk and milk colored with annatto is perfectly white after complete extn with ether. If extd fat-free curd is distinctly orange or yellowish, synthetic dye is indicated. In many cases if lump of fat-free curd in test tube is treated with little HCl, color changes to pink, indicating presence of dye similar to aniline yellow or butter yellow or perhaps one of the acid azo yellows or oranges. In such cases, sep. and identify coloring matter present in curd as in Chap. 34.

In some cases presence of synthetic dyes can be detected by directly treating ca 100 mL milk with equal vol. HCl in porcelain casserole, giving dish slight rotary motion. In presence of some dyes sepd curd becomes pink.

**16.114 Sediment Test—Official Final Action**

See 44.014–44.017.

**Residual Phosphatase**

(All glassware, stoppers, and sampling tools must be scrupulously clean. It is desirable to soak them in hot running H<sub>2</sub>O after cleaning and rinse with distd H<sub>2</sub>O. Phenolic plastic closures on reagent bottles may cause phenolic contamination and their use should be avoided.)

**16.115 ★ Method I (26)—Official Final Action ★**

Colorimetric method using Folin-Ciocalteu phenol reagent. See 15.049–15.055, 10th ed.

**Method II (27)—Official Final Action****16.116****Reagents****(a) Buffers:**

(1) *Barium borate-hydroxide buffer.*—pH 10.6±0.15 at 25°. Dissolve 25.0 g Ba(OH)<sub>2</sub>·8H<sub>2</sub>O (fresh, not deteriorated) in H<sub>2</sub>O and dil. to 500 mL. Sep. dissolve 11.0 g H<sub>3</sub>BO<sub>3</sub> and dil. to 500 mL. Warm each soln to 50°, mix solns, stir, cool to ca 20°, filter, and keep filtrate in tightly stoppered container.

(2) *Color development buffer.*—pH 9.8±0.15 at 25°. Dissolve 6.0 g Na metaborate (NaBO<sub>2</sub>) and 20 g NaCl in H<sub>2</sub>O, and dil. to 1 L with H<sub>2</sub>O.

(3) *Color dilution buffer.*—Dil. 100 mL color development buffer, (2), to 1 L with H<sub>2</sub>O.

(4) *Borax std buffer for checking pH meter.*—0.00996M, pH 9.183 at 25°, 50.007(f).

**(b) Buffer substrates:**

(1) *For evaluating pasteurization.*—Dissolve 0.10 g phenol-free cryst. disodium phenyl phosphate in 100 mL Ba borate-hydroxide buffer, (a)(1), dild (1+1). (Cryst. Na<sub>2</sub>C<sub>6</sub>H<sub>5</sub>PO<sub>4</sub> should be stored in freezing compartment of refrigerator or in desiccator.) If Na<sub>2</sub>C<sub>6</sub>H<sub>5</sub>PO<sub>4</sub> is not phenol-free, purify it as follows: Dissolve 0.5 g in 4.5 mL H<sub>2</sub>O, add 0.5 mL buffer (a)(1) and 2 drops BQC reagent, (d), and let stand 30 min. Ext color with 2.5 mL BuOH, (f), and let stand until alcohol seps. Remove alcohol with dropper and discard. Dil. 1.0 mL aq. soln to 100 mL with dil. Ba borate-hydroxide buffer, (a)(1), for prepn of buffer substrate. Heat soln at 85° for 2 min, stopper immediately, and store in refrigerator. Soln is stable 1 year if portions are withdrawn with min. exposure to atm. Develop color, and re-ext before use, if necessary.

(2) *For quantitative results with raw milk.*—Prep. as in (1), except to use 0.20 g Na<sub>2</sub>C<sub>6</sub>H<sub>5</sub>PO<sub>4</sub> or 2.0 mL purified soln.

(c) *Zinc-copper protein precipitant.*—Dissolve 3.0 g ZnSO<sub>4</sub>·7H<sub>2</sub>O and 0.6 g CuSO<sub>4</sub>·5H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL with H<sub>2</sub>O.

★ Surplus method—see inside front cover.

(d) *BQC (2,6-dibromoquinonechloroimide) soln (Gibbs reagent).*—Dissolve 40 mg BQC powder in 10 mL absolute alcohol or MeOH and transfer to dark color dropper bottle. (Reagent remains stable  $\geq 1$  month if kept in ice tray of refrigerator; do not use after it begins to turn brown. Store powd BQC in freezing compartment of refrigerator or in desiccator. (Note: Explosions of BQC reagent stored in bottles on reagent shelf have been reported.) Check new lots of BQC before use by prepg std curve with phenol and comparing curve obtained with that from lot of BQC known to be suitable. Repeat test at least semi-annually.)

(e) *Copper sulfate soln for stds.*—0.05%. Dissolve 0.05 g  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 100 mL.

(f) *Butyl alcohol.*—Use *n*-BuOH, bp 116–118°. To adjust pH, mix 1 L with 50 mL color development buffer, (a)(2). Store in g-s container.

(g) *Phenol std solns:*

(1) *Stock soln.*—Accurately weigh 1.000 g pure phenol, transfer to 1 L vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix (1 mL = 1 mg phenol). (Soln is stable several months in refrigerator.)

(2) *Working stds.*—Dil. 10.0 mL stock soln to 1 L with  $\text{H}_2\text{O}$  and mix (1 mL = 10  $\mu\text{g}$ , 0.0001 g, or 10 units of phenol). Use this std soln to prep. more dil. std solns: e.g., dil. 5, 10, 30, and 50 mL to 100 mL with  $\text{H}_2\text{O}$  to prep. std solns contg 0.5, 1.0, 3.0, and 5.0  $\mu\text{g}$  or units of phenol/mL, resp. Keep these std solns in refrigerator  $\leq 1$  week.

In similar manner prep. from stock soln std solns contg 20, 30, and 40 units/mL.

Measure appropriate vols of working std solns into series of tubes (preferably graduated at 5.0 and 10.0 mL) to provide suitable range of stds as needed, contg 0 (control or blank), 0.5, 1.0, 3.0, 5.0, 10.0, 20.0, 30.0, and 40.0 units. To increase brightness of blue solns and improve stability of std, add 1.0 mL  $\text{CuSO}_4$  soln, (e), to each tube. Then add 5.0 mL color diln buffer, (a)(3), and dil. to vol. of 10.0 mL with  $\text{H}_2\text{O}$ . Add 4 drops (0.08 mL) BQC soln, (d), mix, and let blue develop 30 min at room temp. If BuOH extn method is used, ext stds as in 16.118, Step 10(b).

Read color intensities in photometer with 610 nm filter, subtract value of blank from value of each phenol std, and prep. std curve (should be straight line).

If stds are to be used for visual comparison, store in refrigerator. Prep. new set weekly.

### 16.117

### Sampling

Mix product well, pour several mL into small tube, stopper, and keep in refrigerator. If preservative is necessary, add 1–3%  $\text{CHCl}_3$ , and label "Poison, preservative added."

### 16.118

### Determination

Chem. principles involved in detection and measurement of milk phosphatase activity are same for all dairy products, but different dairy products require modifications of methods because of their different physical properties, compositions, and especially buffering capacities.

For milk and other fluid products, proceed as follows:

*Step 1.*—Pipet 1.0 mL portions of sample into 2 or 3 tubes (1 tube is needed for control or blank; it is preferable to have 2 more tubes for duplicate detns). (For goat's milk, use 3 mL portions.)

*Step 2.*—Heat blank ca 1 min in covered beaker of boiling  $\text{H}_2\text{O}$  (temp. of entire tube must be 85–90°) and cool to room temp. From this point on, treat blank and test identically.

*Step 3.*—Add 10.0 mL Ba buffer substrate, (b)(1) or (2), stopper tube, and mix (pH 10.0 $\pm$ 0.15).

(This substrate is satisfactory for fresh milk, sweet buttermilk, or cheese whey. For old or slightly sour milk use substrate prepd

from undild buffer, (a)(1); for chocolate drinks, prep. substrate from buffer dild with  $\frac{1}{4}$  vol.  $\text{H}_2\text{O}$ ; for very acid (pH <4.5) buttermilk, prep. substrate from 26-11 buffer, 16.275(a)(2); and for goat's milk, prep. substrate from 27-11 buffer, 16.275(a)(2).

For quant. results on unknown samples, adjust pH to 10.0–10.05.

*Step 4.*—Immediately after adding substrate, incubate in  $\text{H}_2\text{O}$  bath 1 hr at 37–38°, mixing or shaking contents occasionally.

*Step 5.*—Heat in beaker of boiling  $\text{H}_2\text{O}$  nearly 1 min. (Temp. of contents of tubes should reach 85–90°, as detd by thermometer in another tube of same size and shape contg same vol. liq.) Cool to room temp. in vessel of cold  $\text{H}_2\text{O}$ .

*Step 6.*—Pipet in 1.0 mL Zn-Cu protein precipitant, (c), for fresh milk, sweet buttermilk, or cheese whey. (For old or slightly sour milk or acid buttermilk, substitute 1.0 mL 6.0%  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$  soln; for chocolate drinks, use 1.0 mL of soln contg 4.5 g  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$  and 0.1 g  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ /100 mL; and for goat's milk, use 1.0 mL of soln contg 7.5 g  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$  and 0.1 g  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ /100 mL.) Mix thoroly (pH of mixt. should be 9.0–9.1).

*Step 7.*—Filter (5 cm funnel, 9 cm Whatman No. 42 or No. 2 paper, or equiv.) and collect 5.0 mL filtrate in tube, preferably graduated at 5.0 and 10.0 mL.

*Step 8.*—Add 5.0 mL color development buffer, (a)(2), (pH of mixt. should be 9.3–9.4).

*Step 9.*—Add 4 drops BQC soln, (d), mix, and let color develop 30 min at room temp. (For merely detecting underpasteurization, add only 2 drops of the BQC soln.)

*Step 10.*—Det. intensity of blue color by one of following methods:

(a) *With photometer.*—Read color intensities of blank and test solns (using filter with max.  $T$  ca 610 nm), subtract reading of blank from that of test, and convert result to phenol equivs by ref. to std curve, (g)(2). [Ordinarily BuOH extn is unnecessary when photometer is used; if BuOH extn is made as in (b), centrf. sample 5 min to break emulsion and remove  $\text{H}_2\text{O}$  suspended in alcohol layer. (Babcock centrf. can be adapted for this purpose by making special tube holders as follows: Slice section 6 mm thick from rubber stopper of suitable diam. to fit into bottom of centrf. cup. Glue together 2 cork stoppers of appropriate diam., bore thru center a hole of proper size to hold tube snugly, and insert double cork section into cup.) After centrfg, remove nearly all BuOH by pipet with rubber bulb on top end. Filter into photometer cell and read with filter with max.  $T$  ca 650 nm.]

(b) *With visual stds.*—With samples yielding >5 units, compare colors in tubes with those of aq. phenol stds, (g)(2). For quant. results in borderline instances, (e.g., tests yielding 0.5–5 units of color), ext with BuOH, (f). Add 5.0 mL of BuOH and invert tube slowly several times; centrf. as in (a) if necessary to increase clearness of alcohol layer, and compare blue with colors of phenol stds, (g)(2), similarly treated.

*Step 11.*—In tests observed to be strongly pos. during color development (e.g.,  $\geq 20$  units), in which 4 drops of BQC soln may be insufficient to combine with all the phenol, pipet appropriate proportion of contents into another tube, dil. to 10.0 mL with color diln buffer, (a)(3), and add 2 addnl drops BQC soln. With each test, dil. and treat blank similarly. If test on dild sample is still very strongly pos., dil. again in same manner until final color is within range of visual stds or photometer std curve. Allow 30 min for color development after last addn of BQC soln before making final reading. To correct reading for diln, multiply by 2 for 5 + 5 diln, by 10 for 1 + 9 diln, and by 50 for 1 + 9 diln followed by 2 + 8 diln, etc.

*Step 12.*—When using 1.0 mL sample and adding 11.0 mL reagents (total liq. 12.0 mL, 5.0 mL filtrate used), multiply value of reading by 1.2 to convert to phenol equivs/0.5 mL sample.

(If desired, results may be converted to phenol equivs/1 mL by multiplying by 2.4.) Phenol equivs  $>2/0.5$  mL indicate underpasteurization in cow's milk, chocolate drinks, buttermilk, and cheese whey; phenol equivs  $>1/1.5$  mL indicate underpasteurization in goat's milk.

*Notes:* To test concd milk products, reconstitute product with H<sub>2</sub>O to original concn of milk solids and test in manner specified for original product.

See also *Notes* in 16.277.

#### 16.119 ★ *Method III (28)—Official Final Action* ★

Residual phosphatase liberates free phenol within cellulose bag. Phenol diffused thru membrane is detd colorimetrically. See 16.104–16.107, 12th ed.

#### *Method IV (29)—Official Final Action*

##### 16.120

##### *Principle*

Milk is incubated 3 hr with phthln monophosphate in carbonate buffer at pH 9.6. Free phthln is liberated by residual alk. phosphatase of milk and passes thru membrane along with buffer and other solutes into H<sub>2</sub>O, resulting in clear dialysate which can be measured directly in spectrophtr.

##### 16.121

##### *Reagents*

(a) *Phenolphthalein monophosphate soln (substrate concentrate)*.—pH 10.15 at 25°. Dissolve 3.9 g dicyclohexylamine salt of phthln monophosphate and 73.2 g 2-amino-2-methyl-1-propanol in 21.9 mL HCl. Soln is stable indefinitely under refrigeration. (Available as Phosphastrate® Alkaline from General Diagnostics Div., Warner-Chilcott Laboratories, 201 Tabor Rd, Morris Plains, NJ 07950.)

(b) *Sodium sesquicarbonate dihydrate buffer soln*.—Dissolve 10 g NaHCO<sub>3</sub>·Na<sub>2</sub>CO<sub>3</sub>·2H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL.

(c) *Dialyzing, seamless cellulose tubing*.—Available as "Dialysis Membrane" from Union Carbide Corp., Films-Packaging Div., 6733 W 65 St, Chicago, IL 60638. Order No. 27 DC; 0.0009" wall thickness, width flat 1.31", diam. round 21 mm, 100' random lengths. Cut enough 20 cm lengths of tubing and immerse in H<sub>2</sub>O  $\geq 30$  sec. Remove, and wrinkle one end with fingers. Twist and tie this end tightly into leakproof knot, and cut off excess cellulose beyond knot with scissors. Store bags in H<sub>2</sub>O until ready to use. Tubing may require several rinsings with H<sub>2</sub>O to remove surface film. During use, take precautions against phenol or enzyme contamination from contact with fingers or phenol-contg substances, e.g., plastics.

(d) *Phenolphthalein stock std soln*.—100  $\mu$ g/mL. Dissolve 100 mg fresh phthln in 1 L 50% alcohol.

##### 16.122

##### *Preparation of Standard Curve*

Pipet 0.0, 0.1, 0.2, 0.3, 0.5, 0.7, and 1.0 mL phthln stock soln into sep. 15  $\times$  100 mm test tubes. Add amt buffer soln to bring vol. to 10 mL in each tube. (Final phthln concns are 0.0, 1.0, 2.0, 3.0, 5.0, 7.0, and 10.0  $\mu$ g/mL, resp.) Mix, and det. A at 550 nm. Plot A against  $\mu$ g phthln/mL.

##### 16.123

##### *Determination*

Pipet 3 mL milk into 15  $\times$  100 mm test tube and temper 3–5 min in 37° H<sub>2</sub>O bath. Add 3 drops (0.04 mL/drop) substrate conc. to tube and mix thoroly, preferably with mech. mixer. Prep. and incubate blank similarly, using milk heated 2 min at 80°.

Insert short-stem funnel (35  $\times$  75 mm), into presoaked, knotted

dialysis bag, transfer sample mixt., press air out of bag, and knot top end tightly. Rinse outside with H<sub>2</sub>O and dry lightly with paper towel. Immediately suspend bag in 20  $\times$  100 mm test tube contg 5 mL H<sub>2</sub>O, stopper (No. 3 rubber stopper), and incubate 3 hr in 37° H<sub>2</sub>O bath. (Contents of bag *must* be completely immersed in H<sub>2</sub>O but top knot *must not* contact soln to avoid possible contamination of dialysate with milk.)

Remove bag from tube and discard. Read A of dialysate at 550 nm, using dialysate from heated milk sample to set instrument at 100% T. Calc. phthln concn from std curve.

##### 16.124

##### *Interpretation*

Reading of  $>1.15$   $\mu$ g phthln/3 mL milk indicates underpasteurization or contamination of milk with raw milk.

#### *Method V (30)—Official First Action*

##### 16.125

##### *Reagents*

(a) *Carbonate buffer*.—Dissolve 46.89 g Na<sub>2</sub>CO<sub>3</sub> and 37.17 g NaHCO<sub>3</sub> in H<sub>2</sub>O and dil. to 1 L with H<sub>2</sub>O.

(b) *Buffer substrate*.—Dissolve 0.5 g phenol-free cryst. disodium phenyl phosphate in H<sub>2</sub>O, add 25 mL of buffer, (a), and dil. to 500 mL with H<sub>2</sub>O. If Na<sub>2</sub>C<sub>6</sub>H<sub>5</sub>PO<sub>4</sub> is not phenol-free, purify as follows: Place 0.5 g in separator and dissolve in 10 mL H<sub>2</sub>O. Add 25 mL buffer, (a), and 2–3 drops CQC contg catalyst, (d). Mix, and let stand 5 min. Ext color with 5 mL BuOH, (e), and let stand until alcohol seps. Remove bottom aq. layer into 500 mL vol. flask and dil. to vol. with H<sub>2</sub>O. *Prep. fresh daily.*

(c) *CQC soln*.—Dissolve 40 mg cryst. 2,6-dichloroquinone-chloroimide in 10 mL absolute alcohol or MeOH and transfer to dark bottle. Or, prep. soln by dissolving 1 Indo-Phax tablet (contg catalyst) (available from Applied Research Institute, 90 Brighton Ave, Perth Amboy NJ 08861) in 5 mL alcohol or MeOH. Store soln in refrigerator. Discard after 1 week or when brown.

(d) *Catalyst*.—Dissolve 200 mg CuSO<sub>4</sub>·5H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL.

(e) *Butyl alcohol*.—Use *n*-BuOH, bp 116–118°. To adjust pH, mix 10 mL buffer, (a), and 40 mL H<sub>2</sub>O with 1 gal. (3.8 L) BuOH. Store in refrigerator in dark bottle.

(f) *Phenol std solns*.—(1) *Stock soln*.—Accurately weigh 1.000 g pure phenol, transfer to 1 L vol. flask, dil. to vol. with 0.1N HCl, and mix (1 mL = 1 mg phenol). Soln is stable several months in refrigerator. (2) *Working stds*.—Dil. 5 mL stock soln to 500 mL with H<sub>2</sub>O and mix (1 mL = 10  $\mu$ g phenol). Dil. 0.0, 0.5, 1.0, 2.5, and 5.0 mL to 5.0 mL with H<sub>2</sub>O to prep. std solns contg 0.0, 1.0, 2.0, 5.0, and 10.0  $\mu$ g phenol equivs/mL, resp. *Prep. fresh daily.*

(g) *Color std solns*.—Prep. working std solns in series of tubes, add 0.1 mL CQC soln, (c), and 2 drops catalyst, (d), or use 0.1 mL Indo-Phax soln, (c). Mix well, and incubate 5 min at 40°. Remove from bath, cool, and ext with 3 mL BuOH as in 16.126.

##### 16.126

##### *Determination*

Pipet 0.5 mL of well mixed sample into test tubes (1 tube needed for boiled control or blank). Add 5 mL buffer substrate soln and mix. Immediately incubate in H<sub>2</sub>O bath 15 min at 40° (allow 1 min warm-up time for a total of 16 min), mixing samples at least once during warm-up time. Remove from H<sub>2</sub>O bath, add 0.1 mL CQC soln, and 2 drops catalyst, or 0.1 mL Indo-Phax soln (contains catalyst). Mix, and immediately place in H<sub>2</sub>O bath 5 min, mixing contents at least once. Remove from bath and cool in ice-H<sub>2</sub>O bath 5 min. Add 3 mL BuOH and ext by inversion 6 full turns. Let stand in ice-H<sub>2</sub>O bath 5 min. Centrif. 5 min. Remove BuOH layer into cuvetts with Pasteur pipet. Det. A of BuOH layer against 0 phenol color std, and calc. phenol equivs.

★ Surplus method—see inside front cover.

Read *A* of BuOH exts of color std solns, using red filter in colorimeter or with spectrophtr set at 650 nm. Std curve of  $\mu\text{g}$  phenol against *A* should be straight line.

**Qualitative (Screening) Method (31)—Official Final Action**

(Applicable to skim and whole milk and light cream)

**16.127**

**Reagents**

(a) *Phenolphthalein monophosphate soln* (substrate concentrate).—See 16.121(a).

(b) *Phenolphthalein-tartrazine soln* (std concentrate).—0.01 and 0.04% by wt, resp.; pH 10.15 at 25°. Dissolve 10 mg phthln, 40 mg tartrazine, and 73.2 g 2-amino-2-methyl-1-propanol in 21.9 mL HCl. Soln is stable indefinitely under refrigeration.

(c) *Color developer*.—2.5*N* NaOH.

**16.128**

**Determination**

Pipet 1 mL milk into each of two 15 × 100 mm test tubes and warm to 37°. To 1 tube add 1 drop (0.04 mL) substrate conc. (pH of incubation mixt. 10.0) and to other add 1 drop std conc. Mix and incubate 30 min at 37°. Add 1 drop 2.5*N* NaOH to each tube, mix, and compare visually. If sample soln (in tube contg substrate conc.) is less pink than std soln, milk has been pasteurized to extent equiv. to <0.1% raw milk.

**Reactivated and Residual Phosphatase,  
Differential Test (32)—Official First Action**

**16.129**

**Reagent**

*Magnesium acetate soln*.—40.1 g Mg/mL. Dissolve 35.4 g  $\text{Mg}(\text{OAc})_2 \cdot 4\text{H}_2\text{O}$  in 25 mL  $\text{H}_2\text{O}$ , warming slightly. Transfer quant. to 100 mL vol. flask with  $\text{H}_2\text{O}$ , cool, and dil. to 100 mL.

**16.130**

**Reactivation**

Place 10 mL of each sample in boiling  $\text{H}_2\text{O}$  bath and hold 1 min after temp. of sample reaches 95°. Cool, and use portion of each for diln, as required, and for boiled control. Place 5 mL aliquot of sample in screw-cap (phenol-free) test tube. Add 0.1 mL  $\text{H}_2\text{O}$ . To second 5 mL aliquot in identical tube add 0.1 mL  $\text{Mg}(\text{OAc})_2$  soln. Incubate both tubes 1 hr at 34°. Remove samples from bath and cool in ice- $\text{H}_2\text{O}$  bath. Dil. aliquot of 1 mL sample contg Mg with 5 mL of corresponding boiled control. Test undild sample contg no Mg and 1+5 diln contg Mg for phosphatase activity as in 16.118, 16.123, 16.126, or 16.164, keeping tubes cool until analysis.

If 1 + 5 diln contg Mg has equal or greater phosphatase activity than undild sample contg no Mg, sample is regarded as neg. for residual phosphatase and indicates that phosphatase originally measured is of reactivated origin. If dild sample contains less activity than undild sample, it is considered pos. for residual phosphatase provided that initial conventional phosphatase test was pos. False pos. test for residual phosphatase may be obtained if reactivatable sample stood at elevated temp. (21–24°; 70–75°F) for  $\geq 2$  hr.

**PENICILLINS IN MILK**

***Bacillus Stearothermophilus* Qualitative Disc Method (33)  
Official First Action**

**16.131**

**Culture Media**

(a) *Agar medium B*.—See 42.196(b).

(b) *Agar medium M*.—Dissolve 15.0 g pancreatic digest of casein, 5.0 g papaic digest of soybean, 5.0 g NaCl, and 15.0 g agar in  $\text{H}_2\text{O}$  and dil. to 1 L. Adjust if necessary so that after

sterilization pH is  $7.3 \pm 0.2$ . (BBL Trypticase Soy Agar has been found satisfactory.)

(c) *Broth medium C*.—Dissolve 17.0 g pancreatic digest of casein, 3.0 g papaic digest of soybean, 5.0 g NaCl, 2.5 g  $\text{K}_2\text{HPO}_4$ , and 2.5 g dextrose in  $\text{H}_2\text{O}$ , and dil. to 1 L. Adjust if necessary so that after sterilization pH is  $7.3 \pm 0.2$ . (BBL Trypticase Soy Broth has been found satisfactory.)

**16.132**

**Reagent and Apparatus**

(a) *Penicillin stock soln*.—Accurately weigh, in atm. of  $\leq 50\%$  relative humidity, ca 30 mg USP K (or Na) penicillin G Ref. Std. Dissolve in enough pH 6 buffer, 42.197(f), to give known concn of 100–1000 units/mL. Store in dark  $\leq 2$  days at 2–10°.

(b) *Penicillinase (beta-lactamase)*.—Preps are available from Difco Laboratories; BBL; ICN Nutritional Biochemicals, 26201 Miles Road, Cleveland, OH 44128; Schwarz/Mann, Orenbury, NY 10962; and Calbiochem. Penicillinase preps are not stdzd. It is therefore important to choose prep of sufficient strength to ensure complete inactivation of antibiotic soln under test.

(c) *Control disks*.—Prep. fresh daily from pos. control milks contg 0.008 and 0.005 unit/mL as in 16.138(b).

(d) *Petri dishes (plates)*.—See 42.198(b).

**16.133**

**Stock Culture of Test Organism**

Maintain *B. stearothermophilus* (ATCC 10149) on agar medium M, (b), transferring to fresh slant weekly. Inoculate slant of agar medium M with test organism and incubate overnight at 55°. Inoculate three 300 mL erlenmeyers, each contg 150 mL broth medium C, (c), with 1 loopful of test organism. Incubate at 55° and periodically make spore stains to det. extent of sporulation. When ca 80% sporulation has occurred (usually in 72 hr), centr. cell suspension 15 min at 2000 rpm. Decant supernate, resuspend cells in saline soln, 42.197(r), and recentrif. Repeat saline washing. Resuspend washed cells in 30 mL saline and store at 4°. Spore suspension will remain viable 6–8 months. Check viability periodically by prep of trial test plates.

**16.134**

**Preparations of Plates**

Inoculate aliquot of liquified agar medium B, (a), cooled to 55° with previously prepd spore suspension (usually 1–2 mL/100 mL agar medium). Adjust inoculum level to provide clear, readable zones of inhibition from penicillin pos. control disks, (c), after 3–4 hr incubation. Pour 8 mL inoculated agar medium B into each plate, and let harden on flat, level surface.

**16.135**

**Assay**

Thaw frozen milk samples at room temp. Subdivide each sample into 2 portions and add penicillinase, (b), to one portion (ca 0.1 mL/5 mL milk). Test both milk portions. Using forceps, touch paper disk to surface of milk and let milk be adsorbed by capillary action. Drain excess milk by touching disk to inside surface of sample vessel. Place 6 disks (one disk from penicillinase-treated sample and one from untreated portion of same sample for each of 2 samples) and 2 std penicillin pos. control disks (0.005 and 0.008 unit/mL). Prep. duplicate plates for each assay. Invert plates and incubate 3–4 hr at 55° or until visible zones of inhibition appear. Read by holding plates up to diffuse light source and measure diams of zones of inhibition.

**16.136**

**Interpretation**

Penicillinase inactivation of test soln may produce following results:

(1) *Complete inactivation (positive test)*: Loss of activity of

treated versus untreated aliquot of sample soln indicates that *beta*-lactam residue was present.

(2) *Incomplete inactivation (presumptive test)*: Significant reduction in activity of treated versus untreated aliquots of sample soln indicates that *beta*-lactam residue was present, but that other active agents or ingredients have caused interference problems.

(3) *No inactivation (false test)*: No significant reduction in activity of treated versus untreated aliquots of sample soln indicates that interfering agents or ingredients may be masking presence of *beta*-lactam residue. No qual. analysis can be made of residue.

(4) *No activity (neg. test)*: Absence of zones of inhibition from treated and untreated aliquots of sample soln indicates that no *beta*-lactam residue(s) has been detected (within limitations of test method).

Penicillin pos. control soln at 0.008 unit/mL level should produce clear, well-defined zones of inhibition. Penicillin pos. control at 0.005 unit/mL may or may not produce discernible zones of inhibition and degree of activity produced by this 0.005 unit/mL level may vary from one day to another. If no zones of inhibition are produced by either of penicillin pos. control solns, adequate test sensitivity has not been obtained and test should be repeated.

*B. stearothermophilus* disk method has been used successfully for qual. detection of residues of penicillin G, at 0.005–0.008 unit/mL, ampicillin and cephalixin at 0.005–0.008 µg/mL, and cloxacillin at 0.05–0.08 µg/mL.

#### ***Bacillus subtilis* Qualitative Field Disk Assay (34) Official Final Action**

(Sensitive to ca 0.05 unit/mL)

#### **16.137**

#### **Culture Media**

(a) *Agar medium A*.—For carrying test organism and for performing assay. See 42.196(a).

(b) *Agar medium G*.—For prepg test suspension. See 42.196(g).

#### **16.138**

#### **Reagents**

(a) *Stock penicillin soln*.—Accurately weigh, in atm. of ≤50% relative humidity, ca 10 mg USP K (or Na) Penicillin G Ref. Std. Dissolve in enough pH 6 buffer, 42.197(f), to give concn of exactly 100 units/mL. Store in dark at ca 5° ≤2 days.

(b) *Control disks*.—Dil. stock penicillin soln with antibiotic-free, whole, homogenized milk to final concns of 0.05 and 0.1 unit/mL. Use S&S 740E ¼" disks or prep. ¼" round, white disks from S&S 470W or 470 paper, of equiv. absorption performance qualities and purity. Dip disks into std penicillin-contg milks and shake off excess. Dry on rust-proof wire screening under fan. Stored in refrigerator in tightly stoppered vial with desiccant, disks are usable 1 month.

#### **16.139**

#### **Stock Culture of Test Organism**

Maintain *Bacillus subtilis* on agar medium A, transferring to fresh slant monthly. Inoculate fresh slant of agar medium A with test organism and incubate 16–24 hr at 37°. Wash culture from slant with 2–3 mL sterile 0.9% NaCl soln with aid of sterile glass beads onto surface of Roux bottle contg 300 mL agar medium G. Incubate 5 days at 37°. Wash resulting growth from surface with aid of the beads and 50 mL sterile 0.9% NaCl soln into sterile centrf. tube, centrf., and decant supernate. Reconstitute sediment with ca 70 mL sterile 0.9% NaCl soln and heat-shock spore suspension by heating 30 min at 70°. Store in g-s flask in refrigerator. Suspension is stable several months.

With each new suspension, det. amt to be used as follows: Prep. plates as directed below with varying amts of inoculum, i.e., 0.2, 0.5, 1.0, and 2.0 mL/100 mL medium. Refrigerate 3–5 days. Place control disks of 0.05 and 0.1 unit/mL on plates and incubate as in test. Use as concn of inoculum that concn showing best response, considering both sensitivity and discernibility of zones of inhibition.

#### **16.140**

#### **Preparation of Plates**

Melt agar medium A, cool to 55–60°, and add 0.2–2.0 mL spore suspension, 16.139, to each 100 mL agar medium A. Mix well.

Add 10 mL inoculated agar to each 20 × 100 mm glass or plastic petri dish. Distribute agar evenly, cover with porcelain covers glazed only on outside, and let harden on level surface. Store in refrigerator ≥3 but ≤5 days. Remove each dish from refrigerator as needed and use within 15 min.

#### **16.141**

#### **Assay**

With forceps place 0.05 and 0.1 unit/mL control disks on each plate.

Thoroughly shake each milk sample to disperse fat evenly. Using forceps, dip blank disk completely into sample, withdraw, and shake off excess milk by vigorously waving in air several times. Place disk on surface of agar and touch gently with tip of forceps to assure proper contact. *Do not touch so heavily that milk is squeezed out of disk*. Place disks so that they are ≥20 mm apart, measured center to center, to avoid overlapping of zones. Flame tips of forceps to avoid carryover from contaminated samples. Place control and sample disks on plate within few min of one another.

Incubate plates 2.5–3 hr at 37°, and examine for zones of inhibition. Hold plates at various angles to light (either elec. bulb or daylight) to det. optimum conditions for observation. Zones around control disks indicate sensitivity of test.

To det. if zone of inhibition is due to penicillin, add 0.05 mL (ca 1 drop) *penicillinase conc.* (BBL or Difco penicillinase have been found satisfactory) to 5 mL aliquot milk sample and shake well. Prep. 3 disks from this treated sample and from untreated sample. Place all disks on same plate, incubate as before, and observe. Zone around untreated sample disks but no zone around treated sample disks is pos. test for penicillin. Zone of inhibition around both treated and untreated sample disks indicates antibacterial activity other than penicillin.

#### **16.142**

#### **Quantitative Overnight Method**

Use method for penicillin in feed, 42.278–42.281, prepg std solns for std curve with antibiotic-free, whole, homogenized milk instead of pH 6 buffer. Cylinders must be used for application of samples and stds for detection of as little as 0.01 unit penicillin/mL. Disk method of application, 16.141, instead of cylinders may be used for concns >0.025 unit/mL. Milk sample is assay soln unless concn >0.2 unit/mL is anticipated, in which case dil. sample with antibiotic-free milk to estd concn of 0.05 unit/mL.

#### **16.143 Vitamin D in Milk—Official Final Action**

See 43.195–43.208.

#### **CREAM**

#### **16.144 Collection of Sample—Procedure**

(See also 16.001–16.007.)

Proceed as in 16.019. Promptly analyze sample, preferably within 3 days after collection.

**16.145 Preparation of Sample—Procedure**

Immediately before withdrawing test portions, mix sample by shaking, pouring, or stirring (or use hand homogenizer) until it pours readily and uniform emulsion forms. If sample is very thick, warm to 30–35° and mix. In case lumps of butter have sep'd, heat sample to ca 38° by placing in warm H<sub>2</sub>O bath. (Temp. appreciably >38° may cause fat to "oil off," especially in case of thin cream.) Thoroughly mix portions for analysis and weigh immediately. (In com. testing for fat by Babcock method, it may be advisable to warm all samples to ca 38° in H<sub>2</sub>O bath previous to mixing.)

**16.146 Preparation of Sample of Pressurized Cream (35)—Official Final Action**

Place containers in freezer overnight to freeze contents. Release as much gas as possible from frozen contents thru nozzle, holding container upright. Refreeze if necessary. Open container, using can opener on nonreturnable type or wrench on heavier, returnable type. Empty contents into weighed 1 L jar of high-speed blender, and weigh to 0.1 g. Let thaw (complete thawing is not necessary). Beat to smooth, creamy liq., keeping blender covered. Beat intermittently to prevent overheating sample and blender. (Process may require 15 min. "Butter" stage is intermediate, and beating must be continued until this stage is passed.) When sufficiently mixed, weigh blender jar and contents again. Calc. % loss in wt and apply this correction to subsequent detns. Weigh samples for fat, solids, sucrose, or other analyses, beating few sec between withdrawals of samples.

**16.147 Lactic Acid—Official Final Action**

See 16.027–16.031.

**16.148 Water-Insoluble Fatty Acids (36) Official Final Action**

Weigh 50 g prepd sample, 16.145, into 250 mL centr. bottle, add 20 mL alcohol, shake, and add 50 mL ether. Proceed as in 16.220, par. 2, except use 10 mL Na<sub>2</sub>WO<sub>4</sub> soln. (When Na<sub>2</sub>WO<sub>4</sub>-treated mixt. is shaken with ether, emulsions may form and not break completely on centrfg. These emulsions may be broken by adding 10–20 mL alcohol, mixing gently, and again centrfg.)

**16.149 ★ Rapid Method—Official First Action ★**

See 16.208–16.210, 12th ed.

**16.150 Volatile Acids (37)—Official Final Action**

Weigh 100 g sample into 250 mL vol. flask, add 100 mL H<sub>2</sub>O and 2 mL H<sub>2</sub>SO<sub>4</sub> (1+1), and mix, avoiding violent shaking. Add 15 mL 10% Na<sub>2</sub>WO<sub>4</sub>·2H<sub>2</sub>O soln, dil. to vol., mix, and filter thru rapid paper. Transfer 150 mL filtrate to distn flask and proceed with distn, chromatgc sepn, and detn as in 18.054–18.058 or 18.059. Calc. to mg acids/100 g fat.

See 14.099–14.101 for identification of volatile acids.

**16.151 Total Solids—Official Final Action**

Proceed as in 16.032, using 2–3 g sample.

**16.152 ★ Added Water (38)—Official Final Action ★**

Hortvet cryoscope method. See 16.086–16.088, 12th ed.

**16.153 Ash—Official Final Action**

See 16.035.

**16.154 Total Nitrogen—Official Final Action**

See 16.036.

**Lactose****16.155 Gravimetric Method—Official Final Action**

See 16.057.

**Fat****16.156 Roese-Gottlieb Method—Official Final Action**

Using 5 g sample and dilg with H<sub>2</sub>O to ca 10.5 mL, proceed as in 16.059, beginning "Add 1.25 mL NH<sub>4</sub>OH . . ."

**Babcock Method—Official Final Action****16.157****Apparatus**

(a) *Test bottles*.—Std Babcock cream-test bottles are as follows:

(1) *50%, 9 g, short-neck, 6" cream-test bottle*.—Total ht 150–165 mm (5.9–6.5"). Bottom of bottle must be flat, and axis of neck vertical when bottle stands on level surface. Amt of cream for bottle is 9 g.

*Bulb*.—Capacity of bulb to junction with neck is ≥45 mL. Bulb may be either cylindrical or conical. If cylindrical, od must be 34–36 mm; if conical, od of base must be 31–33 mm, and max. diam., 35–37 mm.

*Neck*.—Cylindrical and of uniform diam. from ≥5 mm below lowest graduation mark to ≥5 mm above highest. Top of neck is flared to diam. of ≥15 mm. Graduated portion of neck is ≥63.5 mm long. Total % graduation is 50. Graduations shall represent 5, 1, and ½%, resp., from 0.0 to 50%. 5% graduations must extend at least half-way around neck to right; ½% graduations must be ≥3 mm long; and 1% graduations must be intermediate in length between 5% and ½% graduations and project 2 mm to left of ½% graduations. Each 5% graduation must be numbered (thus: 0, 5, 10, . . . 45, 50), number being placed to left of scale. Capacity of neck for each whole % on scale must be 0.1 mL. Max. error in total graduation or any part thereof must not exceed vol. of smallest unit of graduation.

(2) *50%, 9 g, long-neck, 9" cream-test bottle*.—Same specifications as in (1), except that total ht of this bottle is 210–229 mm (8.25–9.0") and graduated portion of neck has length of ≥120 mm.

(3) *50%, 18 g, long-neck, 9" cream-test bottle*.—Same specifications as in (2), except that amt of cream for this bottle is 18 g.

Each bottle must bear on top of neck above graduations, in plain legible characters, mark denoting wt sample to be used, viz., "9 g" or "18 g," as case may be.

Each bottle must be constructed so as to withstand stress to which it will be subjected in centrfg.

(4) *Testing*.—Proceed as in 16.060(a)(3).

(b) *Water bath for cream samples*.—Provided with thermometer and control to maintain temp. of 38°.

(c) *Cream weighing scales*.—With sensibility reciprocal of 30 mg, i.e., addn of 30 mg to either pan of scale, when loaded to capacity, causes deflection of ≥1 subdivision of graduation. Set scales level upon support and protect from drafts.

(d) *Weights*.—9 g and 18 g, resp., and plainly marked "9 g" or "18 g," as case may be. Must be made of material capable of resisting corrosion or other injury, and preferably of low squat shape, with rounded edges. Verify them at frequent intervals by comparison with stdzd wts.

(e) *Acid measure*.—See 16.060(c).

★ Surplus method—see inside front cover.

- (f) *Centrifuge or "tester."*—See 16.060(d).  
 (g) *Dividers or calipers.*—See 16.060(e).  
 (h) *Water bath for test bottles.*—See 16.060(f).

**16.158****Determination**

Weigh 9 g prepd sample, 16.145, directly into 9 g cream-test bottle, or 18 g into 18 g bottle, and proceed by one of following methods.

(a) *Method 1.*—After weighing cream into test bottle, add 8–12 mL  $\text{H}_2\text{SO}_4$  (sp gr 1.82–1.83 at 20°) to 9 g bottle; or 14–17 mL to 18 g bottle; or add acid until mixt. of cream and acid, after shaking, is chocolate-brown. Shake until all lumps completely disappear and add 5–10 mL soft  $\text{H}_2\text{O}$  at 60° or above. Transfer bottle to centr., counterbalance it, and after proper speed is reached, centr. 5 min. Add soft hot  $\text{H}_2\text{O}$  until liq. column approaches top graduation of scale; then centr. 1 min longer at 55–60°. Adjust temp. as in 16.061, and with aid of dividers or calipers measure fat column, in terms of % by wt, from lower surface to bottom of upper meniscus.

(b) *Method 2.*—For 9 g bottle only.—After weighing cream into test bottle, add 9 mL soft  $\text{H}_2\text{O}$  and mix thoroly; add ca 17.5 mL of the  $\text{H}_2\text{SO}_4$  and shake until all lumps completely disappear. Transfer bottle to centr., counterbalance it, and after proper speed is reached, centr. 5 min. Fill bottle to neck with hot  $\text{H}_2\text{O}$  and centr. 2 min. Add hot  $\text{H}_2\text{O}$  until liq. column approaches top graduation of scale, and centr. 1 min longer at 55–60°. Adjust temp. and measure fat column as in (a).

Whichever method is followed, fat column, at time of reading, should be translucent, golden yellow to amber, and free from visible suspended particles. Reject all tests in which fat column is milky or shows presence of curd or of charred matter, or in which reading is indistinct or uncertain; repeat test, adjusting amt of  $\text{H}_2\text{SO}_4$  added.

If desired, add glymol or pure white mineral oil (sp gr  $\leq 0.85$  at 20°). Introduce only few drops into bottle just before reading is made, letting it flow down inside of neck. For purpose of measurement, surface sepg glymol and fat is regarded as representing upper limit of column. Oil-sol. artificial color may be added to the white mineral oil.

**16.159 Gelatin—Official Final Action**

See 16.109. Observe *Note*.

**16.160 Preservatives—Official Final Action**

See 16.110 and Chap. 20.

**16.161 Color Additives—Official Final Action**

See 16.113 and Chap. 34.

**Residual Phosphatase—Official Final Action****16.162 ★ Method I ★**

Folin-Ciocateu colorimetric method. See 15.049–15.055, 10th ed.

**Method II (27)****16.163****Reagents and Sampling**

See 16.116 and 16.117.

**16.164****Determination**

Proceed as in 16.118, except for following:

In *Step 1*, use 1.0 g instead of 1 mL sample if desired.

In *Step 3*, treat fresh cream in same manner as fresh milk; for old or slightly sour cream use 8 mL of the Ba borate-hydroxide buffer, 16.116(a)(1), and 2 mL  $\text{H}_2\text{O}$ .

In *Step 6*, treat fresh cream in same manner as fresh milk; for old or slightly sour cream substitute 1.0 mL 4.5 g/100 mL soln  $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$  for the Zn-Cu precipitant.

Phenol equivs  $> 2/0.5$  mL or 0.5 g indicate underpasteurization.

**16.165 Reactivated and Residual Phosphatase  
Official First Action**

See 16.129–16.130.

**EVAPORATED MILK (UNSWEETENED)****16.166 Sampling—Official Final Action**

See 16.001–16.005 and 16.008–16.009.

**16.167 Preparation of Sample (39)—Procedure**

(FAO/WHO method. See *Introduction*, 16.059.)

(a) Temper unopened can in  $\text{H}_2\text{O}$  bath at ca 60°. Remove and vigorously shake can every 15 min. After 2 hr, remove can and let cool to room temp. Remove entire lid and thoroly mix by stirring contents in can with spoon or spatula. (If fat seps, sample is not properly prepd.)

(b) Dil. 40 g prepd mixt. (a) with 60 g  $\text{H}_2\text{O}$  and mix thoroly.

**16.168 Lactic Acid—Official Final Action**

See 16.027–16.031.

**16.169 Total Solids (5)—Official Final Action**

Proceed as in 16.032, using 4–5 g dild sample, 16.167(b). Correct result for diln.

**16.170 Ash (5)—Official Final Action**

Ignite residue from total solids detn, 16.169, at temp.  $\leq 550^\circ$  until ash is C-free. Correct result for diln.

**16.171 Lead—Official First Action**

See 25.068–25.082.

**16.172 Fat (39)—Official Final Action**

(FAO/WHO method. See *Introduction*, 16.059.)

Weigh, to nearest mg, 4–5 g undild sample, 16.167(a), into fat-extn flask or tube; dil. with ca 7 mL  $\text{H}_2\text{O}$  to ca 10.5 mL and shake with slight warming (40–50°) until sample is completely dispersed. Proceed as in 16.059, beginning "Add 1.25 mL  $\text{NH}_4\text{OH}$  . . ." Some evapd milks may require centrfg as long as 20 min at 600 rpm for complete sepn of emulsion. Difference between duplicate detns obtained simultaneously by same analyst should be  $\leq 0.05$  g fat/100 g product.

**16.173 Total Nitrogen—Official Final Action**

Weigh 5 g undild sample, 16.167(a), transfer to Kjeldahl flask, and proceed as in 2.057.

% N  $\times 6.38$  = % "protein."

**16.174 Casein—Official Final Action**

Weigh 10 g dild sample, 16.167(b), into beaker, and proceed as in 16.047 or 16.049. Correct result for diln.

★ Surplus method—see inside front cover.

**16.175 Albumin—Official Final Action**

Proceed as in 16.050, using filtrate from casein detn, 16.174. Correct result for diln.

**16.176 Lactose—Official Final Action**

Proceed as in 16.056 or 16.057, using dild sample, 16.167(b), and correct result for diln.

**16.177 Gelatin—Official Final Action**

**SWEETENED CONDENSED MILK****16.180 Sampling—Official Final Action**

See 16.001–16.005 and 16.008–16.009.

**16.181 Preparation of Sample—Procedure**

(a) Temper unopened can in H<sub>2</sub>O bath at 30–35° until warm. Open, scrape out all milk adhering to interior of can, transfer to dish large enough to permit stirring thoroly, and mix until whole mass is homogeneous.

(b) Weigh 100 g thoroly mixed sample into 500 mL vol. flask, dil. to vol. with H<sub>2</sub>O, and mix thoroly. If sample will not emulsify uniformly, weigh out sep. portion of (a) for each detn.

**16.182 Lactic Acid—Official Final Action**

See 16.027–16.031.

**16.183 Total Solids—Official Final Action**

Transfer 10 mL prepd soln, 16.181(b), to weighed flat-bottom dish, ≥5 cm diam, contg 15–20 g previously dried sand or asbestos fiber. (Caution: See 51.086.) Heat on steam bath 30 min and then in vac. oven at 100° to const wt. Cool in desiccator and weigh quickly to avoid absorption of H<sub>2</sub>O. Correct result for diln.

**16.184 Ash—Official Final Action**

Evap. 10 mL prepd soln, 16.181(b), to dryness on H<sub>2</sub>O bath and ignite residue as in 31.012 or 31.013. Correct result for diln.

**16.185 Fat (39)—Official Final Action**

(FAO/WHO method. See Introduction, 16.059.)

Accurately weigh 2–2.5 g prepd sample, 16.181(a), into fat-extn flask or tube; dil. with H<sub>2</sub>O to ca 10.5 mL, and proceed as in 16.172.

**16.186 Protein—Official Final Action**

Det. N as in 2.057, using 10 mL prepd soln, 16.181(b), and correct result for diln.

% N × 6.38 = % total "protein."

**16.187 Lactose—Official Final Action**

Dil. 100 mL prepd soln, 16.181(b), in 250 mL vol. flask to ca 200 mL; add 6 mL CuSO<sub>4</sub> soln, 31.034(a), and alkali soln of concn

and in proportion as in 16.057. Dil. to vol. and mix thoroly. Filter thru dry filter and det. lactose as in 31.038. Correct result for diln.

**Sucrose—Official Final Action****16.188****Reagent**

(Caution: See 51.079 and 51.084.)

*Mercuric nitrate soln.*—To 220 g yellow HgO, add 300–400 mL H<sub>2</sub>O and enough (but with min. excess) HNO<sub>3</sub> to form clear soln (ca 140 mL), being careful to use least possible excess of acid. Dil. to 800–900 mL and slowly add 10% NaOH soln with const shaking until slight permanent ppt forms. Dil. to 1 L and filter. As soln tends to become acid with age owing to deposition of basic Hg salts, add dil. alkali occasionally until slight permanent ppt forms, and refilter.

**16.189****Determination**

Place 50 mL prepd soln, 16.181(b), in 100 mL vol. flask; add 25 mL H<sub>2</sub>O, mix, add 5 mL Hg(NO<sub>3</sub>)<sub>2</sub> soln, and shake thoroly. Without delay and with const shaking, neutze to litmus paper with 0.5N NaOH, but avoid alk. reaction (12–13 mL). Dil. to 100 mL with H<sub>2</sub>O, mix thoroly, and filter thru dry paper. Polarize filtrate in 200 mm tube; then invert at room temp. as in 31.026(c) and polarize inverted soln. Correct both readings for vol. occupied by protein, 16.186, and fat, 16.185; 1 g protein occupies 0.8 mL and 1 g fat, 1.075 mL. Calc. % sucrose by following formula, using corrected direct and invert readings obtained above:

$$S = [100(a - b)/(142.35 - (t/2))] \times (26/W),$$

where  $S$  = % sucrose in sample;  $a$  = corrected direct polarization;  $b$  = corrected invert polarization;  $t$  = temp. of soln polarized; and  $W$  = wt sample taken (10 g).

**DRIED MILK, NONFAT DRY MILK, AND MALTED MILK****16.190 Sampling Dried Milk (40)—Procedure**

(See also 16.001–16.005 and 16.010–16.011.)

Avoid sampling on rainy day or when humidity is high, so as to reduce moisture absorption from air to min.

On surface of milk at top of barrel locate point on each end of a diam. and on radius perpendicular to this diam., 2.5–5 cm (1–2") in from edge of barrel. Midway on each side of triangle between these points locate one point. At 6 points so located, using tubular trier long enough to extend full length of barrel, draw core parallel to vertical axis of barrel. Transfer cores to clean, dry, air-tight container and seal immediately.

Before opening sample for analysis, make homogeneous either by shaking or by alternately rolling and inverting container. Avoid excessive temp. and humidity when opening sample container.

**16.191 Preparation of Sample—Procedure**

Avoid absorption of moisture during prepn of sample. Mix sample by transferring to dry, air-tight container with capacity ca twice vol. of sample. Carefully mix by shaking and inverting repeatedly. When sampling, operate as rapidly as possible. If lumps are present, sift sample thru No. 20 sieve, rubbing material thru sieve and tapping vigorously, if necessary.

**16.192 Moisture (41)—Official Final Action**

Weigh 1–1.5 sample into round, flat-bottom metal dish (≥5 cm diam. and provided with tight-fitting slip-in cover). Loosen

cover and place dish on metal shelf (dish resting directly on shelf) in vac. oven at 100°. Dry to const wt (ca 5 hr) under pressure  $\leq 100$  mm (4") of Hg. During drying, admit slow current of air into oven (ca 2 bubbles/sec), dried by passing thru  $\text{H}_2\text{SO}_4$ . Stop vac. pump and carefully admit dried air into oven. Press cover tightly into dish, remove from oven, cool, and weigh. Calc. % loss in wt as moisture.

#### Protein—Official Final Action

##### 16.193 Kjeldahl Method

Weigh 1 g sample into Kjeldahl digestion flask and det. N as in 2.057.

% N  $\times 6.38$  = % "protein."

##### 16.194 Dye Binding Method

See 16.037–16.045.

##### 16.195 Casein in Malted Milk and Chocolate Malted Milk (42)—Official Final Action

Place 10 g sample in 250 mL (or larger) centr. bottle and ext with two 100 mL portions pet ether by shaking until uniform, centrfg. and decanting. To dry residue add exactly 200 mL 3%  $\text{Na}_2\text{C}_2\text{O}_4$  soln. Shake occasionally over 4 hr period. Centr. 15 min at high speed (1800 rpm if Size 1 type SB centr. is used). Pipet 50 mL supernate (100 mL for chocolate malted milk product) into 250 mL beaker. Add 50 mL paper pulp suspension (1 filter paper) and 2 mL HOAc dropwise with const stirring. Set beaker in 45–50°  $\text{H}_2\text{O}$  15 min. Cool to room temp. and filter with moderate suction thru 7 cm buchner, previously fitted with S&S 589 white ribbon paper, or equiv., and overlaid with layer of paper pulp. Wash ppt 2 or 3 times with cold  $\text{H}_2\text{O}$ . (Filtrate should be clear, or nearly so. If first portions of filtrate are not clear, repeat filtration and finish washing ppt.) Det. N in washed ppt and filter paper as in 2.057, and multiply by 6.38 to obtain equiv. casein. Correct result for blank on reagents and paper pulp.

##### 16.196 Ash—Official Final Action

Ignite 1 g sample at  $\leq 550^\circ$  until C-free. If suitable dish was used for moisture detn, 16.192, ash may be detd on same portion. Cool in desiccator and weigh.

##### 16.197 Alkalinity of Ash in Dry Skim Milk (43) Official Final Action

Ash 2 g dry skim milk 1 hr at  $\leq 550^\circ$ . Add few mL  $\text{H}_2\text{O}$  to ash, break up with flat-end stirring rod, evap. to dryness over steam bath, again ash 1 hr, and weigh. Again add few mL  $\text{H}_2\text{O}$  to ash, break up, and transfer to beaker with 50–75 mL  $\text{H}_2\text{O}$ . Add 50 mL 0.1N HCl, heat to boiling, and boil gently 5 min. Cool, add 30 mL 40%  $\text{CaCl}_2$  soln (neutrd with 0.1N HCl and filtered) and ca 10 drops phthln, and titr. excess acid with 0.1N NaOH.

Acid used (mL)  $\times 50$  = alkyl of ash.

##### 16.198 Fat in Malted Milk (44)—Official Final Action

Quickly weigh ca 1 g well mixed sample into small, lipped beaker. Add 1 mL  $\text{H}_2\text{O}$  and rub to smooth paste. Add 10 mL more of  $\text{H}_2\text{O}$ , warm on steam bath, and transfer to fat-extn flask or tube with 10 mL alcohol. Mix thoroly, cool, and proceed as in 16.059, beginning "Add 25 mL ether . . .", rinsing beaker with this ether.

#### Fat in Dried Milk (45)—Official Final Action

(FAO/WHO method. See Introduction, 16.059.)

##### 16.199

##### Preparation of Solution

Proceed as in one of following methods:

(a) Quickly weigh to nearest mg ca 1 g well mixed sample into small beaker. Add 1 mL  $\text{H}_2\text{O}$  and rub to smooth paste. Add 9 mL addnl  $\text{H}_2\text{O}$  and 1–1.25 mL  $\text{NH}_4\text{OH}$ , and warm on steam bath. Transfer to fat-extn flask or tube. Cool, and proceed as in 16.200, rinsing beaker successively with the alcohol and ethers used in first extn.

(b) Quickly weigh to nearest mg ca 1 g well mixed sample and transfer to fat-extn flask or tube. Add 10 mL  $\text{H}_2\text{O}$  and shake until homogeneous, warming if necessary. Add 1–1.25 mL  $\text{NH}_4\text{OH}$  and heat in  $\text{H}_2\text{O}$  bath 15 min at 60–70°, shaking occasionally. Cool, and proceed as in 16.200.

##### 16.200

##### Determination

Add 10 mL alcohol to sample and mix. Ext with ether and pet ether as in 16.059. For second extn add 4 mL alcohol, and again ext as in 16.059. With whole milk and cream powders make third extn, using 15 mL of each solv. after adding, if necessary, enough  $\text{H}_2\text{O}$  to bring aq. layer in tube to original vol.

Difference between duplicate detns obtained simultaneously by same analyst should be  $\leq 0.2$  g fat/100 g product.

##### 16.201 Citric Acid in Dried Milk (3) Official Final Action

Weigh 6 g well mixed sample, mix well with 44 mL  $\text{H}_2\text{O}$ , and proceed as in 16.024, beginning "... add ca 100 mg tartaric acid ..."

##### 16.202 Lactic Acid (4)—Official Final Action

See 16.027–16.031.

#### BUTTER

(Methods are also applicable to renovated or process butter and margarine)

##### 16.203 Sampling (46)—Procedure

(See also 16.001–16.005 and 16.012–16.014.)

(a) *Tub or cube butter.*—Sample lots as follows:

(1) *Tubs (or cubes) marked with churn numbers.*—Sample 1 tub of each churn of 1–9 tubs, 2 of each churn of 10–14 tubs, and 3 of each churn of >14 tubs. In no case sample <2 tubs in lot.

(2) *Tubs (or cubes) not marked with churn numbers.*—Sample number of tubs equiv. to sq root of number in lot, with min. of 3 and max. of 25. If sq root is not whole number, sample 1 extra tub.

(b) *Print butter.*—Withdraw 1 print from each of number of cases equiv. to sq root of number of cases in lot, with min. of 5 and max. of 25. When sq root is not whole number, sample 1 extra case. Select cases to include each churn or batch mark when so marked. With <5 cases, sample all, taking 5 prints as min. Remove wrapper and transfer each print to sep. sample container.

These directions provide min. sampling, to be increased if object of examination demands.

**Preparation of Sample (47)****16.204 Shaking Method—Official Final Action**

Soften entire sample in sample container, **16.014**, by warming in H<sub>2</sub>O bath kept at as low temp. as practicable,  $\leq 39^\circ$ . Avoid overheating, which causes visible sepn of curd. Shake frequently during softening process to reincorporate any sepd fat, and observe fluidity of sample. Optimum consistency is attained when emulsion is still intact but fluid enough to reveal sample level almost immediately. Remove from bath and frequently shake vigorously or place sample container in mech. shaking machine that simulates hand shaking, with arm 23 cm (9") long, set to oscillate at  $425 \pm 25$  times/min thru arc of 4.5 cm (1.75"). Continue shaking until sample cools to thick, creamy consistency and sample level can no longer readily be seen. Promptly weigh portion for analysis.

**16.205 Moisture—Official Final Action**

(FAO/WHO method. See *Introduction*, **16.059**.)

Weigh 1.5–2.5 g prepd sample of salted butter or 2–6 g unsalted butter, **16.204**, into weighed flat-bottom dish  $\geq 5$  cm diam. and dry to const wt in oven kept at temp. of boiling H<sub>2</sub>O. Clean, dry sand may be used if fat is not to be detd in residue by **16.206**.

**Fat (47)—Official Final Action****16.206 Indirect Method**

(FAO/WHO method. See *Introduction*, **16.059**.)

Take up dry butter obtained in moisture detn in which no absorbent was used, **16.205**, by macerating with 15 mL absolute ether or pet ether; transfer to weighed gooch or fritted glass crucible (16–40  $\mu$ m) with aid of wash bottle filled with the solv.; and wash free from fat with 100 mL solv. (Pass last 25 mL solv. thru crucible without suction.) Dry crucible and contents at  $100^\circ$  to const wt. Repeat washing with 25 mL solv. and dry to const wt. Repeat operation until there is no loss in wt due to washing.

% Fat =  $100 - (\% \text{ moisture} + \% \text{ residue})$ .

**16.207 Direct Method**

From dry butter obtained in detn of moisture either with or without use of absorbent, ext fat with anhyd., alcohol-free ether or pet ether (bp  $< 65^\circ$ ), receiving soln in weighed flask. Evap. solv. and dry ext to const wt at  $100^\circ$ .

**16.208 Casein, Ash, and Salt—Official Final Action**

Cover crucible contg residue from fat detn by indirect method, **16.206**; heat, gently at first, and gradually raise temp. to  $\leq 500^\circ$ . Remove cover and continue heating until residue is white. Loss in wt represents casein; residue in crucible represents mineral matter. Dissolve residue in H<sub>2</sub>O slightly acidified with HNO<sub>3</sub> and det. Cl, either gravimetrically as in **3.072**, or volumetrically as in **3.074**, and calc. % NaCl.

**16.209 Salt (48)—Official Final Action**

(FAO/WHO method. See *Introduction*, **16.059**.)

Accurately weigh ( $\pm 10$  mg) ca 5 g sample into 250 mL erlenmeyer and add 100 mL boiling H<sub>2</sub>O. Let stand, swirling occasionally, 5–10 min while cooling to  $50$ – $55^\circ$ . Add 2 mL K<sub>2</sub>CrO<sub>4</sub> indicator, **50.028(b)**, and titr. with 0.1N AgNO<sub>3</sub>, stdzd as in **50.029**, until orange-brown color persists 30 sec.

mL 0.1N AgNO<sub>3</sub>  $\times 0.585/\text{g sample} = \% \text{ NaCl}$ .

**16.210 Examination of Fat—Official Final Action**

Melt butter and keep 2–3 hr in dry place at ca  $60^\circ$ , or until H<sub>2</sub>O and curd sep. completely. Filter clear supernatant fat thru dry paper in hot H<sub>2</sub>O funnel or in oven at ca  $60^\circ$ . If filtered liq. fat is not perfectly clear, refilter. Det. physical and chem. constns as in Chap. **28**, particularly mole per cent butyric acid, **28.038–28.043**, cholesterol and phytosterol in mixts of animal and vegetable fats, **28.085–28.087**, **28.089–28.098**, and sol. and insol. volatile acids (Reichert-Meissl and Polenske values), **28.036–28.037**.

**Acid Value of Fat (49)—Official Final Action**

(Prepd by joint committee of International Dairy Federation, International Organization for Standardization, and AOAC for publication by each organization and published as an international standard in *FAO/WHO Code of Principles Concerning Milk and Milk Products and Associated Standards*.)

**16.211 Definition and Principle**

Acid value of fat from butter = mg KOH required to neutze 1 g fat. Fat sepd by melting butter, is dissolved in alcohol-ether mixt., and titrd with std alkali.

**16.212 Reagents**

(a) *Alcoholic potassium hydroxide std soln.*—0.1N. Use absolute alcohol or alcohol denatured with MeOH.

(b) *Alcohol-ether mixture.*—Equal vols alcohol (or alcohol denatured with MeOH) and ether. Add 0.3 mL phthln soln, (c)/100 mL mixt., and add alc. KOH soln, (a), to faint pink.

(c) *Phenolphthalein soln.*—1% in alcohol or alcohol denatured with MeOH.

**16.213 Determination**

Weigh, to nearest mg, 5–10 g well mixed sample, **16.210**, into 250–300 mL erlenmeyer. Add 50–100 mL alcohol-ether mixt. and 0.1 mL phthln soln. Titr. with 0.1N alc. KOH until permanent faint pink appears and persists for  $\geq 10$  sec.

Acid value = mL alc. KOH soln  $\times$  normality alc. KOH soln  $\times 56.1/\text{g sample}$ . Difference between duplicate detns should be  $\leq 0.1$  mg KOH/g fat.

**16.214 Refractive Index of Fat (49)  
Official Final Action**

(See *Introduction*, **16.211**.)

Prep. sample as in **16.210** and proceed as in **28.006**, adjusting circulating H<sub>2</sub>O to  $40 \pm 0.1^\circ$ . Correct observed refractive index by adding 0.000045 for each unit of acid value if latter is  $\geq 2$  as detd in **16.213**, rounding off to fourth decimal.

Difference between duplicate detns should be  $\leq 0.0002$ .

**Critical Temperature of Dissolution (50)  
Official Final Action****16.215 Reagent**

*Alcohol-isoamyl alcohol reagent.*—Mix 2 vols 95% (by vol.) alcohol (checked by sp gr) with 1 vol. redistd isoamyl alcohol (bp  $128$ – $132^\circ$ ), both measured with pipet or vol. flask. Keep well-stoppered.

**16.216 Apparatus**

(a) *Test tubes.*—Pyrex,  $18 \times 150$  mm, marked at 2 and 4 mL, measured by adding H<sub>2</sub>O from buret.

(b) *Micro burner.*

(c) *Pipet*.—Glass tube, ca 2–3 mL capacity, drawn to fast-flowing tip.

(d) *Thermometer*.—Range 0–100°, graduated in degrees.

#### 16.217

#### Determination

Prep. oil from butter or margarine as in 16.210. Oil must be clear. Fill test tube to 2 mL mark with oil, using pipet. Immediately add alcohol reagent to 4 mL mark (or add 2 mL with pipet). Using thermometer as stirring rod, mix the 2 layers and heat in flame of micro burner. Keep stirring and heating until mixt. becomes clear and homogeneous. *Do not boil*. Remove from heat and keep stirring until definite turbidity appears in *mixture proper*. Record temp. at first discernible turbidity. (Opalescence will immediately follow thruout entire mixt. with further drop in temp.)

#### 16.218 Color Additives—Official Final Action

Pour ca 2 g filtered fat, dissolved in ether, into each of 2 test tubes. To one tube add 1–2 mL HCl (1+1) and to other ca same vol. 10% NaOH soln. Shake tubes well and let stand. In presence of some azo dyes, acid soln turns pink to wine-red, white alk. soln in other tube shows no color. If, on other hand, annatto or other vegetable color is present, alk. soln is yellow, while no color is apparent in acid soln. (Red changing to yellow, especially on warming, in alk. soln may be due to presence of gallate antioxidants.)

*General test*.—Proceed as in Chap. 34 for detection of oil-sol. synthetic dyes and as in 16.113 for annatto.

#### 16.219 Lactic Acid—Official Final Action

See 16.027–16.031.

#### Water-Insoluble Fatty Acids (WIA)

#### 16.220 Gravimetric Method (36)—Official Final Action

(Caution: See 51.011, 51.039, and 51.054.)

Weigh 50 g prepd sample, 16.204, into 250 mL centr. bottle, and add 10 mL H<sub>2</sub>O; if necessary, remelt in warm H<sub>2</sub>O (not steam) bath and add 50 mL ether. Shake until fat dissolves.

Add 1*N* NaOH in ca 0.2 mL increments to mixt. in centr. bottle until neutzd to decided pink, using 10 drops phthln, and shaking between addns of alkali. Then add 0.5 mL excess and shake again ≥2 min. During this and all subsequent shakings, carefully release pressure several times to avoid blowing out stopper and losing some of contents. (It is difficult to shake >1 bottle at a time because of greasy stoppers and pressure that develops.)

Remove stopper and add 50 mL pet ether, shake few times, and centr. 5 min at ca 1200 rpm (longer if sepn is not sharp). Set bottle on horizontal surface and siphon off ether-fat layer. (If ether layer, after centrfg, is reddish, add 10 mL H<sub>2</sub>O, shake, and again centr. as before. If reddish tinge still persists in ether layer, add 25 mL ether, shake, and again centr.) Wash aq. layer remaining in centr. bottle by adding 25 mL ether; mix thoroly by shaking several sec, add 25 mL pet ether, and again mix by shaking. Centr., siphon off ether layer as before, and repeat washing as above. If after any washing, basic red of phthln fades, add addnl phthln and alkali to give decided red (not pink).

Add 1 mL H<sub>2</sub>SO<sub>4</sub> (1+1) to residue in centr. bottle and shake vigorously few sec. Then add 5 mL 10% Na<sub>2</sub>WO<sub>4</sub>·2H<sub>2</sub>O soln and again shake vigorously few sec. (Mixt. should be distinctly acid to *Congo red paper*; if it is not, add more H<sub>2</sub>SO<sub>4</sub>.) Now add 75 mL ether, shake violently ≥2 min, and centr. Siphon off ether layer into 500 mL separator. Wash siphon inside and out with 75 mL ether so that washings drain into centr. bottle. Shake

bottle violently ≥2 min, centr., and siphon off ether layer into the separator. (Disregard slight opalescence of ether layer.)

Add 100 mL alcohol (1+1) to combined exts in separator and neutze in same manner as before with 1*N* NaOH to decided pink. Add 0.5 mL excess and shake vigorously 2 min more. Immediately add 25 mL H<sub>2</sub>O, mix by single inversion of separator, and let stand until aq. layer is clear. (Sepn usually occurs in few min; slow sepn may sometimes be hastened by playing fine stream of H<sub>2</sub>O on ether surface. If vol. of emulsion at interface is only ca 10 mL it may be included in subsequent extrn.) Drain aq. layer into 600 mL beaker. Add 50 mL alcohol (1+1) and ca 10 drops phthln to separator and neutze with 1*N* alkali, shaking vigorously ca 2 min. Add 50 mL H<sub>2</sub>O, mix by single inversion of separator, and let stand until aq. layer is clear. Drain aq. layer into the beaker. Then add 10 mL H<sub>2</sub>O to separator, mix by single inversion, let sep. until aq. layer is clear, and drain into beaker.

Place beaker contg combined exts and washings on steam bath (or carefully heat on hot plate) to expel any ether. Evap. to ca 25 mL (small fan is useful if foaming is serious). (Soln should remain decided red thru all these operations and up to point where soaps are acidified.) Transfer to 250 mL beaker with ca 25 mL H<sub>2</sub>O. (As alternative, material may be evapd to dryness on steam bath and residue dissolved in ca 50 mL H<sub>2</sub>O.)

Dissolve 5 g anhyd. Na<sub>2</sub>SO<sub>4</sub> in warm soln (vol. must be ≥50 mL when Na<sub>2</sub>SO<sub>4</sub> and H<sub>2</sub>SO<sub>4</sub> are added), heating if necessary. Cool to ≤20°, stirring frequently to keep soaps from forming hard crust on surface. Make acid by adding H<sub>2</sub>SO<sub>4</sub> (1+1) dropwise, using Congo red paper as indicator. Stir vigorously to effect thoro liberation of fatty acids, mashing all pink soap curds. Add ca 500 mg filter-aid and mix. Filter with suction on suitable filter crucible. Rinse beaker with three ca 15 mL portions H<sub>2</sub>O at ≤20° and transfer rinsings to crucible. Maintain suction *several min after visible dripping ceases* to dry ppt. (Heavy ppts can be sucked drier if cracks are plastered up with some of ppt. Filtrate should be clear.)

Substitute tared beaker or flask (weighed with similar vessel as counterpoise), contg few glass beads or grains of sand, for receiving flask of filtering app. Ext acids with four ca 15 mL portions ether, breaking up ppt with stirring rod between extns and thoroly mixing with the ether. Let ether drip thru filter before applying suction. (Filter pad must not be disturbed.) Evap. ether ext, which should be no more than faintly opalescent, on steam bath, and dry acids 1 hr in 100° oven. Cool and weigh. Report results as mg H<sub>2</sub>O-insol. acids (WIA)/100 g butterfat.

Dissolve weighed acids in 10 mL neut. benzene and titr. with 0.1*N* Na ethylate (prepd similarly to 0.05*N* Na ethylate, 17.035(b)), using 10 drops phthln as indicator, until end point holds ≥1 min. (Neut. alcohol instead of benzene and 0.1*N* NaOH instead of Na ethylate may be used.) Compute mean mol. wt of fatty acids by dividing mg acids found by mL 0.1*N* alkali used for titrn and multiplying by 10. (Mean mol. wt should be ≤290. When amt acids is <150 mg/100 g butterfat, mean mol. wt is without significance.)

*Notes:* To siphon off ether, use tube similar to delivery tube of ordinary wash bottle but with intake end bent up into U shape in opposite direction to outlet end, with opening 6–12 mm higher than bottom of U, cut off horizontally. (Avoid excessive constriction when bending.) Set delivery tube loosely enough in stopper that it can be raised or lowered. In operating, adjust opening of U bend to ca 3 mm above surface of aq. layer and blow ether layer off by gently blowing thru mouthpiece tube inserted in adjacent hole in stopper.

Following setup is convenient for filtration of fatty acids: Bell jar and gooch with removable bottom charged with thin layer of asbestos overlaid with small amt of filter-aid (flux calcined diatomite "Speedex," Dicalite Div., Grefco, Inc., 3435 W Lomita Blvd, Torrance, CA 90505, added as suspension in H<sub>2</sub>O). Use long fiber, amphibole variety, acid and alkali-washed asbestos

for gooch, washed twice by decantation. (Coarse fritted glass crucibles overlaid with small amt of filter-aid are also satisfactory.)

### Water-Insoluble Fatty Acids (WIA) and Butyric Acid

#### Chromatographic Method—Official Final Action

16.221

#### Apparatus

*Chromatographic tube.*—Approx.  $2 \times 40$ –50 cm. Tube described in 28.038 is also satisfactory.

16.222

#### Reagents

(a) *n*-Hexane-butanol soln.—*n*-Hexane contg 1% *n*-BuOH. See 28.039(d).

(b) *Silicic acid.*—Mallinckrodt's powder especially prepd for chromatgy. Dry 2 hr at 130° and keep in tightly stoppered bottles.

(c) *Ammoniacal glycol soln.*—Dissolve 500 mg bromocresol green in 500 mL ethylene glycol by warming on steam bath. Cool, add  $\text{NH}_4\text{OH}$  dropwise until soln is dark blue (1–3 drops), and then add 1 drop excess. This soln should turn olive-green when mixed with the silicic acid.

(d) *Alcoholic potassium hydroxide std soln.*—0.05*N*. Dissolve 4 g KOH pellets in 100 mL isopropanol by warming and swirling on steam bath. Decant supernate from small amt of aq. KOH soln clinging to flask. Dil. to 1 L with 400 mL isopropanol and 500 mL alcohol. Stdze with NBS benzoic acid (SRM 350), using 2 drops thymol blue as indicator.

(e) *Thymol blue soln.*—Dissolve 300 mg thymol blue in 10 mL 0.05*N* alc. KOH and add 90 mL isopropanol. Soln should be blue; if not, add enough 0.05*N* alc. KOH to make soln dark blue.

(f) *Cresol red indicator.*—Dissolve 50 mg *o*-cresolsulfonphthalein in 20 mL alcohol. Add 1.3 mL 0.1*N* NaOH and dil. to 50 mL with  $\text{H}_2\text{O}$ .

16.223

#### Preparation of Sample

(Caution: See 51.011, 51.039, 51.054, and 51.073.)

Weigh 100 g prepd sample, 16.204, into 250 mL beaker. Melt on steam bath and transfer to 500 mL separator. Rinse beaker with 20 mL  $\text{H}_2\text{O}$  and then with 100 mL ether, and add rinsings to separator. Shake until fat dissolves.

Add 1*N* NaOH in ca 0.2 mL increments to mixt. in separator until neutzd to decided pink, using 10 drops phthln as indicator and shaking between addns of alkali. Then add 0.5 mL excess and shake again  $\geq 2$  min. Add 100 mL pet ether, shake few times, and let layers sep. (5–10 min). Drain aq. layer and any emulsion into 250 mL centrf. bottle. Shake fat layer with 10 mL  $\text{H}_2\text{O}$  and add aq. layer to centrf. bottle after sepn. Wash soln in centrf. bottle by adding 50 mL ether, mixing thoroly by shaking; add 50 mL pet ether and again mix by shaking. Centrf. 5 min at ca 1200 rpm and siphon off ether-fat layer. If sepn have not been sharp and if much fat is still present, repeat washing with 50 mL ether and 50 mL pet ether. Continue as in 16.220, beginning, 4th par., "Add 1 mL  $\text{H}_2\text{SO}_4$  (1+1) . . .", except use 10 mL 10%  $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$  instead of 5 mL and two 100 mL portions ether instead of 75 mL. When material has evapd to 25 mL on hot plate or steam bath, transfer to 100 mL beaker and evap. to dryness on steam bath or, with extreme care, on hot plate.

16.224

#### Preparation of Chromatographic Column

To 20.0 g silicic acid in mortar add 14 mL ammoniacal glycol soln. Mix thoroly with pestle until homogeneous. Add few mL hexane-BuOH soln and mix to form smooth paste; then add enough solv. to form slurry. Add slurry with spoon thru funnel to chromatgc tube contg small, loosely-packed cotton plug in

constricted end, and ca 30 mL hexane-BuOH soln. Force excess solv. thru column, using pressure of 5–10 psi (34.5–69 kPa), 18.050(c). Remove pressure when all of solv. has passed into gel but before column "cracks." Keep small amt of solv. on top of column until ready for use. Do not use cracked column.

16.225

#### Separation of Fatty Acids

To dry residue of Na salts in 100 mL beaker, 16.223, add 0.50 mL  $\text{H}_2\text{O}$  and mix well. Add 0.50 mL  $\text{H}_2\text{SO}_4$  (1+1) and mix well, being careful to break up and neutze all lumps. (Sharp needle or stirring rod is sometimes needed to scrape material from bottom of beaker.) Add 2.0 g silicic acid and stir to uniform powder.

Add enough solv. to top of column to make 5 mL. Dry sides of tube by stream of air from glass tube and rubber bulb. Transfer powder to liq. in tube. Mix powder and solv. on top of column with long stirring rod. Do not disturb surface of original gel. Force excess solv. into column with pressure. Rinse stirring rod, funnel, beaker, and sides of tube with two 10 mL portions solv., forcing excess solv. into column after each addn.

Fill tube with solv. and force solv. thru column dropwise (2–3 mL/min) with as much pressure as necessary. If column cracks or solv. flows thru column too rapidly, prep. new column, reducing amt of ammoniacal glycol soln added to silicic acid (use ca 1 mL less). If solv. flows too slowly even with pressure, use more ammoniacal glycol soln.

Collect first 125 mL eluate and titr. with std 0.05*N* alc. KOH, using 10 drops thymol blue soln as indicator. 1 mL 0.05*N* KOH = 13.5 mg WIA. Discard next 40–60 mL or until yellow band of butyric acid starts to elute. Collect next 75 mL eluate and titr. with 0.01*N* NaOH, using 25 mL  $\text{CO}_2$ -free, neutzd  $\text{H}_2\text{O}$  and 2–3 drops cresol red indicator. 1 mL 0.01*N* NaOH = 0.88 mg butyric acid. Calc. WIA and butyric acid to mg/100 g fat.

#### 16.226 ★ Rapid Method (51)—Official Final Action ★

(Does not recover salts of WIA produced by neutzn)

Butterfat sepd from cream or butter is dissolved in ether and titrd with NaOEt, using phthln. See 16.208–16.210, 12th ed.

#### 16.227 Volatile Acids—Official Final Action

Weigh 50 g sample into each of 2 centrf. bottles and proceed as in 16.220, beginning "Add 1*N* NaOH . . ." and continuing thru second washing with mixed ethers to remove fat. Then remove residual ethers from bottles by evapn on steam bath, transfer contents of both to single 200 mL vol. flask with  $\text{H}_2\text{O}$ , and add 1 mL  $\text{H}_2\text{SO}_4$  (1+1) and 10 mL 10%  $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$  soln. Dil. to vol., mix, and filter. Transfer 150 mL filtrate to distn flask and proceed with distn, chromatgc sepn, and detn as in 18.054–18.058 or 18.059. Calc. to mg acids/100 g fat.

See 14.099–14.101 for identification of volatile acids.

#### 16.228 Preservatives—Official Final Action

See 16.110 and Chap. 20.

#### 16.229 ★ Microscopic Examination—Procedure ★

See 15.153, 10th ed.

#### 16.230 Residual Phosphatase (27)—Official Final Action

See 16.118. Take sample from beneath surface with clean knife or spatula and proceed as follows:

★ Surplus method—see inside front cover.

**Step 1.**—Weigh 1.0 g sample (preferably in duplicate) on piece of waxed paper ca 2.5 cm sq and insert paper with sample into tube. Similarly, weigh another sample and place in tube as control or blank.

**Step 2.**—Heat *blank* ca 1 min to 85–90° in beaker of boiling H<sub>2</sub>O (covered so entire tube is heated to 85–90°), and cool to room temp. From this point treat blank and test alike.

**Step 3.**—Add 10.0 mL buffer substrate prep'd as in 16.116(b), except dissolve Na<sub>2</sub>C<sub>6</sub>H<sub>5</sub>PO<sub>4</sub> in 100 mL undil'd Ba borate-hydroxide buffer made from 18 g Ba(OH)<sub>2</sub>·8H<sub>2</sub>O and 8 g H<sub>3</sub>BO<sub>3</sub>/L. Stopper tube and mix.

**Step 4.**—Immediately after adding substrate, incubate 1 hr in H<sub>2</sub>O bath at 37–38°, mixing or shaking contents occasionally.

**Step 5.**—Heat in beaker of boiling H<sub>2</sub>O nearly 1 min, heating to 85–90° (use thermometer in another tube of same size and shape contg same vol. of liq.), and cool to room temp. in vessel of cold H<sub>2</sub>O.

**Step 6.**—Pipet in 1 mL 6.0% ZnSO<sub>4</sub>·7H<sub>2</sub>O soln, and mix thoroly (pH of mixt. should be 9.0–9.1).

**Step 7.**—Filter (5 cm funnel, 9 cm Whatman No. 42 or No. 2 paper recommended), and collect 5.0 mL filtrate in tube, preferably graduated at 5.0 and 10.0 mL.

**Steps 8–11.**—Proceed as in 16.118.

**Step 12.**—When using 1.0 g butter and adding 11.0 mL liq., multiply value of reading by 1.1 to convert result to phenol eqivs/0.5 g butter. (Values >2 eqivs/0.5 g indicate underpasteurization.)

See 16.129–16.130 for differential test for reactivated and residual phosphatase.

## CHEESE

### 16.231 Collection of Sample—Procedure

(See also 16.001–16.005 and 16.015–16.018.)

When cheese can be cut, take narrow wedge reaching from outer edge to center. When not permissible to cut cheese, take sample with cheese trier. If only one plug can be obtained, take it perpendicular to surface of cheese at point 1/3 distance from edge to center and extending either entirely or half-way thru. When >1 plug can be taken, draw 3 plugs, 1 from center, 1 near outer edge, and 1 midway between other two. Use ca 2 cm (3/4") of rind portion of core to reseal hole.

Sample bulk containers of cottage and similar cheeses by stirring can thoroly for ≥5 min with dairy stirrer (ca 14 cm (5.5") perforated concave metal disk attached to ca 70 cm (27") metal rod as handle) so that all portions of container are reached. Remove portions from top surface with small spoon to fill 0.5 L (1 pt) jar, and cover.

### 16.232 Preparation of Sample—Procedure

Cut wedge sample into strips and pass 3 times thru food chopper. Grind plugs in food chopper (preferable method), or cut or shred very finely and mix thoroly.

With creamed cottage and similar cheeses, place 300–600 g sample at <15° in 1 L (1 qt) cup of high-speed blender and blend for min. time (2–5 min) required to obtain homogeneous mixt. Final temp. should be ≤25°. This may require stopping blender frequently after channeling and spooning cheese back into blades until blending action starts. (Use of variable transformer in line to permit slow speed at first minimizes channeling when speed is increased later.)

## Moisture

### 16.233 Method I (52)—Official Final Action

Weigh 2–3 g prep'd sample, 16.232, into weighed round, flat-bottom metal dish, ≥5 cm diam. and provided with tight-fit, slip-in cover. In case of soft cheese and process cheese of high moisture content, weigh 1–2 g and partially dry on steam bath. Place loosely covered dish on metal shelf (dish resting directly on shelf) in vac. oven, kept at 100°. Dry to const wt (ca 4 hr) under pressure ≤100 mm Hg (13.3 kPa). During drying admit into oven slow current of air (ca 2 bubbles/sec) dried by passing thru H<sub>2</sub>SO<sub>4</sub>. Stop vac. pump and carefully admit air into oven. Press cover tightly into dish, remove dish from oven, cool, and weigh. Express loss in wt as moisture.

### 16.234 Method II (Rapid Screening Method) (53) Official First Action

Weigh 2–3 g prep'd sample into moisture dish with tight-fit cover. Partially dry on steam bath with lid removed and then insert in forced-draft oven that has come to equilibrium at 130±1°. Dry 1.25 hr (with cover entirely off), cover tightly, remove from oven, cool, and weigh.

### Method III (Distillation Method) (54)—Official Final Action

(Applicable to blue and other cheeses contg significant amts of substances other than H<sub>2</sub>O volatile at 100°)

### 16.235

### Apparatus

(a) *Receiver.*—Bidwell & Sterling, or modified Bidwell & Sterling, with 5 mL volumetric tube 146–156 mm long, graduated in 0.05 or 0.1 mL divisions, with ♂ or ♀ joints, upper 24/40, lower 24/40 or 40/50 (SGA Scientific Inc., No. D8580 or JD7780, or equiv.).

(b) *Condenser.*—Cold-finger type, supported by smooth, uniform shoulder in uniformly and symmetrically flared glass tube connected to receiver by ♂ joint. Diam. of shoulder is 20–35 mm, and length below shoulder 75–100 mm. Powder funnel with ♂ or ♀ joint is suitable support. Flare exceeds diam. of condenser shoulder, and makes close, uniform, but never tight, fit with condenser at entire ring of contact with shoulder. Maintain ring of solv. between shoulder and support during heating-up period, while allowing expanding air in system to bubble past. Portion of condenser below shoulder should hang free, and cooling H<sub>2</sub>O entrance and exit tubes should be clear of condenser support. Lower tip should be well above the surface of solv. in receiver.

(c) *Boiling flask.*—250 mL, r-b, short neck, ♂ or ♀ 40/50 joint with, if necessary, reducing adapter, ♂ 24/40–40/50, for receivers with lower joint ♂ 24/40.

(d) *Heating mantle connected to voltage controller.*

### 16.236

### Distillation Solvent

Mix *n*-amyl alcohol and xylene, 1+2, and distil at temp. plateau, ca 129–134°. Add ≤5 mL H<sub>2</sub>O to convenient vol. of dist'd solv. mixt., distil off H<sub>2</sub>O as in stdzn of app., cool, and store solv. mixt. in g-s container. If in stdzn of app., using solv. mixt. without distg or equilibrating, no significant difference is found from value obtained with distg, these steps may be omitted. (Baker's Analyzed Reagent, or equiv., *n*-amyl alcohol and xylene have been found satisfactory as received.)

### 16.237

### Standardization of Apparatus

Support app. adequately to maintain tight connections. Lubricate lower joints with USP White Petrolatum. Sep. insulate side arm of receiver and exposed portion of flask with Fiberglass,

nonabsorbent cotton, or other suitable material. Thoroughly clean and dry interior of app., rinse with anhyd. MeOH and then with distn solv., and fill volumetric tube of receiver with solv. Likewise rinse interior portion of condenser, wipe with clean, dry wiping tissue, and immediately insert condenser in app. Dry externally exposed portion of condenser with tissue wipes, and shield as needed to prevent accumulation of condensed atm. H<sub>2</sub>O.

Add to clean, dry boiling flask enough SiC fragments, or similar sharp, nonporous boiling aids of mixed size, 6–25 mesh, mostly 10–20, to cover bottom to diam.  $\geq 4$  cm. Add ca 10 mL distn solv., and redry by distn, if necessary, at low heat. Cover flask loosely and cool; then cover flask tightly to exclude H<sub>2</sub>O and weigh to 0.001 g. Add ca 4.5 g H<sub>2</sub>O, quickly re-cover flask, and reweigh to obtain wt H<sub>2</sub>O to  $\pm 0.001$  g.

Immediately add ca 60 mL distn solv. to flask and connect to receiver. Heat slowly until refluxing starts; adjust heat to distil 20–30 min at ca 0.2–0.3 mL H<sub>2</sub>O/min; then increase rate of refluxing gradually to rate attained by full voltage. When no more H<sub>2</sub>O droplets fall from tip of condenser, lift condenser and rinse walls of receiver and that portion of condenser inside system with distn solv. from plastic squeeze-type bottle with fine tip. Continue distn few min and repeat rinsing. Repeat this operation at intervals of 1–2 min until no more H<sub>2</sub>O droplets are seen to fall into volumetric tube. Remove condenser and support it in dry, clean flask, e.g., 125 mL  $\frac{3}{4}$  24/40 erlenmeyer. Remove boiling flask, first tilting receiver slightly to return some of solv. to flask, and place on supporting ring to cool.

Immerse volumetric tube in H<sub>2</sub>O at convenient temp. (25° or room temp.) and when equilibrium is reached, read, and est. vol. distd H<sub>2</sub>O to nearest 0.01 mL. Magnifier is helpful; avoid parallax.

Calc. distn factor at temp. selected = g H<sub>2</sub>O added/mL H<sub>2</sub>O distd.

Repeat stdzn until consecutively detd factors agree within  $\pm 0.002$  of av. of 2. Use av. of the 2 detns as distn factor.

**16.238****Determination**

Prep. app. and distn solv. as in 16.237. Place in covered, dry, weighed boiling flask, contg boiling aids and ca 10 mL distn solv., portion of well mixed sample contg ca 4.5 g H<sub>2</sub>O, e.g., 9–11 g soft cheeses (camembert, etc.), 11–13 g cheddar, blue, etc. (35–40% H<sub>2</sub>O), and 13–15 g hard, dry cheeses. Immediately re-cover tightly and reweigh to  $\pm 0.005$  g.

Add ca 60 mL distn solv. and connect to app. (or, after addn of solv., samples may be held in tightly closed flasks until ready to distil). Start heating slowly and distil H<sub>2</sub>O in same manner as in 16.237, but refluxing slowly at low heat for ca 40–50 min, then increasing heat gradually to full voltage for few min, using same criteria for completion of distn. Cheese will spread in thin layer over bottom of flask and will become tan to brownish yellow, depending on variety, but not dark brown or scorched in appearance. Complete distn in 1–1.25 hr. Read vol. distd H<sub>2</sub>O under exactly same conditions as in 16.237. Calc. % H<sub>2</sub>O in sample = (distn factor  $\times$  vol. H<sub>2</sub>O distd  $\times$  100)/g sample.

Remove dried cheese from flask by digesting with dil. alkali soln on steam bath until dispersed, then washing with hot H<sub>2</sub>O, reusing washed boiling aids. Used solv. may be distd for re-use.

**Method IV (Microwave Oven Method) (55)**  
**Official First Action**

**16.239****Apparatus**

**Microwave tester.**—App. consists of microwave oven operating at 2,450 megahertz and calibrated at factory to give direct readout in % moisture (vac. oven method, 16.233) using specified

power setting and time. Available from Apollo Microwave Products, 6204 Official Rd, Crystal Lake, IL 60014. Operate in accordance with instructions from manufacturer.

**16.240****Determination**

Prep. sample as in 16.232. Place 100  $\times$  10 mm Petri dish contg 11 cm circle of glass fiber filter and Teflon ring on built-in weighing mechanism of oven and tare to zero. Evenly spread 10.00 g sample over surface of dish and cover with glass paper held in place with Teflon ring. Place dish on weighing platform within microwave cavity. Close door and set timer for 2.25 min and power for 74 units. Activate unit and when app. shuts off, read % moisture directly.

Check calibration periodically against samples analyzed by 16.233. Adjust time and power setting to maintain correspondence in values. Adjustment is necessary only when several samples consistently give values outside 2 times std deviation of difference from 16.233.

**16.241 Ash (56)—Official Final Action**

Weigh 3–5 g prepd sample, 16.232, into Pt dish, place on steam bath, and dry ca 1 hr. (If cheese is high in fat, place small amt of absorbent cotton in dish.) Ignite cautiously to avoid spattering and remove burner while fat is burning. When flame ceases, complete ignition in furnace at  $\leq 550^\circ$ , cool, and weigh.

**Total Chlorides (57)—Official Final Action****IDF-ISO-AOAC Method**

(Applicable to all cheeses contg  $\geq 0.5\%$  Cl)

**16.242****Principle**

Cheese is digested with KMnO<sub>4</sub> and HNO<sub>3</sub>, and Cl is detd by titrn with AgNO<sub>3</sub> in presence of NH<sub>4</sub>Fe(SO<sub>4</sub>)<sub>2</sub> as indicator.

**16.243****Determination**

(Caution: See 51.069.)

Accurately weigh ca 2 g prepd sample, 16.015–16.018 and 16.231–16.232, into 300 mL erlenmeyer. Pipet in 25 mL 0.1N AgNO<sub>3</sub>, 50.027–50.031, add 25 mL HNO<sub>3</sub>, and mix thoroly. Heat to boiling, add ca 10 mL satd KMnO<sub>4</sub> soln, and maintain gentle boiling. After decolorization, add addnl 5–10 mL satd KMnO<sub>4</sub> soln until brown color indicates destruction of org. matter is complete. Remove excess KMnO<sub>4</sub> by adding small amt oxalic acid or glucose. Add 100 mL cold H<sub>2</sub>O and 2 mL satd NH<sub>4</sub>Fe(SO<sub>4</sub>)<sub>2</sub> soln and mix thoroly. Immediately titr. excess AgNO<sub>3</sub> with 0.1N NH<sub>4</sub>SCN or KSCN, 50.002–50.004, until soln is red-brown 30 sec. Analyze blank, using 2 mL H<sub>2</sub>O in place of 2 g cheese.

$$\% \text{ Cl} = [(V_1 - V_2) \times f \times N] / W,$$

where  $V_1$  = mL SCN soln used for blank,  $V_2$  = mL SCN soln used for sample,  $N$  = normality of SCN soln,  $W$  = g sample, and  $f$  = 3.55 for Cl (5.85 for NaCl).

**16.244 Salt—Procedure**

See 24.011–24.014.

**16.245 Nitrogen—Official Final Action**

Det. N in weighed portion (ca 2 g) prepd sample, 16.232, as in 2.057.

$$\% \text{ N} \times 6.38 = \% \text{ "protein."}$$

**16.246 Titanium (58)—Official Final Action**

See 25.139–25.142.

**16.247 Acidity—Official Final Action**

To 10 g prepd sample, **16.232**, add H<sub>2</sub>O at 40° to vol. of 105 mL, shake vigorously, and filter. Titr. 25 mL portion filtrate, representing 2.5 g sample, with std NaOH, preferably 0.1*N*, using phthln. Express result as lactic acid. 1 mL 0.1*N* NaOH = 0.0090 g lactic acid. Results may also be expressed as mL 0.1*N* NaOH/100 g.

**16.248 Color Additives—Official First Action**

(Caution: See **51.011**, **51.039**, and **51.054**.)

Ext 25–50 g prepd sample, **16.232**, with ether, remove ether by evapn, and proceed as in Chap. **34**.

**Nitrate and Nitrite (59)—Official Final Action**

(Applicable to cheeses contg  $\geq 1$  ppm NO<sub>3</sub>)

**16.249****Apparatus and Reagents**

(a) *Modified Jones reductor*.—Glass tube, 300 × 10 mm id, with stopcock, and reservoir consisting of 200 mL addn funnel with  $\frac{1}{8}$  24/40 stopper (see Fig. **16:04**), or equiv. chromatgc column with stopcock.

(b) *Ammonia buffer soln.*—pH 9.6–9.7. Dil. 20 mL HCl to 500 mL with H<sub>2</sub>O. Mix, and add 50 mL NH<sub>4</sub>OH. Dil. to 1 L and mix. Check pH, and adjust if necessary.

(c) *Cadmium sulfate soln.*—0.14*M*. Dissolve 37 g 3CdSO<sub>4</sub>·8H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L.

(d) *Color reagent*.—Dissolve 2.10 g sulfanilic acid (Eastman Organic Chemicals, or equiv.) in 250 mL 15% (v/v) HOAc by heating on steam bath. Dissolve 0.521 g 1-naphthylamine.HCl (Caution: See **51.085**) (Eastman Organic Chemicals, or equiv.) in 30 mL H<sub>2</sub>O by heating on steam bath. Pour while still hot into 250 mL 15% HOAc. Mix the 2 solns, filter if necessary, and store in g-s brown glass bottle in refrigerator. Prep. fresh weekly.

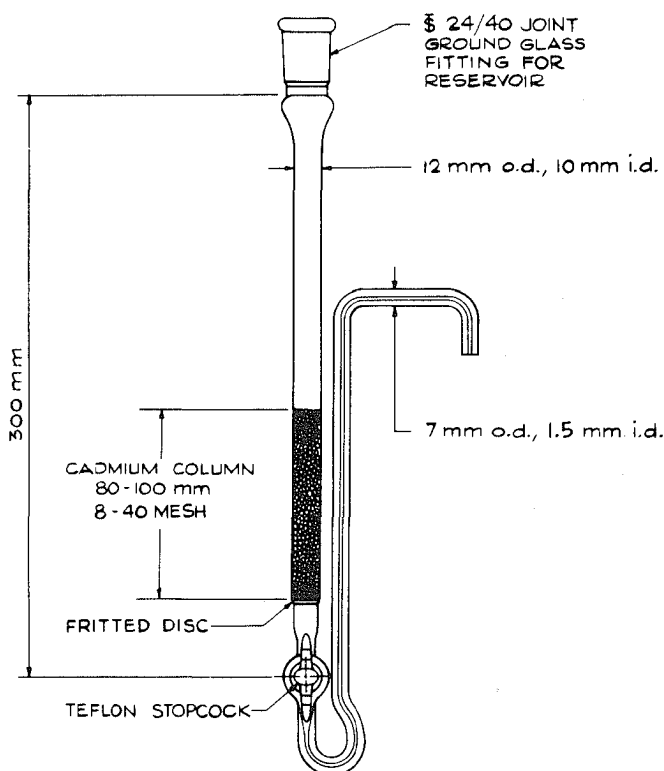

FIG. 16:04—Modified Jones reductor

(e) *Zinc*.—Approx. 10 cm sticks.

(f) *Zinc sulfate soln.*—0.42*M*. Dissolve 120 g ZnSO<sub>4</sub>·7H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L.

(g) *Potassium nitrate std solns.*—(1) *Stock soln.*—1 mg NO<sub>3</sub>/mL. Dissolve ca 1.6308 g KNO<sub>3</sub> primary std (Fisher Scientific Co., or equiv.), previously dried 1 hr at 110° and accurately weighed, in H<sub>2</sub>O, dil. to 1 L, and mix. (2) *Working soln.*—10 μg NO<sub>3</sub>/mL. Transfer 10.0 mL stock soln to 1 L vol. flask, dil. to vol. with H<sub>2</sub>O, and mix.

(h) *Sodium nitrite std solns.*—(1) *Stock soln.*—0.2 mg NO<sub>2</sub>/mL. Dissolve ca 0.3000 g NaNO<sub>2</sub> primary std (Fisher Scientific Co., or equiv.), previously dried 1 hr at 110° and accurately weighed, in H<sub>2</sub>O, dil. to 1 L, and mix. (2) *Working soln.*—2 μg NO<sub>2</sub>/mL. Transfer 10 mL stock soln to 1 L vol. flask, dil. to vol. with H<sub>2</sub>O, and mix.

**16.250****Preparation of Samples**

Remove any wax coating and outer portion of cheese rind and any surface mold.

(a) *Very hard (less than 25% moisture) and hard and semisoft (less than 40% moisture) cheeses.*—Dice into  $\leq 6$  mm cubes and mix thoroly. Grind 3 times. Some hard varieties may be grated.

(b) *Soft (more than 40% moisture) cheeses.*—Composite and mix well.

Store all cheese in glass jars with tight-fitting lids. Prep. cheese-H<sub>2</sub>O slurry (1+2) (cheese factor =  $\frac{1}{3}$ , inverse of which appears in final equation). Blend in high-speed blender at high speed until smooth.

**16.251****Extraction**

Accurately weigh ca 30 ± 0.1 g slurry into 200 mL vol. flask. Add 70 mL H<sub>2</sub>O and heat to ca 50°, swirling occasionally. Add 10 mL ZnSO<sub>4</sub> soln and 12 mL 2% NaOH soln, swirling after each addn. Maintain temp. at ca 50° for addnl 10 min, swirling occasionally. Cool to room temp. in H<sub>2</sub>O bath. Dil. to vol. with H<sub>2</sub>O and mix thoroly. Filter thru fluted paper, discarding first 20 mL filtrate, into 250 mL g-s flask. Refilter if ext is not clear. Sample exts are stable at this point. Reserve portion of this unreduced filtrate for **16.254**.

Prep. H<sub>2</sub>O reagent blank by omitting cheese slurry. Reserve blank for use in **16.253** and **16.254**.

**16.252****Preparation of Standard Curve**

Add 0, 1, 2, 3, 4, 5, 10, and 15 mL NaNO<sub>2</sub> working std soln to sep. 50 mL vol. flasks. Add 10.0 mL color reagent, dil. to vol. with H<sub>2</sub>O, mix, and let stand in dark 25 min. Read spectrophtrc in 1 cm cells at max. *A*, 522 ± 2 nm, against blank (0 std addn). Scan from 640 to 440 nm with recording spectrophtr. Prep. calibration curve by plotting *A* at max. against μg NO<sub>2</sub>/50 mL.

**16.253****Preparation of Modified Jones Reductor**

Place 3–5 Zn sticks each in 2 sep. 800 mL beakers contg 500 mL CdSO<sub>4</sub> soln. Remove Zn sticks every 2–3 hr and scrape off spongy metallic Cd by rubbing sticks against each other. After 6–8 hr, decant and wash deposits with two 500 mL portions H<sub>2</sub>O. (Caution: Cd must be kept covered with aq. soln.) Transfer Cd with H<sub>2</sub>O to high-speed blender and blend 2–3 sec. Retain 8–40 mesh particles. Repeat to increase yield of particles. Wash particles with 0.1*N* HCl, stirring occasionally with glass rod. Leave overnight in acid. Stir once more to degas. Decant and wash with two 100 mL portions H<sub>2</sub>O. Fill modified Jones reductor to depth of 8–10 cm with Cd, draining occasionally during filling but not letting liq. level fall below top of bed. Eliminate bubbles in bed by tapping sides of column.

With stopcock closed, add 10 mL  $\text{NH}_3$  buffer soln to column. Add 40 mL  $\text{KNO}_3$  working std soln to column with reservoir in place. Adjust flow rate initially to 3–5 mL/min, and do not readjust. Collect eluate in 100 mL vol. flask. Just as column empties, wash reservoir and column walls with ca 15 mL  $\text{H}_2\text{O}$ . Repeat with two 15 mL portions  $\text{H}_2\text{O}$ . After collecting nearly 100 mL eluate, remove flask and dil. to vol. with  $\text{H}_2\text{O}$ . Recondition column with 25 mL 0.1N HCl followed by two 25 mL portions  $\text{H}_2\text{O}$  and 25 mL  $\text{NH}_3$  buffer soln, and repeat process, using 40 mL  $\text{H}_2\text{O}$  reagent blank from 16.251. Mix, and add 5 mL of blank and std eluates to sep. 50 mL vol. flasks. Proceed as in 16.252, beginning "Add 10.0 mL color reagent, . . ." Read spectrophotric as in 16.252 against blank similarly treated.

If  $\text{NO}_2$  concn, as detd from calibration curve, is  $<13.4 \mu\text{g}/50 \text{ mL}$  ( $<90\%$  recovery), recondition column: Transfer Cd particles to beaker contg 2N HCl for 1 min. Decant and wash with two 100 mL portions  $\text{H}_2\text{O}$ . Proceed as in par. 1, beginning "Fill modified Jones reductor . . .".

Jones reductor may be stored under  $\text{H}_2\text{O}$  between analyses. Recondition column before each analysis with 25 mL 0.1N HCl followed by two 25 mL portions  $\text{H}_2\text{O}$  and 25 mL  $\text{NH}_3$  buffer soln.

#### 16.254

#### Determination

Proceed as in 16.253, par. 2, from beginning to ". . . remove flask and dil. to vol. with  $\text{H}_2\text{O}$ .", except add 40 mL sample filtrate from 16.251 to column instead of  $\text{KNO}_3$  std.

Add 2.0 mL unreduced sample filtrate, 2.0 mL  $\text{H}_2\text{O}$  reagent blank from 16.251, and 5.0 mL reduced eluate from 16.253 to sep. 50 mL vol. flasks, and proceed as in 16.252, beginning "Add 10.0 mL color reagent, . . .", except read unreduced sample filtrate and reduced eluate against the blank. Alter dilns, if necessary, using 1–40 mL reduced eluate and unreduced filtrate, depending upon  $\text{NO}_2$  concn of sample. Final dilns should give similar diln factors. For very high  $\text{NO}_2$  concns, prior diln with  $\text{H}_2\text{O}$  may be necessary.

$$\text{ppm NaNO}_3 = [(R - U) \times D \times 3 \times 1.3478 \times 1.371]/W \\ = [(R - U) \times D \times 5.544]/W,$$

where  $R = \mu\text{g NO}_2/50 \text{ mL}$  reduced eluate (from std curve),  $U = \mu\text{g NO}_2/50 \text{ mL}$  unreduced filtrate (from std curve),  $D = \text{diln factor}$ ,  $\frac{1}{3} = \text{cheese factor}$ , 1.3478 =  $\text{NO}_2$  to  $\text{NO}_3$  conversion factor, 1.371 =  $\text{NO}_3$  to  $\text{NaNO}_3$  conversion factor, and  $W = \text{g sample slurry}$ .

#### 16.255 Fat (60)—Official Final Action

(FAO/WHO method. See Introduction, 16.059.)

Weigh, to nearest mg, ca 1 g prepd sample, 16.232, into small tall-form beaker; add 9 mL  $\text{H}_2\text{O}$  and, if desired, 1 mL  $\text{NH}_4\text{OH}$ . Mix until smooth; then warm mixt. at low heat until casein is well softened. If  $\text{NH}_4\text{OH}$  was used, neutze with HCl, using litmus as indicator. Add 10 mL HCl and few glass beads or other inert material, previously digested with HCl, to prevent bumping, cover with watch glass, and boil gently 5 min, or place beaker in boiling  $\text{H}_2\text{O}$  bath 20 min. Cool soln; transfer to fat-extn flask or tube; rinse beaker successively with 10 mL alcohol, 25 mL ether, and 25 mL pet ether (boiling range 30–60°); transfer rinsings to flask; and mix thoroly after adding each reagent. Proceed as in 16.059, beginning "Centrf. flask . . ." Difference between duplicate detns obtained simultaneously by same analyst should be  $\leq 0.2 \text{ g fat}/100 \text{ g product}$ .

#### 16.256 Fat in Whey Cheese (61)—Official First Action

(FAO/WHO method. See Introduction, 16.059.)

Weigh, to nearest mg, ca 3 g prepd sample, 16.232, into extn

flask and add 10 mL  $\text{H}_2\text{O}$ . Disperse by gentle agitation in boiling  $\text{H}_2\text{O}$  bath and continue heating 20 min in bath. Add 2 mL  $\text{NH}_4\text{OH}$ , mix, and cool. Continue as in 16.059, beginning "Add 10 mL alcohol and mix well." Difference between duplicate detns obtained simultaneously by same analysts should be  $\leq 0.2 \text{ g fat}/100 \text{ g product}$ .

#### 16.257 Examination of Fat—Official Final Action

(a) *Alkaline extraction*.—In large, wide-mouth flask, treat ca 300 g sample, cut to ca pea-size, with 700 mL 5% KOH soln at 20°, shaking vigorously to dissolve casein. (In 5–10 min, casein dissolves, and fat rises to surface in lumps.) Collect lumps of fat into as large mass as possible by shaking gently. Pour cold  $\text{H}_2\text{O}$  into flask until fat is driven up into neck, and remove by suitable means. Wash fat thus obtained with just enough  $\text{H}_2\text{O}$  to remove residual alkali. Fat is not perceptibly attacked by alkali in this treatment, is practically all sepd in short time, and is then easily prepd for chem. analysis by filtering and drying as in 16.210. Examine fat as in Chap. 28.

(b) *Acid extraction*.—Pass cheese thru grinder, transfer to large flask, and cover with warm  $\text{H}_2\text{O}$ , using 1 mL/g cheese. Shake thoroly and add  $\text{H}_2\text{SO}_4$  slowly and in small amts, shaking after each addn of acid. (Vol.  $\text{H}_2\text{SO}_4$  should equal vol.  $\text{H}_2\text{O}$  used.) Transfer fat, which seps after standing few min, to separator; wash free from sulfate, filter, and dry as in 16.210. Examine fat as in Chap. 28.

#### Tartaric Acid (62)

#### 16.258 Qualitative Test—Procedure

To 5 g ground cheese, 16.232, add 40 mL  $\text{H}_2\text{O}$  at ca 50° and shake until cheese is thoroly broken up. Add 3 mL 1%  $\text{H}_2\text{SO}_4$  and shake vigorously. Add 2 mL 20% *phosphotungstic acid soln* and again shake vigorously. Let stand 5 min and filter. To 25 mL filtrate add enough satd  $\text{Ba}(\text{OH})_2$  soln to make alk. and 25 mL alcohol, shake vigorously, and let settle. Filter thru buchner, using light suction, and wash residue on filter several times with  $\text{H}_2\text{O}$ . Transfer portion of paste to small evapg dish and dry on steam bath. Add few mL  $\text{H}_2\text{SO}_4$  and few crystals of *resorcin*, and heat slowly. If tartaric acid is present, soln turns rose-red; color is slowly discharged on diln with  $\text{H}_2\text{O}$ .

#### Quantitative Method (62)—Official Final Action

#### 16.259

#### Reagents

(a) *Potassium chloride wash soln*.—Dissolve 15 g KCl in 100 mL  $\text{H}_2\text{O}$  and add 20 mL alcohol.

(b) *Tartaric acid soln*.—Dissolve 1.5 g pure tartaric acid in previously boiled and cooled  $\text{H}_2\text{O}$  and dil. to 100 mL at 20°. Titr. with 0.1N NaOH to det. wt tartaric acid in 10 mL soln.

(c) *Hydrochloric acid soln*.—2%. Dil. 47 mL HCl to 1 L with  $\text{H}_2\text{O}$ .

#### 16.260

#### Determination

Weigh 25 g prepd sample, 16.232, into 500 mL wide-mouth bottle and add, 25 mL at time, 100 mL  $\text{H}_2\text{O}$  at 50–60°, shaking vigorously after each addn. Continue shaking until cheese is thoroly broken up. Add 25 mL 2%  $\text{Na}_2\text{C}_2\text{O}_4$  soln and shake vigorously 1 min. Add 100 mL 2% HCl, 25 mL at time, shaking vigorously after each addn. Add 50 g powd KCl and shake 5 min. To avoid churning, keep mixt. warm (ca 50°) during shaking. Transfer mixt., with aid of  $\text{H}_2\text{O}$ , to 300 mL vol. flask, cool to 20°, and dil. to vol. with  $\text{H}_2\text{O}$ . Mix thoroly; let stand 10 min, with occasional shaking, and filter thru dry folded paper, discarding first few mL filtrate. Disregard any opalescence and transfer 200

mL filtrate to 250 mL vol. flask. Neutze with 1*N* NaOH, using phthln, and add 5.2 mL in excess. Dil. to vol. with H<sub>2</sub>O, mix thoroly, let stand few min, and filter thru dry folded paper, discarding first few mL filtrate.

To 100 mL filtrate in 250 mL beaker add, with constant stirring, 10 mL of the tartaric acid soln, 2 mL HOAc, and 23 mL alcohol. Cool in ice bath, stir vigorously until cream of tartar begins to crystallize, and let stand in refrigerator overnight. Prep. Caldwell crucible with pad of asbestos ca 10 mm thick. (*Caution: See 51.086.*) Decant most of liq. thru this filter, wash ppt into crucible with KCl wash soln, and wash beaker and ppt 3 times, using total of 20–30 mL wash soln. Place asbestos and ppt in beaker in which pptn was made and wash crucible with ca 50 mL hot H<sub>2</sub>O. Heat soln to bp and titr. while hot with 0.1*N* NaOH, using phthln. Calc. % tartaric acid in cheese by formula:

$$X = 14.26[0.015(B+1.5) - C],$$

where *C* = g tartaric acid in 10 mL of the tartaric acid reagent; and *B* = mL 0.1*N* NaOH required for titrn. In factor 14.26, concn caused by insol. solids of cheese of av. composition is taken into consideration.

### Citric Acid (63)

#### 16.261 Qualitative Test—Procedure

To 10 g prepd sample, **16.232**, add 20 mL H<sub>2</sub>O at ca 50° and shake vigorously until cheese is thoroly broken up. Add 20 mL H<sub>2</sub>SO<sub>4</sub> (1+1) and 2 mL 20% phosphotungstic acid soln, and shake vigorously. Let stand 5 min and filter. To 20 mL filtrate add 10 mL Br-H<sub>2</sub>O (*Caution: See 51.047*) and 5 mL KBr soln (15 g in 40 mL H<sub>2</sub>O), and proceed with oxidn as in **16.262**. Add enough FeSO<sub>4</sub> soln (**16.262**, par. 3) to dissolve pptd MnO<sub>2</sub>. If citric acid is present, heavy white ppt forms which settles rapidly.

#### 16.262 Quantitative Gravimetric Method Official Final Action

Prep. suspension as in **16.260** thru addn of Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln. Shake vigorously 1 min and add 100 mL 1% H<sub>2</sub>SO<sub>4</sub>, 25 mL at time, shaking vigorously after each addn. Add 3 mL 20% phosphotungstic acid soln and shake; then add 25 g powd anhyd. Na<sub>2</sub>SO<sub>4</sub>, and shake 5 min. To avoid churning, keep mixt. warm (ca 50°) during shaking. Transfer mixt. with aid of warm H<sub>2</sub>O to 300 mL vol. flask, cool to 20°, and dil. to vol. with H<sub>2</sub>O. Mix thoroly, shake occasionally during 10 min, and filter thru dry folded paper, discarding first few mL filtrate.

Heat 200 mL filtrate to bp and while still hot add 20 mL H<sub>2</sub>SO<sub>4</sub> (1+1) and 2 mL phosphotungstic acid soln. Mix, and let stand 15 min. With aid of H<sub>2</sub>O, transfer mixt. to 250 mL vol. flask, cool to 20°, dil. to vol. with H<sub>2</sub>O, and filter thru dry folded paper.

Transfer 100 mL clear filtrate to 500 mL erlenmeyer (ca 0.3 g washed and dried asbestos may be added). Add 10 mL freshly prepd satd Br-H<sub>2</sub>O (*Caution: See 51.047*) and 5 mL KBr soln (15 g KBr in 40 mL H<sub>2</sub>O), mix thoroly, and heat to 48–50°. Hold at this temp. 5 min, add 25 mL 5% KMnO<sub>4</sub> soln, shake, and let stand ca 5 min. Cool flask and contents to ca 8°, add 40 mL cold FeSO<sub>4</sub> soln (20 g FeSO<sub>4</sub>·7H<sub>2</sub>O in 100 mL H<sub>2</sub>O and 1 mL H<sub>2</sub>SO<sub>4</sub>), shake continuously 5 min, and let mixt. stand overnight in refrigerator.

Decant supernate thru gooch, measure vol. filtrate (v), and wash ppt from erlenmeyer into crucible with this filtrate. Wash ppt with three 20 mL portions ice-cold H<sub>2</sub>SO<sub>4</sub> (1+100), suck dry after each addn, and finally wash with three 20 mL portions ice-cold H<sub>2</sub>O. Dry ppt to const wt over H<sub>2</sub>SO<sub>4</sub> in vac. desiccator, protecting ppt from strong light or, to save time, dry in current of air passed thru H<sub>2</sub>SO<sub>4</sub>, and weigh.

Remove pentabromacetone by extg first with three 20 mL

portions alcohol and then with three 20 mL portions ether. Dry and weigh crucible. To wt pentabromacetone add 0.004 g/100 mL filtrate (v) to compensate for solubility of pentabromacetone and multiply result by 6.06 to obtain % anhyd. citric acid in cheese. (In this factor, concn caused by insol. solids in 25 g cheese is taken into consideration. It is assumed that solids of cheese are almost insol. under conditions maintained and that av. process cheese contains ca 60% solids. No allowance is made for variation in salt or moisture content or for variation in specific vol. of solids, as such variations do not appreciably affect results.)

#### IDF-ISO-AOAC Colorimetric Method (57) Official Final Action

#### 16.263

#### Principle

Cheese is dispersed in H<sub>2</sub>O and protein is pptd by CCl<sub>3</sub>COOH. Filtrate is treated with pyridine and Ac<sub>2</sub>O and *A* of yellow color of citric acid complex is measured at 428 nm.

#### 16.264

#### Apparatus and Reagents

(a) *Test tubes*.—16 or 18 × 150 mm, with glass or plastic stoppers.

(b) *Trichloroacetic acid soln*.—1.836*M*. Dissolve 300 g CCl<sub>3</sub>COOH in H<sub>2</sub>O and dil. to 1 L. (*Caution: See 51.082.*)

(c) *Citrate std soln*.—0.003252*M*. Dissolve 0.9565 g trisodium citrate (C<sub>6</sub>H<sub>5</sub>O<sub>7</sub>Na<sub>3</sub>·2H<sub>2</sub>O) in H<sub>2</sub>O and dil. to 1 L.

#### 16.265

#### Preparation of Sample

Accurately weigh ca 0.5 g prepd sample, **16.015–16.018** and **16.231–16.232**, and place in porcelain mortar. Disperse by crushing with pestle, adding small portions warm H<sub>2</sub>O (60–70°). Transfer quant. to 100 mL vol. flask with ≤50 mL H<sub>2</sub>O. Let cool to room temp. and add 40 mL CCl<sub>3</sub>COOH soln, mix by swirling, dil. to vol. with H<sub>2</sub>O, and remix again. Let stand 30 min at room temp. and filter thru dry, hard paper. Discard filtrate (≥10 mL) until filtrate is clear.

#### 16.266

#### Determination

Pipet 1 mL clear filtrate into test tube. Add 1.3 mL pyridine, mix, and immediately add 5.7 mL Ac<sub>2</sub>O. Stopper tube, mix thoroly, and place in 32° H<sub>2</sub>O bath.

After 30 min, remove tube from H<sub>2</sub>O bath, let cool to room temp., dry, and measure *A* against blank at 428 nm. Convert reading to μg anhyd. citric acid by ref. to std curve.

$$\% \text{ Anhyd. citric acid} = W'/(100 \times W),$$

where *W'* = μg anhyd. citric acid from std curve and *W* = g sample.

#### 16.267

#### Preparation of Standard Curve

Transfer 0, 4, 8, 12, 16, and 20 mL citrate std soln, (c), to sep. 50 mL vol. flasks and add H<sub>2</sub>O to total vol. of ca 25 mL in each. Add 20 mL CCl<sub>3</sub>COOH soln to each, mix by swirling, dil. to vol. with H<sub>2</sub>O, and remix.

Pipet 1 mL from each flask into sep. test tubes to prep. stds contg 0, 50, 100, 150, 200, and 250 μg anhyd. citric acid, and proceed as in **16.266**.

Prep. std curve by plotting *A* against μg citric acid.

#### 16.268 Lactose in Process Cheese (64) Official Final Action

Prep. suspension as in **16.260** thru addn of Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln. Shake vigorously 1 min; add 25 g powd Na<sub>2</sub>SO<sub>4</sub> and shake 2

min; add 10 mL  $\text{H}_2\text{SO}_4$  (1+1) and shake; then add 25 mL 20% *phosphotungstic acid soln* and shake vigorously. Transfer contents of bottle to 500 mL vol. flask, cool at once to  $20^\circ$ , and dil. to vol. with  $\text{H}_2\text{O}$ . Mix thoroly, let stand 10 min, and filter thru dry folded paper. Transfer 150 mL filtrate to each of two 250 mL vol. flasks, add 10% NaOH soln to one flask until mixt. is alk. to litmus, and then add 5 g solid KCl and mix thoroly. Cool to  $20^\circ$  and dil. to vol. with  $\text{H}_2\text{O}$ . Mix well, let stand 10 min, and filter thru dry folded paper.

Det. lactose in 50 mL aliquot as in 31.038. Treat the 150 mL in second flask as in 31.026(c), using 10 mL HCl, etc. Add 10% NaOH soln until alk. to litmus, and add 5 g solid KCl. Mix thoroly, cool to  $20^\circ$ , and dil. to vol. with  $\text{H}_2\text{O}$ . Let stand 10 min. Filter if necessary thru dry paper. Det. lactose in 50 mL aliquot as before. Agreement between amts of  $\text{Cu}_2\text{O}$  reduced before and after inversion establishes absence of sucrose.

Since insol. material of cheese and phosphotungstic acid ppt occupy some space in flask as originally prepd, it is necessary to correct for this vol. From av. composition of cheese, vol. of ppt was calcd to be 14 mL. To obtain true amt lactose present, multiply all results by factor 0.97.

#### Gums in Soft Curd Cheese (65)—Official Final Action

(Not applicable to detection of alginates)

##### 16.269

##### Reagents

(a) *Benedict soln (qualitative)*.—Dissolve 17.3 g Na citrate and 10 g anhyd.  $\text{Na}_2\text{CO}_3$  in ca 80 mL hot  $\text{H}_2\text{O}$ ; dissolve 1.73 g  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  in 10 mL  $\text{H}_2\text{O}$ . Filter alk. citrate soln, add  $\text{CuSO}_4$  soln slowly with constant stirring, and dil. with  $\text{H}_2\text{O}$  to 100 mL.

(b) *Trichloroacetic acid (TCA) soln*.—(1) 50%. (2) 10%. Prep. just before use from nonhydrolyzed reagent. (Caution: See 51.082.)

##### 16.270

##### Preparation of Sample

Weigh 100 g cheese into 250 mL centr. bottle. Add hot  $\text{H}_2\text{O}$  to total vol. of 170 mL, heat in hot  $\text{H}_2\text{O}$  bath 30 min, and cool to room temp. Add 50 mL pet ether, shake, and centr. Remove pet ether layer by decantation or by use of blow-off siphon, 16.220, Notes. Repeat extn with pet ether at least twice. (Small amt of fat remaining is harmless.)

Warm bottle in hot  $\text{H}_2\text{O}$  bath to remove residual pet ether from cheese. Centr., if necessary, to break any foam. Make vol. to ca 190 mL with  $\text{H}_2\text{O}$  and add 3.5 mL  $\text{NH}_4\text{OH}$ , few drops at time, while stirring. Keep in hot  $\text{H}_2\text{O}$  bath and stir until all curd dissolves. If curd fails to dissolve completely, add few more drops  $\text{NH}_4\text{OH}$ , stir, and macerate to dissolve. Add HOAc, few drops at time, with shaking, until pH is ca 4.75 (nitrazine test paper or pH meter). Use care in approaching pH point because isoelec. point for casein is ca pH 4.73. (If acid is added very slowly with const shaking and centr. bottle is kept hot, marked sepn of casein and liq. will be noted at this point.) Stopper bottle, shake thoroly, and let stand overnight in the hot  $\text{H}_2\text{O}$  bath as  $\text{H}_2\text{O}$  cools. Check pH and centr. at 1200 rpm 10 min. Decant supernate into 250 mL beaker with 40 mL graduation mark. Do not wash ppt.

##### 16.271

##### Separation of Gum

Evap. decanted liq. on steam bath to 40 mL mark of beaker. Remove beaker from bath and cool to room temp. Disregard ppt formed during concn and add 10 mL 50% TCA soln (note directions under 16.269(b)). Replace on steam bath  $\geq 15$  min to coagulate protein. Remove beaker from steam bath, cool, transfer to 250 mL Pyrex centr. bottle with 5 mL 10% TCA soln, and

centr. at 1200 rpm 10 min. Decant supernate into another 250 mL centr. bottle and add alcohol with stirring until bottle is full. (Vol. before addn of alcohol should be  $\leq 50$  mL and ca 4 vols alcohol should be added.) Let mixt. stand 1 hr to coagulate gums. Centr. at 1800 rpm, decant, and discard liq.

Add ca 50 mL 70% alcohol to residue in bottle, stopper, and shake to break up material thoroly. Wash down stopper and sides of bottle with little 70% alcohol, centr. at 1800 rpm, decant, and drain. Add 40 mL hot  $\text{H}_2\text{O}$  to bottle and shake well to dissolve gum and disperse insol. material. Add 10 mL 50% TCA soln to bottle and heat on steam bath 15 min to coagulate any protein left after first treatment.

Remove bottle, cool, and centr. at 1200 rpm 10 min. Decant supernate into another 250 mL Pyrex centr. bottle, and fill bottle with alcohol while stirring contents. Add 0.5 mL 5%  $\text{KAl}(\text{SO}_4)_2$  soln. Shake, and let stand  $\geq 1$  hr. Centr. at 1800 rpm and decant. Add 50 mL 70% alcohol, shake to disperse material, and centr. at 1800 rpm. Decant supernate and drain. Add 40 mL hot  $\text{H}_2\text{O}$  and shake well to dissolve gum. Transfer to 50 mL conical heavy-duty centr. tube, keeping vol. to 40 mL. Centr. at 1200 rpm 10 min to remove any undissolved material, and decant supernate back into 250 mL centr. bottle. Reppt in bottle by filling with alcohol plus 1 drop HOAc. To ensure pptn of gum tragacanth and karaya, add 0.5 mL 5%  $\text{KAl}(\text{SO}_4)_2$  soln.

Let stand  $\geq 1$  hr to coagulate ppt, centr., and decant liq. If ppt is small and will not remain on bottom of 250 mL centr. bottle, centr. the alcohol and pptd gum, portion at time, at 1500 rpm 15 min in 50 mL conical heavy-duty centr. tube, until all contents of 250 mL bottle are transferred to 50 mL tube. After decanting supernate from last portion centrfd, add 40 mL 70% alcohol to tube (or bottle if tube is not used), and shake until ppt is dispersed; centr., decant, and drain.

##### 16.272

##### Detection of Gum

Add 10 mL hot  $\text{H}_2\text{O}$  to residue in tube or bottle, shake, and transfer to 50 mL beaker. Rinse tube or bottle with 10 mL hot  $\text{H}_2\text{O}$  and add rinse to beaker. Warm on elec. hot plate to dissolve gum and evap. to 10 mL. Add 2 mL HCl, cover beaker with watch glass, and boil gently 5 min. Cool, transfer to 10 mL graduate, adjust to 10 mL with  $\text{H}_2\text{O}$ , and mix. Place 1 mL aliquot in 30 mL beaker and neutze with 10% NaOH soln, using litmus paper as indicator. Remove litmus paper, add 5 mL Benedict soln, boil vigorously 2 min, and let cool spontaneously. Voluminous ppt appearing on cooling, which may be yellow, orange, or red, caused by reducing sugars formed by hydrolysis of the gums, indicates presence of gums.

#### Gelatin in Cottage Cheese

##### 16.273 Qualitative Test—Official Final Action

Thoroly mix 5 g sample with 10 mL  $\text{H}_2\text{O}$  at  $50$ – $60^\circ$  and add 5 mL  $\text{Hg}(\text{NO}_3)_2$  soln, 16.109. Shake, let stand 5 min, and filter thru medium-fast retentive paper. To filtrate add addnl 5 mL  $\text{Hg}(\text{NO}_3)_2$  soln and test as in 16.109, using filtrate so obtained. See also Note in 16.109.

##### 16.274 Sorbic Acid—Official First Action

See 20.098–20.104.

#### Residual Phosphatase (27) Official Final Action

##### 16.275

##### Reagents

(a) *Buffers*:

(1) 25-11 Barium borate-hydroxide buffer.—See 16.116(a)(1).

(2) 26-11, 27-11, 28-11, and 29-11 Barium borate-hydroxide buffers.—Prep. as in 16.116(a)(1), except use 26.0, 27.0, 28.0, or 29.0 g Ba(OH)<sub>2</sub>·8H<sub>2</sub>O, resp., instead of 25.0 g.

(b) *Buffer substrates:*

Dissolve 0.10 g phenol-free cryst. Na<sub>2</sub>C<sub>6</sub>H<sub>5</sub>PO<sub>4</sub> in 100 mL appropriate buffer, (a), specified in Table 16.03. See 16.116(b)(1) for prep of phenol-free substrate.

(c) *Protein precipitants:*

(1) 6.0–0.1 Precipitant.—Dissolve 6.0 g ZnSO<sub>4</sub>·7H<sub>2</sub>O and 0.1 g CuSO<sub>4</sub>·5H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL.

(2) 6.0 Precipitant.—Dissolve 6.0 g ZnSO<sub>4</sub>·7H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL.

For other reagents, see 16.116.

### 16.276

### Sampling

(a) *Hard cheese.*—Take sample from interior with clean Roquefort trier, place in small tube, stopper, and keep in refrigerator.

(b) *Soft and semisoft ripened cheese.*—Harden cheese by chilling in freezing compartment of refrigerator. Take special precautions to avoid contaminating sample with phosphatase that may be present on surface. Sample by either of following methods:

(1) Cut portion from end of loaf or side of cheese, extending in ≥5 cm (2") if possible, to point somewhat beyond center in case of small cheese. Cut slit 6–12 mm (¼–½") deep at least half way around portion and midway between top and bottom. Break portion into 2 parts, pulling apart so that break occurs on line with slit and taking care not to contaminate freshly exposed broken surface. Remove sample from freshly exposed surface at or near center of cheese.

(2) Remove surface of area to be sampled (e.g., end and adjacent sides), with clean knife or spatula, to depth of 6 mm (¼"). Clean instrument and hands with hot H<sub>2</sub>O and phenol-free soap, and wipe dry. Remove freshly exposed surface to same or greater depth, and repeat cleaning. Take sample from center of freshly exposed area, preferably at or near center of cheese if cheese is small.

(c) *Process cheese and cheese spreads.*—Take sample from beneath surface with clean knife or spatula.

If preservative is necessary, put 1–3 mL CHCl<sub>3</sub> in container, cover with plug of cotton, insert sample, and stopper tightly. Label "Poison, preservative added."

### 16.277

### Determination

(See 16.118.) Different kinds of cheese and cheeses of different ages have different buffering capacities and therefore require different concns of reagents. Modifications of the Ba buffer needed to produce optimal pH conditions during incubation (9.85–10.20) and of precipitant to yield uniformly clear filtrates and minimize interference during development of color under optimal pH conditions (9.3–9.4) are specified in Table 16.03.

Proceed as follows:

*Step 1.*—Weigh, on clean balance pan or watch glass, 0.50 g sample (preferably in duplicate) and place in culture tube 16 or 18 × 150 mm. Similarly weigh another sample and place in tube as control or blank. If cheese is sticky, weigh sample on piece of wax paper ca 2.5 × 2.5 cm (1 × 1") and insert paper with sample into tube. Macerate blank and test samples with glass rod ca 8 × 180 mm.

*Step 2.*—Add to blank 1.0 mL appropriate Ba buffer, Table 16.03 (without substrate), macerate with rod, leave rod in tube, and heat ca 1 min to 85–90° in beaker of boiling H<sub>2</sub>O (covered, to ensure that entire tube will be heated to 85–90°); cool to room temp., and again macerate with rod.

*Step 3.*—To each test sample add 1.0 mL appropriate Ba buffer substrate, 16.275(b), and macerate.

From this point, treat blank and test alike.

Add 9.0 mL more Ba buffer substrate (total 10.0 mL), and mix. (Rod may be left in tube during incubation. If it is removed at this point, wrap piece of ca 2.5 cm sq filter paper tightly around it and wipe it clean by rotating while withdrawing from tube. Insert paper with adhering fat in tube.) Stopper tube.

For quant. results on unknown samples, adjust pH to 10.0–10.05 by dropwise addn of 1N or 0.5N Na<sub>2</sub>CO<sub>3</sub> or HCl.

Table 16.03 Phosphatase Test Modifications for Different Kinds of Cheese and Cheese of Different Ages

Kind of Cheese	Age or Extent of Curing; Other Details	Buffer for Opt. pH <sup>a</sup> (9.85–10.20)	Precipitant	Criterion, Phenol Equivalent <sup>b</sup>

Past. proc.; ditto, pimiento; ditto, with fruits, meats, etc.	Soft, mild	25–11	6.0 <sup>d</sup>	3
	Med. firm	26–11	6.0 <sup>d</sup>	3
	Firm, sharp (incl. Swiss, gruyère)	27–11	6.0 <sup>d</sup>	3
Past. proc. cheese foods; ditto, with fruits, meats, etc.	Same as past. proc.			
Past. proc. cheese spreads; ditto, with fruits, meats, etc.	Soft, high moisture, incl. cream spreads	25–11	6.0 <sup>d</sup>	3
	Less soft, incl. blue	26–11	6.0 <sup>d</sup>	3
Cold pack, club; cold pack cheese foods; ditto, with fruits, meats, etc.	Mild-med. flavored, soft	26–11	6.0 <sup>d</sup>	3
	Sharp, firm	27–11	6.0 <sup>d</sup>	3

**Step 4.**—Immediately incubate in H<sub>2</sub>O bath 1 hr at 37–38°, mixing or shaking contents occasionally.

**Step 5.**—Heat in beaker of boiling H<sub>2</sub>O nearly 1 min (temp. of contents of tube ca 85° as detd by thermometer in another tube of same size and shape contg same vol. liq.), and cool to room temp. in vessel of cold H<sub>2</sub>O.

**Step 6.**—Pipet in 1.0 mL appropriate protein precipitant, Table 16:03, and mix thoroly (pH of mixt., 9.0–9.1).

**Steps 7–11.**—Proceed as in 16:118.

**Step 12.**—When using 0.5 g solid sample and adding total of 11.0 mL liq., multiply value of reading by 1.1 to convert to units of color or phenol equivs/0.25 g cheese. (If desired, multiply by 4.4 to convert result to phenol equivs/g.) Evaluate result by comparing with criteria of pasteurization in Table 16:03.

**Notes:** With some cheese samples of unknown history, slight deviations from optimal pH range may occur, but such deviations do not materially affect results. For example, pH values as low as 9.6 or as high as 10.35 during incubation have been found to result in av. decrease of ≤20% in amt phenol liberated. Use of 25–11 buffer substrate with samples for which 27–11 buffer substrate is specified yields pH values ≥9.8.

Trace of cloudiness in filtrate, following use of prescribed precipitant, indicates concn of Ba(OH)<sub>2</sub> in buffer was insufficient (i.e., buffer substrate was not alk. enough). For example, the 25–11 buffer, for use with unripened cheese, may yield cloudy filtrate if used with ripened cheese. Increasing concn of ZnSO<sub>4</sub> in precipitant also eliminates turbidity of filtrate.

In testing cheese of unknown history or age, information as to % solids, especially nonfat solids, is useful as indication of correct buffer to use; cheese with relatively high % nonfat solids generally requires use of relatively concd buffer to adjust pH of mixt. correctly. Av. buffer within cheese group (generally 26–11) is usually satisfactory for cheese of uncertain age.

Cottage cheese curd is heated in presence of considerable acid during manufacture, and therefore its phosphatase values are comparatively low. To increase sensitivity of test on cottage cheese, apply following modifications: Use 1.0 g sample, 27–11 buffer substrate, 2 hr incubation, 6.0–0.1 precipitant, and pasteurization criterion of 2 units/0.5 g.

To test for presence of microbial phosphatase, e.g., in surface-ripened cheeses and their processed products, (a) indicated by blue tinge in blank of Step 2, repeat detn, adding 1 mL of the Ba buffer (without substrate) to blank and heating 5 min in boiling H<sub>2</sub>O in covered beaker. If blank so treated is neg., blue tinge in original blank was due to microbial phosphatase. (b) In suspected instances in absence of blue tinge in blank of Step 2, heat sample itself 5 min at 70° to completely destroy milk phosphatase and then perform test. If pos., microbial phosphatase is present.

See also Notes under 16:118.

#### Qualitative (Screening) Method (66) Official First Action

##### 16.278

##### Reagents

(a) *Color developer.*—2.5*N* NaOH. Dissolve 10 g NaOH in 100 mL H<sub>2</sub>O.

(b) *Phenolphthalein monophosphate soln (substrate concentrate).*—See 16:121(a).

(c) *Phenolphthalein-tartrazine solns (std concentrates).*—See 16:127(b) (0.1% std). Also prep. addnl std concs contg 0.02% and 0.05% phthln by using 20 mg and 50 mg phthln, resp. Stds approximate milk contg 0.1, 0.2, and 0.5% raw milk.

(d) *Solvent.*—7.5% (v/v) *n*-butyl alcohol neutzd to pH 7.0.

##### 16.279

##### Determination

To 5.0 g cheese in 18 × 150 mm test tube add 20 mL solv. Grind with glass rod 2 min, and filter immediately thru Whatman No. 4 paper. Pipet 1 mL filtrate into each of two 15 × 100 mm test tubes and warm to 37°. To 1 tube add 1 drop (0.04 mL) substrate conc. (pH mixt. 10.0) and to other add 1 drop 0.1% std conc. Mix and incubate 30 min at 37°. Add 1 drop 2.5*N* NaOH

to each tube, mix, and compare visually. If sample soln (in tube contg substrate conc.) is less pink than std soln, cheese has been manufactured from pasteurized milk. Use 0.2 and 0.5% std concs, (c), to semiquantitate pos. test.

#### ICE CREAM AND FROZEN DESSERTS

##### Weight per Unit Volume of Packaged Ice Cream—Official Final Action

##### 16.280 ★ Method I (67) ★

Using kerosene and special overflow can. See 16:220–16:221, 11th ed.

##### Method II (68)

##### 16.281

##### Apparatus and Materials

(a) *Container.*—See Fig. 16:05. Plastic desiccator, ca 1–1.5 L (1–1.5 qt) capacity (Ace Glass Co., No. 1810, or equiv.) modified to include ca 6 mm (¼") hole in cover center for air escape and leak-free side arm tube. Clean with detergent before use and grease rims lightly.

(b) *Clamps.*—To secure desiccator lid (Hoge No. 25 binder clips (available from stationery stores), or equiv.); see Fig. 16:05.

(c) *Balance.*—Approx. 4.5 kg (10 lb) capacity and 0.3 g (0.01 oz) sensitivity.

(d) *Ice chest.*—Approx. 15–20 L (4–5 gal.) capacity, packed with solid CO<sub>2</sub>.

(e) *Immersion fluid.*—Approx. 0.001% aq. polysorbate 80 (Tween 80) soln. Prep. ca 4 L for each detn and cool to 4±4°.

##### 16.282

##### Determination

Pack and store samples overnight in solid CO<sub>2</sub>. Unwrap hard frozen sample. If sample is 0.5 gal. or larger unit, break by scoring with chisel or other sharp instrument and driving knife or wedge into block along scored line. Quickly det. wt in air (*W<sub>a</sub>*, oz) of piece selected for wt/vol. detn and return to ice chest.

Place container on level surface and secure lid in place with 4 clamps. Completely fill container thru inlet tube with chilled immersion fluid dispensed from separator with rubber tubing attached. Wipe outer surface dry and det. wt (*W<sub>p</sub>*, oz).

Place container in sink or on drainboard and remove lid. Place previously weighed sample piece in container and secure lid with 4 clamps. Fill container completely with immersion fluid, letting all air bubbles escape thru air hole in lid. Wipe outer surface and det. wt (*W<sub>i</sub>*, oz).

Wt per unit vol. (lb/gal.) = (*W<sub>a</sub>* × 8.338)/[*W<sub>a</sub>* + (*W<sub>p</sub>* − *W<sub>i</sub>*)], where 8.338 = density of H<sub>2</sub>O at 0–8° (lb/gal.).

##### 16.283 Preparation of Sample (69)—Procedure

Cut frozen blocks of product into ca ½ pt pieces. Select 2 or 3 pieces at random, place in cup of high-speed blender, and close tightly. Let soften at room temp. and mix (2 min for plain products and ≤7 min for those contg nuts or hard candy chips). Do not let temp. exceed 12° at any time during softening and mixing steps. If fat sepn or "churning" occurs, discard sample and repeat, using shorter mixing time. Immediately pour mixt. into wide-mouth jar and cap tightly. If allowed to stand, shake vigorously before removing samples.

##### 16.284 Total Solids (70)—Official Final Action

Into round, flat-bottom dish ≥5 cm diam., quickly weigh 1–2 g sample. (Sample may be weighed by means of short, bent, 2

★ Surplus method—see inside front cover.

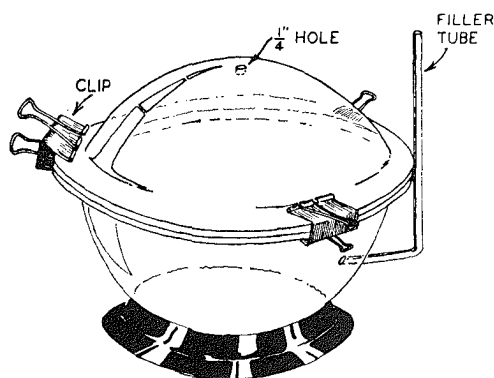

FIG. 16.05 Modified plastic desiccator

mL measuring pipet.) Heat on steam bath 30 min and then in air oven 3.5 hr at 100°. Cool in desiccator and weigh quickly to avoid absorption of moisture.

#### Nitrogen—Official Final Action

##### 16.285 Kjeldahl Method

Proceed as in 2.057, using 4–5 g sample.  
 $\% \text{N} \times 6.38 = \% \text{ "protein."}$

##### 16.286 Dye Binding Method

See 16.037–16.041.

#### Fat

##### 16.287 Roese-Gottlieb Method (71)—Official Final Action

Accurately weigh 4–5 g thoroly mixed sample directly into fat-extn flask or tube, using free-flowing pipet; dil. with H<sub>2</sub>O to ca 10 mL, working sample into lower chamber and mix by shaking. Add 2 mL NH<sub>4</sub>OH, mix thoroly, and heat in H<sub>2</sub>O bath 20 min at 60° with occasional shaking. Cool, and proceed as in 16.059, beginning "Add 10 mL alcohol and mix well."

##### 16.288 Separation of Fat from Ice Cream Official Final Action

(Caution: See 51.011, 51.039, and 51.054.)

Melt sample and screen out any large pieces of fruit, nuts, etc. on No. 20 sieve. Place 300 mL melted sample in 1 L separator, add 100 mL H<sub>2</sub>O and 50 mL NH<sub>4</sub>OH, and shake well. Add 200 mL alcohol and shake 1 min. Add 200 mL ether and shake 1 min. Add 200 mL pet ether and shake 1 min. Let stand until emulsion breaks, and drain and discard lower layer. Add 25 g anhyd. Na<sub>2</sub>SO<sub>4</sub>, shake, and decant thru rapid folded paper. Evap. ether and alcohol, and dry fat overnight at 55°. Examine fat as in Chap. 28.

##### 16.289 Lactic Acid—Official Final Action

See 16.027–16.031.

#### Gums

##### Infrared Method (72)—Official Final Action

(Guar flour gum and locust bean gum cannot be distinguished by this method. Karaya gum cannot be identified when isolated by this method.)

##### 16.290

##### Reagents

(a) *Dioxane*.—Tech. grade is satisfactory. (Caution: Vapors are obnoxious and harmful.)

(b) *Trichloroacetic acid (TCA) soln.*—50%. See 16.269(b).

(c) *Organo-silicone compound*.—To prep. nonwettable surface. Desicote® (Beckman Instruments) has been found satisfactory.

##### 16.291

##### Apparatus

(a) *Infrared spectrophotometer*.—Recording, for operation in 2–15  $\mu\text{m}$  region.

(b) *Water-repellent plate*.—Wash 7–10 cm (3–4") glass sq thoroly with detergent, rinse, and dry with towel. Dip glass rod in organo-silicone compd and streak adhering liq. across plate. Repeat streaking several times. Rub plate with lens paper to distribute evenly; then rub with clean lens paper to remove excess. Plate is now ready for use. Wash plate with cold H<sub>2</sub>O and dry with towel after each use. Plate can be reused as long as it remains nonwettable.

##### 16.292

##### Preparation of Sample

Weigh 50 g sample of frozen dessert into 250 mL centrf. bottle and heat to 60° in H<sub>2</sub>O bath. Add 150 mL dioxane, shake vigorously 2 min, and centrf. 10 min at 1800 rpm. Decant and discard supernate. Add 30 mL ether, and shake vigorously to break mass at bottom, using rod if necessary. Decant ether and repeat ether wash once. Heat in H<sub>2</sub>O bath to remove residual ether. Add 30 mL 80° H<sub>2</sub>O and shake vigorously 2 min to dissolve or disperse residue.

##### 16.293

##### Separation of Gum

Add 20 mL 50% TCA soln and heat to 60° in H<sub>2</sub>O bath. Shake 1 min and centrf. 10 min at 1200 rpm. Decant soln thru folded paper into second centrf. bottle, and discard residue.

Fill centrf. bottle with alcohol, add 1 mL satd NaCl soln, mix, and let stand until coagulation occurs. If ppt does not form, gums are absent. (Let opalescent solns stand overnight to facilitate pptn. Centrf., and discard if no ppt is present.) Centrf. 10 min at 1800 rpm and immediately decant and discard supernate.

Purify pptd gum by adding 30 mL 80° H<sub>2</sub>O and shake vigorously to dissolve or disperse ppt. Fill centrf. bottle with alcohol, add 1 mL satd NaCl soln and 1 drop HCl (1+1), mix, let ppt coagulate, centrf. 10 min at 1800 rpm, decant, and discard supernate. Repeat purification step twice.

##### 16.294

##### Detection of Gum

(a) *Chemical test for small amounts*.—Scrape small amt of pptd gum from centrf. bottle with spatula and transfer to 50 mL beaker with ca 10 mL hot H<sub>2</sub>O. Add 2 mL HCl and boil 5 min. Neutze to multirange indicator paper, using 30% NaOH soln first and completing with 10% NaOH soln. Remove paper and continue as in 16.272, beginning "... add 5 mL Benedict soln, ..."

(b) *Chemical test for entire precipitate*.—If IR spectrum is not desired, spectrum indicates presence of  $\geq 2$  gums, or pptd gum will not form film (as with karaya), proceed as in 16.272, beginning "Add 10 mL hot H<sub>2</sub>O ..."

(c) *Infrared method*.—(May not be applicable to mixts of gums.) Dissolve or disperse residue in 35 mL H<sub>2</sub>O. Prep. film as in 16.295, obtain IR spectrum against air, and compare with spectra of ref. gums.

##### 16.295

##### Preparation of Gum Films

Place H<sub>2</sub>O-repellent glass plate over 5 cm (2") opening on steam bath. Pour enough of aq. gum soln on plate to form circle ca 5 cm diam. (Vol. required to produce film of sufficient area

to cover light path of app. and of thickness to produce characteristic spectrum varies depending upon nature of gum and its concn.) Heat plate until film is dry and remove film with forceps. If film sticks to plate, remove with razor blade or tissue lifter. Transfer film to beaker and dry 15–30 min at 100°. (Excessive heating may char some gums.) Place piece of film between 2 salt plates and obtain IR spectrum against air.

#### 16.296 *Preparation of Reference Gum Films*

Disperse 0.2 g gum in 30 mL 80° H<sub>2</sub>O and add 20 mL 50% TCA soln. Continue as in **16.293**, beginning "Shake 1 min and centr. 10 min at 1200 rpm."

#### 16.297 *Alginates in Chocolate Frozen Desserts* **Official Final Action**

See **13.058–13.059**.

#### 16.298 *Gelatin—Official Final Action*

Using 10 g sample, proceed as in **16.109**.

#### 16.299 *Color Additives—Official Final Action*

Curdle 150–200 g melted sample by adding equal vol. H<sub>2</sub>O and 10–20 mL HOAc. Heat mixt. to 70–80°, with stirring, and let cool. Continue as in **16.113** and **16.218**, and in Chap. **34** for detection of oil-sol. synthetic dyes and annatto.

#### 16.300 *Residual Phosphatase (27)—Official Final Action*

Melt portion of sample and let it remain melted ≥1 hr before testing. Then proceed as in **16.118** except as follows:

In *Step 3*, proceed as for milk in case of sherbets; for ice cream, substitute buffer substrate made by dissolving Na<sub>2</sub>C<sub>6</sub>H<sub>5</sub>PO<sub>4</sub> in mixt. of 4 parts Ba buffer, **16.116(a)(1)**, and 1 part H<sub>2</sub>O.

In *Step 6*, proceed as for milk in case of sherbets; for ice cream, ppt with 1.0 mL soln contg 4.5 g ZnSO<sub>4</sub>·7H<sub>2</sub>O and 0.1 g CuSO<sub>4</sub>·5H<sub>2</sub>O/100 mL.

Controls are essential since phenols may be present from flavors or plastic containers.

## 17. Eggs and Egg Products

### 17.001 Collection and Preparation of Sample (7)—Procedure

No simple rules can be made for collection of sample representative of av. of any particular lot of egg material, as conditions may differ widely. Experienced judgment must be used in each instance. For large lots, preferably draw several samples for sep. analyses rather than attempt to get one composite representative sample. Sampling for microbiological examination, if required, should be performed first; see 46.003–46.004.

(a) *Liquid eggs*.—Obtain representative container or containers. Mix contents of container thoroly and draw ca 300 g. (Long-handle dipper or ladle serves well.) Keep sample in hermetically sealed jar in freezer or with solid CO<sub>2</sub>. Report odor and appearance.

(b) *Frozen eggs*.—Obtain representative container or containers. Examine contents as to odor and appearance. (Condition of contents can be detd best by drilling to center of container with auger and noting odor as auger is withdrawn. If impossible to secure individual containers, samples may consist of composite of borings from contents of each container.) Take borings diagonally across can from ≥3 widely sepd parts, starting 2–5 cm in from edge and extending to opposite side as near to bottom as possible. Pack shavings tightly into sample jar and fill it completely to prevent partial dehydration of sample. Seal jar tightly and store in freezer or with solid CO<sub>2</sub>. Before analyzing, warm sample in bath held at <50°, and mix well.

(c) *Dried eggs*.—Obtain representative container or containers. For small packages, take entire parcel or parcels for sample. For boxes and barrels, remove top layer to depth of ca 15 cm (6") with scoop or other convenient instrument. Draw small amts of sample totaling 300–500 g from accessible parts of container and place in hermetically sealed jar. Report odor and appearance. Prep. sample for analysis by mixing 3 times thru domestic flour sifter to thoroly break up lumps. (Grind flake albumen samples to pass entirely thru No. 60 sieve. Mix well.) Keep in hermetically sealed jar in cool place.

### Yolk Color (2)—Official Final Action

#### 17.002 Preparation of Standard Carotene Solutions

*Carotene std solns.*—(1) *Stock soln.*—Approx. 6 µg/mL. Accurately weigh ca 5 g 0.03% β-carotene soln (available in sealed 5 mL (in Et laurate) ampuls, stable ca 6 months under refrigeration, from Poultry and Egg Institute of America, 4350 Oakton St, Skokie, IL 60076; exact assay supplied with ampul). Transfer to 250 mL g-s vol. flask with acetone and dil. to vol. with acetone. (2) *Working solns.*—Dil. to 100 mL with acetone 10, 20, 30, 45, 60, and 75 mL stock soln to obtain solns contg ca 0.6, 1.2, 1.8, 2.7, 3.6, and 4.5 µg/mL, resp. Use acetone for blank.

Solns are stable ca 1 week in dark under refrigeration.

#### 17.003 Preparation of Standard Curve

Det. % *T* or *A* of dild std solns as soon as possible with spectrophtr at 450 nm or with instrument with suitable filter system such as Klett photometer with No. 44 filter, Evelyn photoelec. colorimeter with 440 filter, or with Cenco-Sanford-Sheard Photometer, Industrial Type B-2 with 410 filter. Plot µg β-carotene against % *T*, omitting values >90% or <10%, on semilog paper or against *A* on plain coordinate paper.

#### 17.004

#### Determination

Weigh sample contg ca 1.0 g egg yolk solids (1 g dried yolk, 2.5 g liq. yolk, 5.0 g liq. whole egg, or equiv.) into 150 mL beaker. Add ca 1–2 mL acetone and stir to smooth paste. Add ca 50 mL acetone, mix, and filter. Add ca 2.5 mL H<sub>2</sub>O before the acetone to products contg sugar or salt. Wash material onto Whatman No. 4 filter paper, or equiv., with successive small portions of acetone, catching filtrate in g-s 100 mL vol. flask. Dil. to vol. with acetone. Det. *A* or % *T* as soon as possible. Report yolk color equiv. to µg β-carotene/g sample.

#### 17.005 Carotenoids—Official Final Action

See 14.156–14.160.

#### Total Solids

#### Vacuum Method (3)—Official Final Action

#### 17.006

#### Apparatus

*Vacuum oven.*—Connected with pump to maintain pressure ≤25 mm Hg (3.3 kPa) and provided with thermometer passing into oven with bulb near samples. Connect H<sub>2</sub>SO<sub>4</sub> gas-drying bottle to oven for admitting dry air to release vac.

#### 17.007

#### Determination

(a) *Liquid eggs*.—Accurately weigh by difference, using weighing buret, ca 5 g samples, 17.001(a) or (b), in covered dish previously dried at 98–100°, cooled in desiccator, and weighed soon after coming to room temp. Remove cover and evap. most of H<sub>2</sub>O by heating on steam bath. Replace cover loosely and complete drying in vac. oven as in (b).

(b) *Dried eggs*.—Weigh ca 2 g sample, 17.001(c), in covered dish previously dried at 98–100°, cooled in desiccator, and weighed soon after coming to room temp. Loosen cover (do not remove) and heat at 98–100° to const wt (ca 5 hr) in vac. oven. Admit dry air into oven to bring to atm. pressure. Immediately tighten cover of dish, transfer to desiccator contg fresh efficient desiccant, and weigh soon after coming to room temp. Report as % total solids.

#### Nitrogen (4)—Official Final Action

#### 17.008

#### Preparation of Sample

(a) *Liquid eggs*.—Weigh 2–3 g well mixed sample, 17.001(a) or (b), by difference into 500 mL Kjeldahl flask.

(b) *Dried eggs*.—Transfer ca 1 g prepd sample, 17.001(c), accurately weighed, to 500 mL Kjeldahl flask.

#### 17.009

#### Determination

Det. N as in 2.057. Distil NH<sub>3</sub> into 30–50 mL 0.1*N* std acid.

#### Water-Soluble Nitrogen and Crude Albumin

#### Nitrogen in Liquid Eggs (5)

#### Official Final Action

#### 17.010

#### Preparation of Solution

Accurately weigh, by difference, into 250 mL vol. flask contg 150 mL H<sub>2</sub>O, ca 10 g well mixed sample 17.001(a) or (b), and mix gently. Add 5 mL 0.01*N* HOAc for each g egg solids, dil. to

vol. with  $H_2O$ , shake gently, and filter thru 18.5 cm folded paper, covering filter with watch glass during filtration. If filtrate is cloudy, let filtration continue until drops of filtrate are clear, change receiver, and return cloudy filtrate to filter.

**17.011****Determination**

(a) *Water-soluble nitrogen*.—Transfer 50 mL clear filtrate to 500 mL Kjeldahl flask, and det. N as in 2.057. Calc. N and report as %  $H_2O$ -sol. N.

(b) *Crude albumin nitrogen*.—Transfer 100 mL clear filtrate to 200 mL vol. flask, add 15 mL NaCl soln (28 g NaCl dild to 300 mL), fill nearly to vol. with alcohol, and mix. Cool to room temp., dil. to vol. with alcohol, mix, and let stand overnight. Filter, transfer 100 mL filtrate to 500 mL Kjeldahl flask, and det. N as in 2.057. Calc. % N, subtract it from %  $H_2O$ -sol. N, and report difference as % crude albumin N.

**Fat by Acid Hydrolysis (6)—Official Final Action****17.012****Preparation of Solution**

(a) *Liquid eggs*.—From well mixed sample, 17.001(a) or (b), accurately weigh, by difference, into Mojonnier fat-extn tube ca 2 g yolks, 3 g whole eggs, or 5 g whites. Slowly, with vigorous shaking, add 10 mL HCl, set tube in  $H_2O$  bath heated to 70°, bring to boiling, and continue heating at bp 30 min, shaking tube carefully every 5 min. Remove tube, add  $H_2O$  to nearly fill lower bulb of tube, and cool to room temp.

(b) *Dried eggs*.—Transfer 1 g well mixed sample to fat-extn tube, slowly add 10 mL HCl (4+1), washing down any egg particles adhering to sides of tube, and proceed as in (a).

**17.013****Determination**

To extn tube contg treated sample, 17.012, add 25 mL ether and mix. Add 25 mL redistd pet ether (bp <60°), mix, and let stand until solv. layer is clear. Proceed as in 14.019, beginning "Draw off as much as possible . . ." but omitting filtration.

**Lipids and Lipid Phosphorus ( $P_2O_5$ ) (7)  
Official Final Action****17.014****Reagents**

(a) *Mixed solvent*.—Equal vols  $CHCl_3$  and absolute alcohol.  
(b) *Alcoholic sodium hydroxide soln*.—Prep.  $CO_2$ -free soln by dissolving 100 g NaOH in 100 mL  $H_2O$ . Let stand until clear, or filter thru hardened paper previously soaked in alcohol. (5 mL NaOH soln contains ca 4 g NaOH.) Dissolve 50 mL of this soln in 900 mL alcohol and dil. with alcohol to 1 L.

**17.015****Preparation of Solution**

(a) *Liquid eggs*.—Accurately weigh, by difference, ca 4 g well mixed sample, 17.001(a) or (b), into 100 mL vol. flask, and add 25 mL mixed solv. very slowly (dropwise) from pipet, shaking constantly until proteins coagulate and are then thoroly broken up. Add 60–65 mL addnl solv. and let stand 1 hr, shaking every 5 min. Dil. to vol. with solv., mix, and let mixt. stand until clear.

(b) *Dried eggs*.—Transfer 2 g well mixed sample, 17.001(c), to 100 mL vol. flask, add 85–90 mL mixed solv., and let stand 1 hr, mixing every 5 min. Proceed as in (a).

**17.016****Determination**

(a) *Lipids*.—Transfer 50 mL aliquot to 150 mL beaker and evap. ext to dryness on steam bath. (Elec. fan or gentle blast of dry air may be used to hasten evapn.) Place beaker in oven 5–10 min at 100° to remove any remaining  $H_2O$ . Dissolve dry ext in 5–10 mL  $CHCl_3$ , and filter into weighed 100 mL Pyrex

beaker thru pledget of cotton packed into stem of funnel, transferring all sol. ext from bottom and sides of beaker with  $CHCl_3$ . Finally wash funnel and stem tip. (Filtrate should be clear.) Evap.  $CHCl_3$  on steam bath and dry beaker and contents in oven at 100° to const wt (ca 90 min). Let beaker stand in air to const wt (ca 30 min), weigh, and report % lipids.

(b) *Lipid phosphorus ( $P_2O_5$ )*.—Dissolve dried lipids in 2–3 mL  $CHCl_3$ , add 10–20 mL alc. NaOH soln, evap. to dryness on steam bath, using care to avoid spattering, and place beaker in oven 30 min at 100° to remove any remaining  $H_2O$ . Transfer beaker while hot to furnace heated to 500° (faint red), and keep at this temp. 1 hr. Cool, add few drops  $H_2O$ , and break up residue with flat-end glass rod. Cover beaker with watch glass, slowly add 5 mL  $HNO_3$  (1+3), mix, wash watch glass, and filter, collecting filtrate in 300 or 500 mL erlenmeyer. Thoroly wash charred material and filter paper with  $H_2O$ .

Det. P in filtrate as in 7.119, using 20–50 mL molybdate soln. Report % lipid  $P_2O_5$  in eggs.

**Cholesterol (8)—Official Final Action****Separation of Unsaponifiable Matter****17.017****Reagents**

(a) *Concentrated potassium hydroxide soln*.—Dissolve 60 g KOH in 40 mL  $H_2O$ .

(b) *Dilute potassium hydroxide soln*.—Dissolve 10 g KOH in 1 L  $H_2O$ .

(c) *Ether*.—USP or ACS, peroxide-free. Test immediately before use.

(d) *Dried ether*.—Immediately before use, shake peroxide-free ether with anhyd.  $CaCl_2$  equal to 10% of the vol. of the ether, and filter.

(e) *Anhydrous sodium sulfate*.—Powder to pass No. 60 sieve.

**17.018****Apparatus**

(a) *Separators*.—One 250 mL and one 500 mL. Wash separators free of grease. Must be ether-tight when lubricated only with  $H_2O$ .

(b) *Filtration bell jar*.—Large enough to hold 300 mL erlenmeyer and provided with air-leak valve to control vac.

(c) *Fritted glass filter*.—Fine porosity.

**17.019****Determination**

(Caution: See 51.011, 51.039, and 51.054.)

Accurately weigh into 125 mL erlenmeyer ca 2.5 g whole egg, 1.5 g yolk, 1 g dried whole egg, or 0.7 g dried yolk, and add 10 mL concd KOH soln. Cover with small watch glass and heat 3 hr on steam bath, swirling occasionally to disintegrate any lumps. Cool until just warm, add 30 mL alcohol, and swirl until all insol. matter is finely dispersed. Add 50 mL ether, mix thoroly by swirling, and transfer to 500 mL separator. Wash flask with 2 addnl 50 mL portions ether and thoroly mix ether soln by swirling. Wash saponification flask with 100 mL dil. KOH soln, pour soln slowly into separator, while gently swirling liq., and continue gentle swirling 10–15 sec. Let liq. sep. (ca 10 min) and slowly drain soap soln into 250 mL separator, but do not drain any emulsion or insol. matter at interface. Rinse down sides of 500 mL separator with 10 mL dil. KOH soln and drain this into smaller separator. Add 50 mL ether to smaller separator and shake vigorously. After liq. seps, discard lower layer. Add ether layer to soln in large separator, rinsing 250 mL separator with 10 mL ether. Wash ether soln as before with 100 mL dil. KOH soln, keeping any insol. matter or emulsion in separator. Add 20 mL HCl (1+4) to ether, swirl, add 100 mL  $H_2O$ , and swirl again. Discard acid washings.

Wash ether soln as before with 2 addnl 100 mL portions dil. KOH soln. Test portion of last washings for soap by acidifying with HCl (1+4) (acidified washings should be clear or only faintly turbid). If necessary, repeat washing with dil. KOH soln until acidified washings are clear. Wash ether soln by successively swirling with 50 mL H<sub>2</sub>O, 50 mL H<sub>2</sub>O contg 0.5 mL 0.1N HCl, and 2 addnl 50 mL portions H<sub>2</sub>O. Finally, drain as much H<sub>2</sub>O as possible without loss of ether soln. Filter ether soln into dry 300 mL erlenmeyer thru 15 g layer Na<sub>2</sub>SO<sub>4</sub> on fritted glass filter, using no suction for first few mL and then gentle suction for remainder. Rinse separator and filter successively with 10, 5, 5, and 5 mL ether. Rinse filter stem with ether, add porcelain chip to flask, and evap. ether on steam bath.

Dissolve residue in 20 mL dried ether, transfer thru small short-stem funnel to 50 mL erlenmeyer contg porcelain chip, and rinse with 10, 5, and 5 mL dried ether. Approx. unsaponifiable matter can be detd by collecting ether solns in previously dried and weighed flask as follows: Dry flask contg chip, and similar flask as counterpoise, 1 hr at 100–105°; remove from oven and place near balance 30 min; weigh flask, using counterpoise. Evap. ether on steam bath. Wipe flask with clean towel, dry, and weigh with counterpoise as before. From wt unsaponifiable matter, deduct blank obtained from reagents used, detd similarly.

#### Determination of Cholesterol

##### 17.020

##### Reagents

(a) *Ice*.—For 4 detns have available ca 12 L (3 gal.) crushed ice.

(b) *Bromine soln*.—(Caution: See 51.047.) Weigh, to 0.1 g, narrow-mouth, g-s 25 mL flask contg 5 mL CCl<sub>4</sub>. Add 0.6 mL Br from graduated 1.0 mL pipet, weigh again, and dil. with CCl<sub>4</sub> to calcd final concn of 0.22±0.02 g Br/mL. Use reagent within 48 hr after prepn.

(c) *Acetic acid soln*.—Pipet 200 mL HOAc into 250 mL g-s vol. flask; dil. to vol. with H<sub>2</sub>O, mix cautiously, dil. to vol., and mix again.

(d) *Asbestos*.—Prep. asbestos as in 31.037.

(e) *Sand*.—Pass clean sand thru No. 60 sieve and treat with warm HCl until exts are practically colorless. Wash, dry, and ignite.

(f) *Sodium hypochlorite soln*.—Dissolve 88 g NaOH (Caution: See 51.037 and 51.047) in 200 mL H<sub>2</sub>O in wide-mouth 3 L flask. Add ca 1.5 L crushed ice and pass in Cl until 71 g is absorbed; dil. to 2 L and store in dark bottles in refrigerator. (Soln should be alk. to phthln.) Before use, check concn of available Cl as follows: Pipet 5 mL into flask contg soln of 2 g KI in 100 mL H<sub>2</sub>O, add 5 mL 6N HCl, and titr. with 0.1N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. Soln should be equiv. in available Cl to 0.95–1.05N NaOCl. Reagent or com. NaOCl soln, 5%, checked for concn as above, is also satisfactory.

(g) *Sodium formate soln*.—Prep. aq. soln contg 0.5 g NaCHO<sub>2</sub>/mL.

(h) *Hydrochloric acid*.—Approx. 6N; mix 520 mL HCl with H<sub>2</sub>O and dil. to 1 L.

(i) *Methyl red indicator*.—Dissolve 0.5 g Me red in 50 mL alcohol, dil. to 100 mL with H<sub>2</sub>O, and filter. Since soln must be free from insol. matter, refilter immediately before use, if necessary.

(j) *Potassium iodide soln*.—20%. (Soln must be colorless when acidified with HCl.)

(k) *Starch soln*.—1% soln of sol. starch.

(l) *Sodium thiosulfate soln*.—0.02N. Prep. daily by dilg 0.1N soln, 50.037–50.038.

(m) *Potassium hydroxide soln*.—Dissolve 10 g KOH in 10 mL H<sub>2</sub>O.

(n) *Ammonium molybdate soln*.—Dissolve 5 g (NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub>·4H<sub>2</sub>O in 100 mL H<sub>2</sub>O.

##### 17.021

##### Apparatus

(a) *Ice bath*.—Container holding ca 4 L, 10–15 cm deep, filled with crushed ice.

(b) *Mohr pipets*.—One graduated to 0.01 mL; one graduated to 0.1 mL.

(c) *Filtration bell jar*.—Size to hold 300 mL erlenmeyer, connected to vac. by 2-way stopcock.

(d) *Device for filtering at 0°*.—Filter tube of Knorr extn tube style, ca 20 mm id, with body ca 11 cm long and stem 6–8 mm od, ca 10 cm long, provided with removable, close fitting perforated Ni, monel metal, glass, or porcelain disk at bottom of larger tube. (Allihn fritted glass filter, coarse porosity, Ace Glass, Inc. No. 7195-06 with 10 cm stem is suitable.)

Remove stem at apex from 60° Bunsen funnel, 11 cm diam. Enlarge opening at apex to ca 1 cm diam. by grinding or grating off glass. Cut ca 1 cm from end of 1-hole rubber stopper of size that fits snugly in opening of funnel. Pass stem of filter tube thru stopper in funnel apex and then thru stopper in bell jar.

Prep. mat of asbestos, (d), 6–8 mm thick in filter tube and cover with ca 12 mm layer of sand, (e). (Caution: See 51.086.)

##### 17.022

##### Determination

Pack Br soln and 25 mL graduate in ice. Pack ice around filter tubes, taking care none gets into filters. Cool HOAc soln to ca –5° in ice-NaCl mixt.

Wash down sides of 50 mL erlenmeyers contg unsaponifiable matter, while rotating, with 2.0 mL absolute ether delivered from Mohr pipet; stopper with cork, swirl until porcelain chips no longer stick to flasks, and pack flasks in ice bath up to necks ≥10 min. To one of flasks add, from Mohr pipet, 0.20 mL cold Br soln, mix by swirling, stopper, and replace in ice bath. Start this operation at 3 min intervals with other flasks (4 detns can be made at one time if bell jars are available).

After 10 min, rapidly add 15 mL HOAc soln from cold 25 mL graduate, swirl 3 min while holding in ice-H<sub>2</sub>O, and replace in ice bath 10 min. With suction on, pour all mixt. down stirring rod into filter tube, leaving rod in filter. Wash down sides of flask with 5 mL cold HOAc soln and replace in ice bath. When liq. in filter just recedes below surface of sand, add HOAc from flask. Repeat washing similarly with 5 mL HOAc soln and suck filter free of excess liq. Wash flask and filter with cold H<sub>2</sub>O, filling filter tube ca 3 times. Drain flask thoroly and apply suction to filter until drops of H<sub>2</sub>O cease to fall from stem. Remove ice pack from around filter tube and discard filtrate and washings.

Place 300 mL erlenmeyer under filter so that stem projects well into neck of flask. Wash filter tube and filter with 10 mL alcohol; 10, 5, and 5 mL portions ether; and finally with 10 mL alcohol, gently stirring sand with each portion of solv. and letting mixt. stand ca 1 min before applying suction. Wash stem of filter with few mL ether, add 1 mL KOH soln, mix, and wash down sides of flask with 5 mL ether. Completely evap. ether and alcohol on steam bath, finally using stream of clean air to remove last of alcohol vapors.

Add 40 mL hot H<sub>2</sub>O to residual alk. liq., mix, and neutze alkali with 6N HCl, using 1 drop Me red. (This neutzn need be only approx.) Add 10 g NaCl, 3 g NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O, and 20 mL NaOCl soln. Bring soln just to vigorous boiling, remove from heat, and immediately add, with care, 5 mL NaCHO<sub>2</sub> soln. Cool, and dil. to ca 150 mL with H<sub>2</sub>O. Add 5 mL KI soln, 1 or 2 drops NH<sub>4</sub> molybdate soln, and 25 mL 6N HCl. Titr. rapidly at once with Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, using starch soln as indicator. Correct titer for

blank detn on reagents, starting at point where KOH soln is added to alcohol-ether soln.

$$\text{mg Cholesterol} = 0.55 + 0.688 \times \text{mL } 0.02N \text{ Na}_2\text{S}_2\text{O}_3$$

### Total Phosphorus ( $\text{P}_2\text{O}_5$ ) (9)—Official Final Action

#### 17.023

#### Preparation of Solution

(a) *Liquid eggs*.—From well mixed sample, **17.001(a)** or (b), accurately weigh, by difference, into 250 mL Pyrex beaker, ca 2 g yolks, 4 g whole eggs, or 10 g whites. Add 20 mL 10%  $\text{Na}_2\text{CO}_3$  soln and evap. to dryness on hot plate or in oven overnight at 100–105°. Transfer beaker while hot to furnace at 500° (faint red), and keep at this temp. 1 hr. Cool, add few drops  $\text{H}_2\text{O}$ , break up residue with flat-end glass rod, and cover beaker with watch glass; slowly add 10 mL  $\text{HNO}_3$  (1+3) while stirring, mix, wash watch glass, and filter, collecting filtrate in 300 or 500 mL erlenmeyer. Thoroughly wash charred material and filter with  $\text{H}_2\text{O}$ .

(b) *Dried eggs*.—Transfer 1 g well mixed sample, **17.001(c)**, to 150 mL Pyrex beaker, add 20 mL 10%  $\text{Na}_2\text{CO}_3$  soln, and proceed as in (a).

#### 17.024

#### Determination

Det.  $\text{P}_2\text{O}_5$  in prepd filtrate as in **7.119**, using 40–50 mL molybdate soln. Report as total  $\text{P}_2\text{O}_5$ .

### Chloride (10)—Official Final Action

#### 17.025 Method I

(a) *Liquid eggs (in absence of added salt)*.—From well mixed sample, **17.001(a)** or (b), accurately weigh, by difference, into 150 mL Pyrex beaker, ca 4 g yolks, 7 g whole eggs, or 10 g whites; add 20 mL 10%  $\text{Na}_2\text{CO}_3$  soln, mix, and evap. to dryness on hot plate or overnight in oven at 100°. Transfer beaker while hot to furnace at 500° (faint red), and keep 1 hr at 500°. Cool, add few drops  $\text{H}_2\text{O}$ , and break up residue with glass rod. Add 50 mL  $\text{H}_2\text{O}$ , cover beaker with watch glass, slowly add 20 mL  $\text{HNO}_3$  (1+3), and wash watch glass. Mix, filter, and wash charred material and filter paper thoroughly with  $\text{H}_2\text{O}$ . Proceed by one of following alternatives:

(1) To combined filtrate and washings add known vol. 0.1*N*  $\text{AgNO}_3$  in slight excess and proceed as in **3.074**.

(2) Collect filtrate and washings in 250 mL vol. flask, keeping total vol. filtrate  $\leq 180$  mL. Add known vol. 0.1*N*  $\text{AgNO}_3$  in slight excess and dil. to vol. Filter, and using aliquot of filtrate, proceed as in **3.074**, beginning "... add 5 mL ferric indicator ..."

(b) *Liquid eggs (in presence of added salt)*.—From well mixed sample, **17.001(a)** or (b), accurately weigh 1–2 g, by difference, into 150 mL Pyrex beaker, and proceed as in (a).

(c) *Dried eggs*.—From well mixed sample, **17.001(c)**, transfer 2 g whole eggs or yolks or 1 g whites to 150 mL Pyrex beaker, and proceed as in (a).

#### 17.026 Method II (11)

From well mixed sample, **17.001(a)**, (b), or (c), accurately weigh, by difference, ca 4 g yolks, 7 g whole eggs, or 10 g whites; or transfer 2 g dried whole eggs or yolks or 1 g dried whites to 300 mL erlenmeyer. Add known vol. 0.1*N*  $\text{AgNO}_3$  in slight excess and 20 mL  $\text{HNO}_3$ , and place on steam bath 15–30 min. Add 15 mL 5%  $\text{KMnO}_4$  soln and let stand 60–90 min longer on steam bath. Cool to  $\leq 25^\circ$ ; add 75 mL  $\text{H}_2\text{O}$  and 1 mL *nitrobenzene* (or 1 mL for each 50 mg NaCl present); stopper flask, and shake vigorously to coagulate ppt. Add 5 mL satd ferric alum indicator and titr. with 0.1*N* thiocyanate soln to end point that persists after soln stands 15 min. (Make titrn at  $\leq 25^\circ$ ;

soln is yellow-green before end point and yellow-orange at end point.) At first permanent color change, note buret reading and time; stopper flask, shake vigorously, and let stand 15 min. If soln fades, add thiocyanate soln in half-drop portions until end point color reappears. From mL  $\text{AgNO}_3$  used, calc. NaCl after deducting blank detd on reagents, using ca 0.25 g sucrose instead of egg.

#### 17.027 Potentiometric Method

See **32.025–32.030**.

### Glucose and Sucrose (12)—Official Final Action

#### 17.028

#### Preparation of Solution

(a) *Liquid eggs*.—Accurately weigh, by difference, ca 25 g well mixed sample, **17.001(a)** or (b), into 250 mL vol. flask contg 1 g  $\text{CaCO}_3$  and 50 mL 5% NaCl soln. Add 130 mL alcohol with continuous mixing. Let stand few min for gas bubbles to rise to surface, cool to room temp., dil. to vol. with  $\text{H}_2\text{O}$ , mix, and filter (18.5 cm folded paper). Transfer 150 mL filtrate to 250 mL beaker and evap. to 20–30 mL to remove alcohol. Cool, and wash with  $\text{H}_2\text{O}$  into 100 mL vol. flask, holding vol. to 80–90 mL. Add dry powd *phosphotungstic acid* in small amts in slight excess to ppt any protein, mix, let stand few min for gas bubbles to rise to surface, dil. to vol. with  $\text{H}_2\text{O}$ , mix, and filter. To filtrate add, in very small portions, enough dry powd KCl to ppt any excess phosphotungstic acid, filter if necessary, and test filtrate for complete pptn.

To correct for error due to vol. occupied by ppt in samples contg added sucrose, repeat detn, weighing same amt of sample into 500 mL vol. flask contg 1 g  $\text{CaCO}_3$  and 100 mL 5% NaCl soln. Add 260 mL alcohol with continuous mixing. Let stand few min for gas bubbles to rise to surface, cool to room temp., dil. to vol. with  $\text{H}_2\text{O}$ , mix, and filter thru 18.5 cm folded paper. Transfer 300 mL filtrate to 400 mL beaker, evap. to 20–30 mL, and proceed as above. To obtain amt of sucrose, subtract % sucrose obtained in 250 mL diln detn from twice the % obtained in 500 mL diln detn.

(b) *Dried eggs*.—From well mixed sample, **17.001(c)**, transfer 2.5 g whites or 10 g yolks or whole eggs to 250 mL vol. flask contg 1 g  $\text{CaCO}_3$  and 50 mL 5% NaCl soln, and let stand 1 hr, mixing every 5 min. Add 130 mL alcohol with continuous mixing, and proceed as in (a), beginning with third sentence.

#### 17.029

#### Determination

(a) *Reducing sugars direct*.—Transfer 25 mL prepd filtrate to 400 mL beaker, and proceed as in **31.038**. Report as % glucose.

(b) *Reducing sugars invert*.—Transfer 50 mL prepd filtrate to 100 mL vol. flask, and invert sucrose as in **31.026(b)** or (c). Neutze with NaOH soln, cool to room temp., and dil. to vol. with  $\text{H}_2\text{O}$ . Transfer  $\leq 50$  mL to 400 mL beaker, and proceed as in **31.038**. Deduct % invert sugar obtained before inversion from that obtained after inversion, multiply difference by 0.95, and report as % sucrose.

### Glycerol (13)

#### Qualitative Test—Procedure

#### 17.030

#### Reagent

*Fuchsin-bisulfite soln*.—Dissolve 0.2 g basic fuchsin in 120 mL hot  $\text{H}_2\text{O}$  and cool; add soln of 2 g anhyd.  $\text{Na}_2\text{SO}_3$  in 20 mL  $\text{H}_2\text{O}$ , and then 2 mL HCl. Dil. soln with  $\text{H}_2\text{O}$  to 200 mL and let stand 1 hr.

## 17.031

**Detection**

Add 20 mL alcohol to ca 5 g sample in erlenmeyer or beaker-flask, shake vigorously, and filter thru 12.5 cm fluted paper. Evap. filtrate rapidly until no odor of alcohol is perceptible, cool, and add 3–4 drops H<sub>2</sub>O and then 10–15 mL anhyd. ether. Carefully mix solns, let sep., and pour off as much of ether layer as possible, disregarding cloudiness in this layer. Shake well with two 10 mL portions anhyd. ether, pouring off ether carefully in each case. (Vol. aq. soln should be  $\geq 0.4$ –0.5 mL.) Evap. remaining liq. on steam bath to 0.1–0.2 mL. Cool, and add 15 mL mixt. of equal vols absolute alcohol and CHCl<sub>3</sub>. Cool, shake, and let stand 5 min.

Shake, and filter thru fluted paper into 25 × 150 mm Pyrex test tube. Evap. filtrate rapidly (small flame and current of air is convenient) until no odor of CHCl<sub>3</sub> or alcohol is perceptible. Add several g powd KHSO<sub>4</sub> and insert stopper with glass tube leading into 2 mL H<sub>2</sub>O in test tube immersed in ice-H<sub>2</sub>O. Heat with small flame until frothing ceases and contents of tube are liq. Remove receiver, immediately add 4–5 drops of fuchsin-bisulfite soln, and warm to room temp. In presence of glycerol, strong pink (due to acrolein) develops within 1 min and becomes deep violet within 5 min.

**Quantitative Method (14)—Official Final Action**

## 17.032

**Reagents**

(a) *Sodium tungstate soln.*—Dissolve 10 g Na<sub>2</sub>WO<sub>4</sub>·2H<sub>2</sub>O and dil. to 100 mL.

(b) *Potassium periodate soln.*—0.02M. Dissolve 4.6 g KIO<sub>4</sub> in ca 500 mL hot H<sub>2</sub>O, dil. to ca 900 mL with H<sub>2</sub>O, cool to room temp., and dil. to 1 L. Test for alky by adding 0.02N H<sub>2</sub>SO<sub>4</sub> to 25 mL of the soln contg bromocresol purple, (c). Do not use if >1 drop acid is required to give yellow acid color.

(c) *Bromocresol purple indicator.*—Dissolve 0.1 g bromocresol purple in 100 mL alcohol and filter if necessary.

(d) *Calcium oxide, powdered.*—Reagent grade.

## 17.033

**Determination**

(a) *Eggs with no added sugars.*—Accurately weigh, by difference, ca 2 g well mixed sample, 17.001(a) or (b), into 100 mL vol. flask contg 50–75 mL H<sub>2</sub>O. Mix and add 2.0 mL Na<sub>2</sub>WO<sub>4</sub> soln. Slowly add 2.0 mL 1N H<sub>2</sub>SO<sub>4</sub> with continuous mixing. Dil. to vol. with H<sub>2</sub>O, mix well, and filter (18.5 cm folded paper). Transfer aliquot of filtrate contg  $\leq 40$  mg glycerol to 300 mL erlenmeyer, and dil. with H<sub>2</sub>O to 20 mL if necessary. Add 2 mL 10% NaOH soln, heat to bp, and boil 30 sec. Cool slightly, add 3 drops bromocresol purple, neutze with 1N H<sub>2</sub>SO<sub>4</sub> (use buret), and add 1–2 drops excess. Boil 1 min, cool to room temp., and neutze carefully with 0.02N NaOH, titrg to light purple.

Quant. transfer neut. soln to 100 mL vol. flask, restricting total vol. to  $< 50$  mL. (As aid, mark side of flask to indicate vol. of ca 45 mL.) If necessary, add more 0.02N NaOH to maintain light but definite purple. Continue as in 35.081(b), beginning "... add 50 mL KIO<sub>4</sub> soln." and using 35.082(a) for detn.

Excess periodate must be present after oxidn. If periodate test is neg., repeat detn, using smaller aliquots.

(b) *Eggs containing added sugars.*—Prep. sample soln as in (a), using ca 2 g sample.

Transfer aliquot of filtrate contg  $\leq 40$  mg glycerol to 400 mL beaker. Adjust vol. to 20 mL by evapn on steam bath or by addn of H<sub>2</sub>O. Add 0.5 g powd CaO, mix, and let stand 30 min at room temp. with occasional mixing. Add 25 mL alcohol, mix, and filter with suction, using buchner and 7 cm S&S 597 paper, or equiv. Rinse beaker, funnel, and paper with several portions alcohol. Transfer as much residue as possible to paper but do not

attempt to remove film of lime salts adhering to beaker. Quant. transfer filtrate to original 400 mL beaker, rinsing flask with several portions H<sub>2</sub>O. Evap. filtrate on steam bath to ca 10 mL. Filter thru 9 cm S&S 597 paper, or equiv., collecting filtrate in 300 mL erlenmeyer. Rinse beaker, funnel, and paper with small amts of H<sub>2</sub>O, restricting total filtrate to  $\leq 25$  mL. Add 1 mL 10% NaOH soln to filtrate and complete detn as in (a), beginning "... heat to bp, and boil 30 sec."

**Acidity of Ether Extract (15)—Official Final Action**

(Not applicable to egg white)

## 17.034

**Reagents**

(Caution: See 51.038.)

(a) *Benzene.*—Use best quality available. If not neut., titr. 50 mL with 0.05N Na ethylate, (b), and correct subsequent results accordingly.

(b) *Sodium ethylate std soln.*—0.05N. Dissolve piece of metallic Na (Caution: See 51.034), ca 1 mL in vol., in 800 mL absolute alcohol. Titr. 10 mL 0.1N HCl with this soln and add calcd vol. absolute alcohol to make soln 0.05N. Stdze against 0.1N HCl on day soln is used.

## 17.035

**Determination**

(Caution: See 51.011, 51.039, and 51.054.)

(a) *Dried eggs.*—Weigh 2 g dried eggs into small lipped erlenmeyer, add 30 mL ether, and mix well. After ether layer clears, decant thru small filter paper into weighed flask. Repeat extn with three 20 mL portions ether. Evap. ether on steam bath and dry ext 15 min at 100°. Cool, weigh, dissolve in 30 mL benzene, add 3–4 drops phthln, and titr. with NaOEt soln. (End point is reached when yellow changes to orange.) Report as mL 0.05N NaOEt required/g ether ext.

(b) *Liquid eggs.*—Weigh ca 8 g liq. eggs into 9 cm lipped evapg dish, and dry at 55° under pressure  $\leq 125$  mm Hg (16.7 kPa) until eggs are thoroly dry (ca 5 hr). Grind dried eggs in evapg dish with small pestle, and proceed as in (a), beginning "... add 30 mL ether, and mix well."

**Lactic, Succinic, and Beta-Hydroxybutyric Acids (16)  
Official Final Action**

## 17.036

**Reagents**

(a) *Boron trifluoride-1-propanol soln.*—10%. Prep. as follows: In fume hood, assemble following or equiv. gas train. Connect two 500 mL all-glass gas washing bottles (Corning Glass Works No. 1760), with longer arms adjacent, in tandem to BF<sub>3</sub> cylinder (Matheson Gas Products, PO Box E, Lyndhurst, NJ 07071) with short lengths of Teflon tubing. Transfer 250 mL PrOH to end bottle, weigh, and cool in ice bath. Connect bottle in ice bath to gas train and bubble BF<sub>3</sub> slowly into PrOH until 22 g is taken up. (BF<sub>3</sub> must be passing thru glass tube before tube is placed in and until after it is removed from PrOH.) If >22 g BF<sub>3</sub> is added, dil. with PrOH until total mL PrOH is 11.4 × g BF<sub>3</sub>. Store reagent in g-s bottle in refrigerator.

Com. reagent, 14% w/v (Applied Science Laboratories, Inc.), may be used undild or dild 1 vol. + 0.6 vol. PrOH. (Note: Remove BF<sub>3</sub> vapors with effective fume removal device. Avoid contact with skin, eyes, and respiratory tract. See 51.010.)

(b) *Calcium lactate std solns.*—Prep. fresh daily. Dissolve 0.856 g USP Ca lactate·5H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL (Soln A: 5.0 mg lactic acid equiv./mL). Dil. 25, 20, 15, and 5 mL Soln A to 50 mL with H<sub>2</sub>O to prep. solns contg 2.5 (B), 2.0 (C), 1.5 (D), and 0.5 (E) mg lactic acid equiv./mL, resp.

(c) *Succinic acid std solns.*—Prep. fresh daily. Dissolve 1.000

g succinic acid (Fisher Certified, or equiv.) in H<sub>2</sub>O and dil. to 100 mL (Soln F: 10.0 mg/mL). Dil. 25, 25, and 15 mL Soln F to 50, 100, and 100 mL with H<sub>2</sub>O to prep. solns contg 5.0 (G), 2.5 (H), and 1.5 (I) mg/mL, resp.

(d) *Acetophenone (AP) solns.*—(1) Std soln.—Dissolve 0.800 g acetophenone (MC/B Manufacturing Chemists, C-Q AX0164) in PrOH and dil. to 100 mL in vol. flask. Store at room temp. (2) *Diluting soln.*—Prep. fresh daily. Pipet 20 mL PrOH, 10 mL AP std soln 1, and 20 mL CHCl<sub>3</sub> into 125 mL separator. (If CHCl<sub>3</sub> cannot be used in GLC system, ether may be substituted. However, ether solns must be chromatographed ≤24 hr after esterification.) Add 40 mL satd (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> soln, stopper, shake separator ca 1 min, and let layers sep. Drain bottom aq. layer and discard. Transfer upper layer to g-s flask and add 5 g anhyd. Na<sub>2</sub>SO<sub>4</sub>.

(e) *Ether.*—Anhyd., contg ≤0.05% alcohol.

(f) *Sodium beta-hydroxybutyrate std soln.*—Dissolve 0.121 g Na β-hydroxybutyrate (Sigma Chemical Co.) in H<sub>2</sub>O and dil. to 100 mL (1 mg β-hydroxybutyric acid equiv./mL).

### 17.037

### Apparatus

(Caution: See 51.039 and 51.046.)

(a) *Gas chromatograph.*—With flame ionization detector. Operating conditions: 3 m (10') × 4 mm id glass tube packed with 10% stabilized diethyleneglycol succinate (DEGS) on 100–120 mesh Gas-Chrom Z. Temps (°): column 130, injection zone 200, detector 200; He 80 mL/min; H 37 mL/min; air 400 mL/min; electrometer sensitivity  $9 \times 10^{-10}$  amp full scale; 5 mv recorder; chart speed 50 cm (20")/hr.

(b) *GLC column.*—Dissolve 1.2 g stabilized DEGS (Analabs, Inc., No. C6) in 100 mL acetone in 250 mL beaker. Add 10.8 g 100–120 mesh Gas-Chrom Z to DEGS-acetone soln. Evap. acetone on steam bath, stirring occasionally with glass rod, and complete evapn in 50–60° vac. oven 1 hr. Rinse GLC tube with acetone and dry with vac. line. Fill tube with 5% soln of dimethyldichlorosilane in toluene and let stand ca 5 min. Rinse tube with MeOH until washings are neut. to litmus (ca 300 mL) and dry with vac. line. Pack tube with coated support and condition 48 hr at 200° with N flow of ca 30 mL/min. Do not pack inlet portion of column that may be exposed to flash heater. (Any column giving equiv. sepn of Pr esters may be used.)

(c) *Filtering funnel.*—Glass, short stem, ca 35 mm diam. (Kimble Products No. 28950, or equiv.).

### 17.038

### Calibration

(Caution: See Note, 17.035(a), and 51.018.)

(a) *Lactic and succinic acids.*—See Table 17:01 for std solns to be used for calibration. For each combination, pipet indicated vols Ca lactate and succinic acid std solns into 250 mL  $\frac{24}{40}$  r-b flask and evap. to dryness on steam bath or, more rapidly, in rotary evaporator at 100°. Remove only enough BF<sub>3</sub>-PrOH for one day's use to 25 mL g-s erlenmeyer. Pipet 2 mL BF<sub>3</sub>-PrOH into 250 mL r-b flask, insert short-stem filtering funnel, (c), into neck, and reflux 10 min on steam bath.

Remove from steam bath and let cool to room temp. Add 4 mL satd (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, pipet 1 mL AP std soln and 2 mL CHCl<sub>3</sub> into flask, and swirl to mix. (If CHCl<sub>3</sub> cannot be used in GLC system, ether may be substituted. However, ether solns must be chromatographed ≤24 hr after esterification.) Pour contents of flask into 30 mL separator. Stopper, shake 1 min, and let layers sep. Drain bottom aq. layer and discard. Transfer upper layer to screw-capped glass vial, add ca 3 g anhyd. Na<sub>2</sub>SO<sub>4</sub>, cover with Al foil, seal with cap, and shake briefly. Store in refrigerator if soln is to be used after day of prepn.

**Table 17:01 Standard Solutions for Calibration of Gas Chromatograph**

Combination	Calcium Lactate (b) <sup>a</sup>		Std Soln	Succinic Acid (c) <sup>a</sup>		Std Soln
	mg <sup>b</sup>	mL		mg	mL	
1	1	2	E	3	2	I
2	3	2	D	5	2	H
3	4	2	C	7.5	3	H
4	5	2	B	10	2	G
5	6	4	D	15	3	G
6	8	4	C	20	2	F
7	10	2	A	25	5	G
8	12.5	5	B	30	3	F
9	15	3	A	40	4	F

<sup>a</sup> Letters refer to solutions under *Reagents*.

<sup>b</sup> Lactic acid equivalent.

Adjust sensitivity and attenuation of gas chromatograph to fit range of stds without addnl diln. (With gas chromatograph so adjusted, ht of internal std (AP) peak is ca  $\frac{1}{3}$  full scale.) Use same attenuation and sensitivity settings for calibration stds and sample solns.

When withdrawing soln for GLC, insert syringe needle thru Al foil. Make duplicate injections of  $3 \pm 0.2$   $\mu$ L clear soln into gas chromatograph. For each run, measure peak hts and calc. peak ht ratio, *r*, for each acid. Make calibration charts by plotting values of *r* against *W*. For each acid, *r* = ht of acid ester peak/ht of internal std (AP) peak and *W* = total mg acid esterified with PrOH.

When solv. peak tails into region of Pr lactate peak, extend tail of solv. peak as if no other peak were present. Use this extension as baseline for measuring ht of Pr lactate peak.

(b) *Beta-hydroxybutyric acid.*—Pipet 1, 5, 10, and 15 mL Na β-hydroxybutyrate std soln into sep. 250 mL  $\frac{24}{40}$  r-b flasks and evap. to dryness in rotary evaporator at 50° and <4 kPa (30 mm Hg) pressure. Proceed as in (a).

### 17.039

### Determination

(Caution: See 51.011, 51.018, 51.039, and 51.054.)

Use reagent grade anhyd. ether contg ≤0.05% alcohol. Otherwise, results may be low due to formation of Et lactate, di-Et succinate, and Et Pr succinate with retention times, relative to AP, of ca 0.27, 1.02, and 1.38, resp.

Prep. sample soln and ext acids with anhyd. ether in continuous extractor as in 17.048(a), 17.050, and 17.051. In 17.050, note that sample is made to 1 kg (by wt) before filtering; 24 cm fluted S&S 588 filter paper is satisfactory for filtration. Cover funnel and receiver with Al foil during filtration to prevent evapn. Gently evap. aliquot filtrate (usually 500 mL) to ca 100 mL on hot plate and then to ca 25 mL on steam bath. In 17.051, make calibration mark on extractor at 40 mL. Use 250 mL  $\frac{24}{40}$  r-b extn flask. Add few SiC chips. Ext as long as necessary for complete extn, making sure that all ether from condenser returns to inner tube of extractor. (Det. time necessary for complete extn as follows: Ext mixt. of 0.342 g Ca lactate.5H<sub>2</sub>O (equiv. to 0.200 g lactic acid), 0.5 mL 18N H<sub>2</sub>SO<sub>4</sub>, 15 g (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, and 40 mL H<sub>2</sub>O for time required for min. 98% recovery (ca 3–5 hr). Add 20 mL H<sub>2</sub>O to flask and expel ether on steam bath. Do not let flask remain on steam bath after ether is expelled. Det. recovery by titrn with std alkali (1 mL 0.1N NaOH = 9.008 mg lactic acid).)

Do not add 5 mL H<sub>2</sub>O to ether ext as specified in 17.051, par. 3. Evap. ether with rotary evaporator at 30° to ≤1 mL, but not to dryness. Pipet 2 mL BF<sub>3</sub>-PrOH reagent into flask and continue as in 17.038.

(Note: It is necessary to pipet 2 mL  $\text{BF}_3\text{-PrOH}$  into flask within few min after removing ether because of tendency for polymerization between org. acids when  $\beta$ -hydroxybutyric acid is present. After adding  $\text{BF}_3\text{-PrOH}$  reagent, heating can be delayed until remaining samples are ready for esterification (applies when several extractors are operated simultaneously). Flasks should be stoppered during interval. If ether extns are completed near end of working day, do *not* evap. ether. Flasks contg ether exts should be left attached to extg tubes. Ether exts can then be left at room temp. overnight and ether removed next day just before esterification. (Caution: Use effective fume removal devices to prevent hazardous accumulation of flammable vapors.))

Measure peak hts and calc.  $r$  for each acid. Det.  $W$  from calibration chart. Make duplicate GLC analyses and calc. av. wt of acid,  $W$ .

If acid concns give responses greater than full scale, pipet 1 mL sample soln and  $\geq 1$  mL AP dilg soln into screw-capped glass vial, add ca 0.2 g anhyd.  $\text{Na}_2\text{SO}_4$ , cover with Al foil, seal with cap, and shake briefly. Record vols of sample and dilg solns used. Make duplicate injections of  $3 \pm 0.2$   $\mu\text{L}$  dild soln into gas chromatograph. Store in refrigerator if soln is to be used after day of prepn.

If further dilns are required, pipet addnl AP dilg soln into dild sample soln and mix. Alternatively, pipet greater vol. of AP dilg soln into 1.0 mL undild sample soln, mix, and make duplicate injections of  $3 \pm 0.2$   $\mu\text{L}$  into gas chromatograph.

For each acid, use max. peak ht (min. diln factor) consistent with range and response limitations of recording device used. (For example, if only lactic acid is concd enough to require diln, calc. lactic acid from chromatogram of dild soln and other acids from chromatogram of undild soln.) Multiply result by diln factor ( $F$ ):  $F = \text{vol. after diln} / \text{vol. before diln}$ . For confirmatory test for succinic acid, see 17.053.

#### Lactic Acid (17)—Official Final Action

##### Colorimetric Method

(If succinic acid is also to be detd, proceed as in 17.048–17.053.)

##### 17.040

##### Preparation of Solution

(a) *Liquid or frozen eggs*.—Transfer 40 g sample to weighed 300 mL erlenmeyer, add ca 75 mL  $\text{H}_2\text{O}$ , and shake thoroly. Add 15 mL 1N  $\text{H}_2\text{SO}_4$  and 25 mL 20% *phosphotungstic acid soln*, dil. to 200 g with  $\text{H}_2\text{O}$ , shake ca 1 min, and filter thru folded paper.

(b) *Dried eggs*.—Mix 10 g sample and 100 mL  $\text{H}_2\text{O}$  into paste with stirring rod and add, with const stirring, 10 mL 1N  $\text{H}_2\text{SO}_4$ , followed by 15 mL 20% *phosphotungstic acid soln*. Transfer mixt. with  $\text{H}_2\text{O}$  to weighed 300 mL erlenmeyer, dil. to 200 g with  $\text{H}_2\text{O}$ , shake ca 1 min, and filter thru folded paper.

Weigh 100 g filtrate obtained as in (a) or (b) into 250 mL beaker and evap. to ca 25 mL. Transfer material to liq. extractor with 25 mL  $\text{H}_2\text{O}$  and proceed as in 16.030–16.031. Report lactic acid in terms of mg/100 g, making no correction for insol. solids in portion taken for analysis.

#### Volatile Fatty Acids (18)—Official Final Action

##### Column Chromatographic Method

##### 17.041

##### Preparation of Solution

(a) *Liquid or frozen eggs*.—Weigh 80 g sample, 17.001(a) or (b), into weighed 500 mL erlenmeyer, add ca 150 mL  $\text{H}_2\text{O}$ , and shake vigorously.

(b) *Dried eggs*.—Weigh 25 g sample, 17.001(c), into 250 mL beaker, and with heavy stirring rod make into smooth paste

with  $\text{H}_2\text{O}$ . Transfer mixt. to weighed 500 mL erlenmeyer, using ca 200 mL  $\text{H}_2\text{O}$ .

Add 25 mL 1N  $\text{H}_2\text{SO}_4$  to mixt. obtained as in (a) or (b) and shake ca 1 min. Add 20% *phosphotungstic acid soln* (40 mL usually enough to give clear filtrate), dil. to 350 g with  $\text{H}_2\text{O}$ , and shake 1 min. Filter thru 24 cm folded paper.

##### 17.042

##### Determination

Pipet 150 mL filtrate, 17.041 (equiv. to 150 g; sp gr is ca 1.00), into distn flask of app. (Fig. 18.02) and proceed as in 18.054–18.058.

Fraction of each acid recovered in first 200 mL distillate is: Formic 0.405, acetic 0.57, propionic 0.81, and butyric 0.92; fraction of formic acid recovered in second 200 mL distillate is 0.24. To calc. mg of each acid in wt of sample used for distn, divide mg detd in distillate by fraction recovered. For liq. or frozen eggs, multiply by 2.92 and for dried eggs by 9.34 to obtain mg acid/100 g sample.

#### Gas Chromatographic Method (19)

##### Official Final Action

##### 17.043

##### Reagents

(a) *Acetone*.—Redistd.

(b) *Dichloroacetic acid (DCA) soln*.—0.5N. Redistil DCA, weigh 0.645 g into 10 mL vol. flask, and dil. to vol. with acetone. Prep. daily.

(c) *Methyl heptyl ketone (MHK) solns*.—(1) *Std soln*.—Dil. 280 mg MHK to 200 mL with acetone. (Concn may be adjusted, if required by sensitivity of gas chromatograph, provided that same concn is used for calibration and detn.) (2) *Diluting soln*.—Dil. 1 vol. std soln with 3 vols acetone.

(d) *Std acid solns*.—Check purity of formic, acetic, propionic, and butyric acid reagents initially by gas chromatgy. Prep. std soln of each acid by dissolving ca 0.834 g in acetone and dilg to 100 mL. Pipet 10 mL soln into erlenmeyer, add 10 mL  $\text{H}_2\text{O}$  and 2 drops phthln and det. acid content by titrg with 0.1N NaOH.

mg Acid/mL std soln = mL 0.1N NaOH  $\times$  normality  $\times F$ , where  $F = 4.60$  for formic; 6.01 for acetic; 7.41 for propionic; and 8.81 for butyric acid.

##### 17.044

##### Apparatus

(Gas chromatgc equipment, column packings, and operating conditions other than those described below may be used if they provide at least equiv. peak sepn (JAOAC 46, 486(1963)).)

(a) *Distillation apparatus*.—Stdze distn app. (Fig. 18.02) as in 18.052.

(b) *Gas chromatograph*.—Use gas chromatograph equipped with all-glass injection and column system. If  $\text{HCOOH}$  is among acids to be detd, use Ar ionization detection; otherwise, flame ionization detector can be used.

Typical operating conditions: temps ( $^{\circ}$ )—injection zone 200, detector 170, and column 100; Ar flow 50 mL/min, and 1.8 m (6') glass column. He may be used as carrier gas with flame ionization detector.

(c) *Preparation of column packing*.—Weigh 1.3 g ethylene glycol adipate (Applied Science Laboratories, Inc.) into 150 mL beaker and dissolve by stirring in 70 mL acetone. Weigh 0.26 g 85%  $\text{H}_3\text{PO}_4$  into second beaker and dissolve in 30 mL acetone. Combine both solns. Weigh 12.5 g Anakrom ABS, 110–120 mesh (Analabs, Inc.), into 500 mL r-b flask, add combined acetone solns, and evap. in rotating evaporator at reduced pressure in  $\text{H}_2\text{O}$  bath at  $35^{\circ}$  (enough to pack one 1.8 m (6') column).

Pack column evenly. Condition in column oven  $>12$  hr at  $150^{\circ}$

by passing Ar or N thru column at ca 20 mL/min. Direct effluent thru  $\frac{1}{16}$ " (1.6 mm) stainless steel tubing into small test tube shielded from heat of oven. Column is ready for use when bleeding of column substrate into test tube over 2 hr period has practically stopped.

**17.045****Calibration**

Prep. std acid mixts as follows: Pipet 20 mL each std acid soln into same 100 mL vol. flask, dil. to vol. with acetone, and mix (*Soln 1*: ca 5 mg each acid/3 mL). Dil. 15, 10, and 5 mL *Soln 1* to 25 mL, and dil. 5 and 1 mL *Soln 1* to 50 mL with acetone to prep. solns contg ca 3, 2, 1, 0.5 and 0.1 mg each acid/3 mL, resp. Pipet 3 mL each std acid mixt. into glass vial, add 1.0 mL MHK internal std, seal tightly with Sn foil- or Teflon-lined screw cap, and mix.

Adjust sensitivity and attenuation of gas chromatograph to fit range of stds without addnl diln. Use same instrument settings for calibration stds and sample solns. Make duplicate injections of  $2 \pm 0.2 \mu\text{L}$  soln into gas chromatograph. Use smaller vol. (e.g.,  $1.5 \mu\text{L}$ ) if necessary to keep stds on scale. Make calibration chart for each acid by plotting  $r$  against  $W$  ( $r$  = ht of acid peak/ht of internal std peak and  $W$  = mg acid in total vol. of acetone soln, 4 mL). Store solns in refrigerator if they are to be used after day of prepn.

When solv. peak tailing extends into other peaks, draw tail of solv. peak as it would normally appear if no other peaks were present. Use this curved extension as baseline for measuring hts of all peaks above it. Measure hts of remaining peaks to normal baseline.

**17.046****Preparation of Solution**

(If less than specified sample is available, adjust all wts and vols proportionally.)

(a) *For volatile acids only.*—(1) *Liquid or frozen eggs.*—Weigh 80 g sample, **17.001(a)** or (b), into weighed 500 mL erlenmeyer, add ca 150 mL  $\text{H}_2\text{O}$ , and shake vigorously. (2) *Dried eggs.*—Weigh 25 g sample, **17.001(c)**, into 250 mL beaker and, with heavy stirring rod, make into smooth paste with  $\text{H}_2\text{O}$ . Transfer mixt. to weighed 500 mL erlenmeyer, using ca 200 mL  $\text{H}_2\text{O}$ .

Add 25 mL 1*N*  $\text{H}_2\text{SO}_4$  to mixt. obtained as in (1) or (2) and shake ca 1 min. Add 20% phosphotungstic acid soln (40 mL usually enough to give clear filtrate), dil. to 350 g with  $\text{H}_2\text{O}$ , and shake 1 min. Centrf. in 250 mL bottles 10 min at 2000 rpm and filter (24 cm fluted S&S 588 paper is satisfactory).

(b) *For volatile acids and succinic or other nonvolatile acids.*—(1) *Liquid or frozen eggs.*—Weigh 200 g sample into 1 L erlenmeyer, add 500 mL  $\text{H}_2\text{O}$ , and mix well, avoiding violent shaking; add 75 mL 1*N*  $\text{H}_2\text{SO}_4$  and mix well. Add 125 mL 20% phosphotungstic acid soln, dil. to 1 kg with  $\text{H}_2\text{O}$ , and shake 1 min. Centrf. in 250 mL bottles 10 min at 2000 rpm and filter (24 cm fluted S&S 588 paper is satisfactory). Pipet 150 mL into distg flask and proceed as in **17.047**. Record vol. of remaining filtrate and use for detn of nonvolatile acids, **17.039**.

(2) *Dried eggs.*—Weigh 50 g sample into 400 mL beaker and, with heavy stirring rod, make into smooth paste with  $\text{H}_2\text{O}$ . Transfer to 1 L erlenmeyer and add enough  $\text{H}_2\text{O}$  to make total wt of 700 g. Add 50 mL 1*N*  $\text{H}_2\text{SO}_4$  and mix well. Add 75 mL 20% phosphotungstic acid soln and proceed as in (1), beginning "... dil. to 1 kg with  $\text{H}_2\text{O}$ , ..."

**17.047****Determination**

Pipet 150 mL filtrate, **17.046** (sp gr is ca 1.00), into distn flask of app. (Fig. **18:02**). Make acid to Congo red paper with  $\text{H}_2\text{SO}_4$  (1+1). Steam distil as in **18.052**. Collect 200 mL distillate, transfer

distillate to 500 mL  $\frac{1}{2}$  24/40 r-b flask, and quant. neutze with 0.01*N* NaOH, using phthln. Add 1 mL 0.1*N* NaOH excess. If color is discharged, repeat addn. Conc. to 5–10 mL on rotary evaporator at 50–60°. If color is discharged, add 0.5 mL more 0.1*N* NaOH. Transfer to 50 mL  $\frac{1}{2}$  24/40 r-b flask and evap. to dryness on rotary evaporator at 50–60°. Prevent bumping by degassing with vac. before applying heat.

Alternatively, transfer steam distillate to 600 mL beaker, neutze with 0.01*N* NaOH, add 1 mL 0.1*N* NaOH as above, and conc. to ca 50 mL on steam bath under air stream. Transfer to 150 mL beaker, and conc. to 5–10 mL on steam bath in air stream. Transfer to 50 mL  $\frac{1}{2}$  24/40 r-b flask, and evap. to dryness on steam bath in air stream.

Add vol. 0.5*N* DCA equiv. to total NaOH added and slight excess. Red due to phthln disappears before acids are completely liberated. Add DCA soln until irregular, coarse particles of salts of volatile acids are completely replaced by fine flocculent Na dichloroacetate.

Add 1.0 mL MHK internal std soln and acetone to total vol. of 4.0 mL. (It is necessary to make total 4.0 mL only if dilns are required, as described in following par., when acid concns give greater than full scale response.) Stopper with  $\frac{1}{2}$  24/40 stopper and mix thoroly with vortex-type test tube mixer. If vortex mixer is not available, scrape walls of r-b flask with spatula and crush crystals. Stopper and shake thoroly. Mix or shake again after 5–10 min. Decant soln into Sn foil- or Teflon-lined screw-cap vial and seal tightly.

Inject  $2 \pm 0.2 \mu\text{L}$  into gas chromatograph, or smaller vol. if such was used in calibration. If acid concns give greater than full scale response, dil. 1.0 mL soln with  $\geq 1$  mL MHK dilg soln in screw-cap vial. Record vols of sample and dilg solns used. If further dilns are required, pipet addnl MHK dilg soln into dild sample soln and mix. For each acid, use max. peak ht (min. diln factor) consistent with range and response limitations of recording device. (For example, if only HOAc is concd enough to require diln, calc. HOAc from chromatogram of dild soln and other acids from chromatogram of undild soln.) Det. mg each acid from calibration chart and multiply by diln factor,  $F$  = vol. after diln/vol. before diln. Make duplicate GLC detns and calc. av. wt of acid,  $W$ . Store solns in refrigerator if they are to be used after day of prepn. Run blank detn on 200 mL distillate obtained by steam distg 150 mL soln contg vols 1*N*  $\text{H}_2\text{SO}_4$  and 20% phosphotungstic acid = (vol. each reagent used in **17.046**  $\times$  150)/(total wt sample mixt. before filtration (**17.046**) – wt solids in sample).

To calc. mg of each acid in wt sample used for distn, divide mg detd in distillate by fraction recovered in distn. Typical recoveries for first 200 mL distillate are: Formic acid 0.405, acetic acid 0.57, propionic acid 0.81, and butyric acid 0.92. To obtain mg acid/100 g sample, multiply result by appropriate factor. Factors for solns prepd by **17.046(a)**: 2.92 for liq. or frozen eggs, 9.34 for dried eggs; for solutions prepd by **17.046(b)**: 3.33 for liq. or frozen eggs, 13.33 for dried eggs. For confirmatory tests, see **14.098**, last par.

**Succinic Acid (20)—Official Final Action****17.048****Apparatus**

(a) *Continuous extractor.*—See Fig. **16:01**.

(b) *Chromatographic tube.*—Approx. 17 mm od  $\times$  250 mm, plugged at constricted end with either cotton or glass wool.

**17.049****Reagents**

(a) *Solvent.*—*Tert*-BuOH- $\text{CHCl}_3$  (1+4). Store over granular anhyd.  $\text{Na}_2\text{SO}_4$ .

(b) *Glycerol indicator soln.*—Dissolve 75 mg mono  $\text{NH}_4$  salt

of 3-(4-anilino-1-naphthylazo)-2,7-naphthalenedisulfonic acid (Alphamine Red R, Eastman Kodak Co. No. 6394) in 50 mL glycerol, warming on steam bath.

(c) *Phenol red indicator*.—Rub 100 mg phenolsulfonphthalein in mortar with 5.7 mL 0.05*N* NaOH until dissolved; then dil. to 100 mL with H<sub>2</sub>O.

**17.050****Preparation of Solution**

(a) *Liquid or frozen eggs*.—Weigh 200 g sample into 1 L erlenmeyer, add 500 mL H<sub>2</sub>O, and mix well, avoiding violent shaking; add 75 mL 1*N* H<sub>2</sub>SO<sub>4</sub> and mix well. Add 125 mL 20% *phosphotungstic acid soln*, dil. to 1 kg with H<sub>2</sub>O, and shake 1 min. Divide between two 24 cm rapid folded filter papers. Transfer 250 mL filtrate to 400 mL beaker, evap. to ca 50 mL, add another 250 mL to same beaker, and evap. to 10 mL. If material starts to bump when vol. becomes low, transfer to steam bath.

If <200 g sample is available, take 100 g sample and half quantities of reagents, and dil. to 500 g with H<sub>2</sub>O. Filter ppt on buchner with suction, collecting as much filtrate as possible. Use total weighed filtrate for evapn.

(b) *Dried eggs*.—Weigh 50 g sample into 400 mL beaker, and with heavy stirring rod make into smooth paste with H<sub>2</sub>O. Transfer to 1 L erlenmeyer and add enough H<sub>2</sub>O to make total wt of 700 g. Add 50 mL 1*N* H<sub>2</sub>SO<sub>4</sub> and mix well. Add 75 mL 20% *phosphotungstic acid soln* and proceed as in (a), beginning "... dil. to 1 kg with H<sub>2</sub>O, ..."

**17.051****Extraction**

(Caution: See 51.011, 51.039, and 51.054.)

Place 15 g (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> in dry extractor. Transfer evapd material, 17.050(a) or (b), to inner tube of extractor by washing thru small funnel with enough H<sub>2</sub>O to make total vol. of 40 mL, add 0.5 mL H<sub>2</sub>SO<sub>4</sub> (1+1), and mix by raising and lowering inner tube. Rinse beaker with 50 mL ether and pour rinsings into inner tube of extractor. Connect efficient condenser to extractor and proceed with extn as in 16.030, placing 150 mL ether in extn flask and extg 3 hr or as long as necessary for complete extn.

(To det. time necessary for complete extn, transfer ca 20 mg *succinic acid*, accurately weighed, to extractor contg 20 g (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, add enough H<sub>2</sub>O to give total vol. of 40 mL, and proceed with extn as above. After 3 hr, add 10 mL H<sub>2</sub>O to extn flask, evap. ether on steam bath, and titr. If recovery is <95%, ext another 20 mg *succinic acid* for longer period and titr. Continue until 95% recovery is obtained, and use this period of extn for detn.)

To flask contg ether ext add 5 mL H<sub>2</sub>O and evap. ether on steam bath. Using graduated 5 mL pipet, neutze contents of flask with satd Ba(OH)<sub>2</sub> soln, using phthln. Adjust vol. to 20 mL with H<sub>2</sub>O, add 90 mL alcohol, heat almost to boiling on steam bath, and cool. Add ca 0.5 g filter-aid and filter with suction thru suitable filter, such as Caldwell crucible covered with thin layer of asbestos overlaid with small amt of filter-aid added from suspension in H<sub>2</sub>O. Rinse flask with 3 portions of alcohol (9+2), transferring each rinsing to crucible and sucking dry before adding another portion. Reserve filtrate for detn of lactic acid, 16.031, beginning line 6, "To expel alcohol, evap ...", using entire filtrate and modifying calcs.

Transfer contents of crucible to 100 mL beaker with 15–20 mL H<sub>2</sub>O, acidify to *Congo red paper* with 1–2 drops H<sub>2</sub>SO<sub>4</sub> (1+1), warm on steam bath, and refilter with suction, rinsing beaker with three 10 mL portions H<sub>2</sub>O, transferring each rinsing to crucible, and sucking dry before adding another. Evap. filtrate to ca 5 mL, neutze with 1*N* NaOH, transfer with H<sub>2</sub>O to 50 mL beaker, and evap. to dryness on steam bath.

**17.052****Preparation of Partition Column**

Place 5 g H<sub>2</sub>SiO<sub>3</sub>, 18.051(g), in glazed porcelain evapg dish and add 0.5 mL freshly prepd glycerol indicator soln. (More soln may be necessary if it has stood several weeks.) Then add max. amt of glycerol (1+1) that gel will hold without becoming sticky (usually 1–3 mL) and 1 drop (ca 0.05 mL) ca 1*N* NH<sub>4</sub>OH. Grind into uniform powder with pestle, make into slurry with ca 30 mL of solv., and transfer to chromatgc tube, which is clamped vertically. Apply 5–10 lb (34.5–68.9 kPa) air pressure to top of tube until solv. just disappears into top of gel; release pressure, add 1 mL CHCl<sub>3</sub> contg ca 5 mg HOAc, and again apply pressure until solv. just disappears into gel. Release pressure, add 5 mL solv., and once more apply pressure just long enough for solv. to disappear into gel. (Pressure should never be left on with no liq. above gel; gel would then dry and crack, becoming useless.)

**17.053****Determination**

To dry residue of Na succinate, 17.051, add 2 mL solv. and 3 drops H<sub>2</sub>SO<sub>4</sub> (1+1), and stir with glass rod until all particles are moistened (material should be acid to Congo red paper). Add anhyd. Na<sub>2</sub>SO<sub>4</sub> in 0.5 g portions until material is dry (not gummy), stir, and decant onto prepd partition column, pouring it slowly down side of tube in order to keep surface of gel level. Apply pressure until solv. just disappears into gel. Again wash beaker with 1 mL solv., pour onto column, and with stirring rod transfer residue in beaker to column. Wash beaker with another 1 mL solv., transfer to column, wash inside of tube with 1 mL solv., and apply pressure until solv. just disappears into gel. Fill tube with solv. and apply pressure. Let HOAc band pass out of tube. When front of succinic acid band reaches constricted portion of tube, start collecting eluate in 50 mL graduate. Continue collecting until band has passed entirely from column or until lower edge of any following band reaches 2–5 mm above narrowest portion of constriction of tube and until enough eluate collects to ensure removal of succinic acid from column. (Light placed adjacent to column, but not so close as to heat it, increases visibility of bands.)

(To ensure complete removal of succinic acid from column when there is no following band, det. total amt of eluate to be collected by prepg soln of known amt of Na succinate, transferring free acid to column, eluting, etc., as above, and titrg 25 mL and successive 10 mL fractions of eluate until last fraction requires <0.2 mL 0.01*N* alkali to neutze. Total amt of eluate required is amt to collect in detn.)

Add 10 mL H<sub>2</sub>O to flask and titr. with 0.01*N* Ba(OH)<sub>2</sub>, using phenol red indicator. As end point approaches, stopper flask and shake vigorously to ext acid completely from solv. phase. Correct titrn for blank detn on equal vol. of eluate from blank column. 1 mL 0.01*N* Ba(OH)<sub>2</sub> = 0.59 mg *succinic acid*. If crystallographic identification of Ba succinate (JAOAC 32, 787(1949)) is not desired, 0.01*N* NaOH may be used for titrn.

**Water-Insoluble Fatty Acids (21)—Official Final Action****17.054****Preparation of Solution**

(a) *Liquid or frozen eggs*.—Weigh 10 g prepd sample, 17.001(a) or (b), into 250 mL centrfr. bottle, add 25 mL H<sub>2</sub>O, and mix. Add 20 mL alcohol, shake vigorously, and add 50 mL ether.

(b) *Dried eggs*.—Weigh 2 g prepd sample, 17.001(c), into 100 mL beaker and stir to uniform paste with small amt H<sub>2</sub>O, using heavy stirring rod. Transfer material to 250 mL centrfr. bottle with total of 25 mL H<sub>2</sub>O, and shake vigorously. Rinse beaker with 25 mL alcohol, transfer rinsings to centrfr. bottle, shake vigorously, and add 50 mL ether.

## 17.055

**Determination**

Proceed as in 16.220.

**Pyoverdine****Fluorometric Method (22)—Official Final Action**

(Protect from daylight and other sources of UV light. Incandescent light and pink fluorescent light may be used. Avoid dissolved metals and contact with rubber.)

## 17.056

**Reagents**

- (a) *Alcohol*.—95% USP, redistd from glass.  
 (b) *Chloride buffer soln.*—pH 1. Dry ca 50 g KCl at 120° overnight. Weigh 37.28 g into 500 mL vol. flask, dissolve in H<sub>2</sub>O, and dil. to vol. Add 50 mL of this 1*N* KCl to 97 mL stdzd 1*N* HCl in 200 mL vol. flask, and dil. to vol. with H<sub>2</sub>O.  
 (c) *Potassium acid phthalate soln.*—0.1*M*. Dry ca 20 g at 120° overnight. Weigh 10.21 g into 500 mL vol. flask, dissolve in H<sub>2</sub>O, and dil. to vol. with H<sub>2</sub>O.  
 (d) *Riboflavin std soln.*—0.50 µg/mL, pH 4. Pipet 5 mL riboflavin intermediate soln, 43.040(a)(2), into 100 mL vol. flask, add 50 mL 0.1*M* K acid phthalate, and dil. to vol. with H<sub>2</sub>O. Prep. weekly and store in refrigerator.

## 17.057

**Determination**

Weigh 50±0.1 g foam-free sample, thawed and warmed to 25° on day of analysis, into dry 250 mL centrf. bottle. Add 154 mL alcohol at ca 25°, using pipets, with continuous stirring. Insert polyethylene stopper and shake ca 50 strokes by hand. Centrf. ca 15 min at ca 1200 rpm. Pipet 100 mL supernate into 250 mL separator, add ca 125 mL CHCl<sub>3</sub>, and shake ca 100 strokes by hand. Freeze by immersing separator to base of stopper 10 min in alcohol-solid CO<sub>2</sub> bath; remove from bath.

As soon as ice crystals in CHCl<sub>3</sub> layer thaw, but while outside of separator is still frosty, drain and discard CHCl<sub>3</sub>. Wash sides of separator with 10 mL CHCl<sub>3</sub>, added from pipet without disturbing aq. layer. Let stand 10 min, and drain and discard CHCl<sub>3</sub>. Pass stream of air into emulsion in separator thru small glass tube until soln clears. Remove tube and rinse with small vol. H<sub>2</sub>O. Pipet 10 mL pH 1 buffer into 50 mL vol. flask, quant. add contents of separator, and dil. to vol. with H<sub>2</sub>O.

Measure fluorescence of test and std solns in photofluorometer, using Corning 5874 as primary filter, and Corning 3486 as secondary filter. Swirl std soln before each reading. Calc. concn of pyoverdine expressed as µg riboflavin/100 g egg =  $2 \times C \times R/S$ , where 2 is derived from concn sample in final ext,  $C$  = concn riboflavin std in µg/100 mL,  $R$  = reading of sample, and  $S$  = reading of std riboflavin soln.

## 17.058 Quaternary Ammonium Compounds (23)

**Official Final Action**

See 20.088(d).

# 18. Fish and Other Marine Products

## 18.001 Net Contents of Frozen Seafoods (1) Procedure

Set scale, **32.050**, on firm support and level. Adjust 0 load indicator or rest point and check sensitivity.

(a) *Glazed seafoods*.—Remove package from low temp. storage, open immediately, and place contents under gentle spray of cold H<sub>2</sub>O. Agitate carefully so product is not broken. Spray until all ice glaze that can be seen or felt is removed. Transfer product to circular No. 8 sieve, 20 cm (8") diam. for ≤0.9 kg (2 lb) and 30 cm (12") for >0.9 kg (2 lb). Without shifting product, incline sieve at angle of 17–20° to facilitate drainage and drain exactly 2 min (stop watch). Immediately transfer product to tared pan (B) and weigh (A). Wt product = A – B.

(b) *Unglazed seafoods*.—See **32.051**.

## 18.002 Fish Content of Frozen Breaded Fish Products (2)—Official Final Action

Weigh each unit while it is hard frozen. Using clip tongs, place each portion or stick individually in H<sub>2</sub>O bath maintained at 17–49°C (63–120°F). Let remain until breading becomes soft (5–110 sec for portions held in storage at –18°C (0°F) and can easily be removed from the still frozen flesh with round tip, 10 cm (4") blade spatula or table knife. *Limit dip time in >100°F H<sub>2</sub>O to 15 sec max.*

(Note: Several preliminary trials may be necessary to det. dip time required for debreading sample units. *For these trials only*, prep. satd soln of CuSO<sub>4</sub>·5H<sub>2</sub>O (450 g (1 lb)/2 L tap H<sub>2</sub>O). Correct dip time is min. time of immersion in CuSO<sub>4</sub> soln required before breading can be easily scraped off, provided that debreaded portions are still solidly frozen, and only slight trace of blue color is visible on surface of debreaded portions. As guide, use lower temps with raw and higher temps with precooked products.)

After immersion, remove portion and blot lightly with double thickness paper towel. Complete this step in ≤7 sec. Scrape and remove breading and batter from flesh with spatula, removing material from narrow sides and ends in initial movements followed by removal from wide flat surfaces. If breading is difficult to remove, redip partially debreaded portion in H<sub>2</sub>O at room temp. (17–30°C; 63–86°F) ca 2 sec. Blot with towel and remove residual batter and breading material. Reweigh debreaded portion and record.

% flesh = (wt debreaded portion × 100)/wt original unit.

## 18.003 Cooking Seafood Products (3)—Procedure

Following procedures are based on heating product to internal temp. ≥70°C (160°F). Cooking times vary according to size of product and equipment used. If detg cooking time, cook extra sample, using temp. measuring device to det. internal temp.

For fish blocks or other unbreaded samples, cut ≥3 portions, each ca 10 × 7.5 × 1.2 cm (4 × 3 × 0.5") from sample.

(a) *Bake procedure*.—Wrap product in Al foil and distribute evenly on flat cookie sheet or shallow flat pan. Heat in ventilated oven, preheated to 204°C (400°F), until internal temp. of product reaches ≥70°C (160°F).

(b) *Boil-in-bag procedure*.—Place thawed, unseasoned product in boilable film-type pouch. Fold open end of pouch over suspension bar. Clamp to provide loose seal to let vapors escape during heating. Immerse pouch and contents in boiling H<sub>2</sub>O and heat until internal temp. of product reaches ≥70°C (160°F).

(c) *Deep fat frying procedure*.—Place frozen, breaded product in wire mesh fry basket large enough to hold all items in single layer. Heat by immersing in 190°C (375°F) liq. or hydrogenated cooking oil 2–3 min or until items float to surface. After cooking, let items drain 15 sec and place on paper napkin or towel to absorb excess oil.

(d) *Steam procedure*.—Wrap product in Al foil and place on wire rack suspended over boiling H<sub>2</sub>O in covered container. Heat until internal temp. of product reaches ≥70°C (160°F).

## Detection of Frozen and Thawed Shucked Oysters (4) Official Final Action

### 18.004

### Principle

Latent forms of malic enzyme (ME) activity, solubilized by freezing and thawing, are differentiated from normally sol. form by their differing rates of electrophoretic migration. Medium used to develop sites of ME activity on gels is derived from reaction mixt. used for spectrophotric assay of nicotinamide adenine dinucleotide phosphate (NADP) reduction by ME, together with tetrazolium dye and adjuvant. Sharply discontinuous (disc) buffer system during polyacrylamide gel electrophoresis and carefully timed incubation period for histochem. staining are essential. Gels and solns must be kept cold during electrophoresis. Full work-day is required for test. Do *not* use com. prepd gel solns; pH control is critical. All glassware must be meticulously cleaned, with final soak ≥6 hr in H<sub>2</sub>O before rinsing and drying. Give glass columns final rinse with Kodak Photo-Flo soln (1+200) to ease removal of electrophoresed gels.

### 18.005

### Apparatus

(a) *Articles used in making gel columns*.—(1) *Glass columns*.—62 mm long × 5 mm id soft glass tubing, with unpolished ends. (2) *Disposable syringes*.—5 mL without needle (Gaspak Discardit No. 705 S, Becton, Dickinson, and Co., or equiv.), used with 0.76 mm id, 1.22 mm od polypropylene tubing (Adams Intramedic PE No. 60, Clay-Adams, Inc., Webro Rd, Parsippany, NJ 07054), for loading gels. (Syringes may be washed and reused.) (3) *Water-layer applicator*.—2 mL syringe, without plunger, used with 25 gage 1" hypodermic needle bent slightly for ease of application. (4) *Disposable syringes*.—2.5 mL, with needle (Plastipak Discardit), for removing unpolymerized gel solns during rinse. (5) *Removing tool*.—Grind off flanges of 1 mL glass syringe; no plunger. Attach 22 gage 2" hypodermic needle to one end and short length of rubber tubing to other. Keep another short length of rubber tubing attached to faucet adapter; add ½ plastic tubing-connector to each piece of rubber tubing so that removing tool can be easily attached.

(b) *Apparatus for photopolymerization of gels*.—Convenient set-up for photopolymerizing large pore gels is open-ended wooden box with removable bottom panel. Glue row of small rubber-base caps to bottom panel; (use those supplied with app. or obtain rubber cushions for file tray feet from office supply house). Mount fluorescent light beneath top of box, positioned so that row of rubber caps will be directly under light when bottom panel is in place. Tops of glass columns, placed in rubber caps, should be ca 2.5 cm from light.

(c) *Electrophoresis apparatus*.—Disc electrophoresis bath assembly (Canalco models 12, 1200, or 1200L, Miles Laboratories) with regulated power source capable of maintaining *const* current over 0–50 milliamp range.

**18.006 Preparation of Electrophoretic Reagents**

(a) *Running gel*.—(Small pore, chem. polymerized.) (1) *Soln A*.—Prep. by mixing equal vols *Solns A-1* and *A-2*. (2) *Soln A-1*.—Mix 91.5 g Tris (tris(hydroxymethyl) aminomethane), 0.575 mL TEMED (*N,N,N',N'*-tetramethylethylenediamine, Eastman Kodak Co. No. 8178, or equiv.), and ca 116 mL 1*N* HCl to pH 9.0, and dil. with H<sub>2</sub>O to 250 mL. (3) *Soln A-2*.—Dissolve 70.0 g acrylamide (Eastman Kodak Co. No. X5521, or equiv.) and 1.8375 g BIS (*N,N'*-methylenebisacrylamide, Eastman Kodak Co. No. 8383, or equiv.) in H<sub>2</sub>O and dil. to 250 mL. (4) *Soln B*.—0.14% NH<sub>4</sub> persulfate in H<sub>2</sub>O. (Caution: Acrylamide monomers are neurotoxins. Wear impervious gloves, avoid pipetting solns by mouth, and when dry, handle only in effective fume removal device. Close medical supervision is advisable for persons exposed to this material.)

*Solns A-1* and *A-2* are stable ca 6 months stored in brown bottles in refrigerator; *Solns A* and *B*, only 1 week in refrigerator. Prep. running gel by mixing equal vols *Solns A* and *B* just before use.

(b) *Stacker and sample gels*.—(Large pore, photopolymerized.) (1) *Soln C*.—Prep. by mixing *Solns C-1*, *C-2*, and *C-3* (1+2+1). (2) *Soln C-1*.—Mix 14.95 g Tris, 1.15 mL TEMED, and ca 120 mL 1*N* HCl to pH 5.1, and dil. with H<sub>2</sub>O to 250 mL. (3) *Soln C-2*.—Dissolve 50.0 g acrylamide and 12.5 g BIS in H<sub>2</sub>O and dil. to 500 mL. (4) *Soln C-3*.—4.0 mg riboflavin in 100 mL H<sub>2</sub>O. (5) *Soln D*.—40% (w/v) sucrose in H<sub>2</sub>O.

All solns are stable ca 6 months stored in brown bottles in refrigerator. Prep. stacker gel by mixing equal vols *Solns C* and *D* within 1 hr of use; store at room temp. away from light. Prep. sample gels by mixing 0.04 mL centrfgd tissue fluid with 1 mL stacker gel just before use.

(c) *Electrode buffer (10X)*.—Dissolve 57.6 g glycine and 12.0 g Tris in H<sub>2</sub>O and dil. to 2 L. Dil. 1+9 just before each run; pH should be 8.3. Add few drops ca 0.1% bromophenol blue aq. soln to cathode buffer to light blue tint. Discard both cathode and anode buffers after each run.

**18.007 Preparation of Histochemical Reagent**

For incubating 12 columns, prep. mixt. of 20.0 mg NADP (nicotinamide adenine dinucleotide phosphate, ICN-Pharmaceuticals, Life Sciences Group), 15.0 mL 0.144*M* Tris buffer (17.44 g/L; store in refrigerator; pH 8.0), 9.0 mL 0.095*M* K malate (127 mg L-malic acid neutzd with KOH and dild to 10 mL), 2.4 mL 0.06*M* KCN (dissolve 0.40 g in H<sub>2</sub>O, add 1*N* HCl to pH 8.0 (ca 6 mL) in hood, and dil. to 100 mL; refrigerate in g-s erlenmeyer) (to block electron flux to respiratory chain), and ca 1.0 g polyvinylpyrrolidone (type K30 (MW 40,000), GAF Corp.) (to help solubilize dye). Mixt. may be prepd several hr in advance and stored in refrigerator. Also prep. control medium with H<sub>2</sub>O replacing K malate, if considered necessary.

Prep. 2.4 mg phenazine methosulfate/mL H<sub>2</sub>O. This soln is stable several weeks in refrigerator in dark.

Within hr of use, prep. soln of 15.4 mg *p*-nitro blue tetrazolium chloride (NBT.Cl) in 7.0 mL 0.144*M* Tris buffer (1.74 g/100 mL). (Double amt if using control medium.)

Immediately before incubation of gels, add 0.4 mL phenazine methosulfate soln and the 7.0 mL NTB.Cl soln to main soln.

**18.008 Preparation of Centrifuged Tissue Fluid**

Centrifuge 4 or 5 whole oyster meat samples 20 min at 20,000*g* in refrigerated centrifuge. (Never use minced or homogenized samples. Mech. disruption of tissue produces results similar to freezing.) Withdraw clear supernatant fluid (CTF) with disposable syringe and refrigerate until ready to prep. sample gels. Begin

centrfg early in morning, before setting up running gel, so that CTF will be ready in ample time.

**18.009****Electrophoresis**

(a) *Preparation of gel columns*.—Remove solns for prepg gels from refrigerator and warm slightly to 10–15° (50–60°F). It is not necessary to bring them to room temp., but the colder the solns, the slower the polymerization. Place glass columns in vertical position in small rubber base caps glued to bottom panel of photopolymerization box. (Caution: Protect eyes from direct rays of UV light.) If run is for 12 columns, set up 14 or 15, to have replacements available for any defective columns. Slowly pour equal vols *Soln A* and NH<sub>4</sub> persulfate successively into small beaker and swirl gently (10 mL each is enough for 16 columns). Avoid getting air bubbles in mixt. This running gel will polymerize ca 45 min after mixing.

Using 5 mL disposable syringe, 18.005(a)(2), gently draw up running gel soln; wipe off tip of syringe and insert 7.5–10 cm length of small polypropylene tubing. Push gel soln thru tubing to remove any air; then fill columns to within 15 mm of top, refilling syringe and repeating as needed.

When running gel is in all columns, they must be H<sub>2</sub>O-layered, both to keep gel from contact with air and to establish flat interface between running gel and subsequently added stacker gel. Add drop of 0.1% aq. bromophenol blue tracking dye to small flask of H<sub>2</sub>O, enough to tint H<sub>2</sub>O pale blue. Add ca 2 mL to 2 mL syringe, (a)(3). Perform H<sub>2</sub>O-layering carefully; even small drop falling suddenly can violently disturb ("bomb") gel, and bombed gels must be discarded. Steady each column with one hand, holding H<sub>2</sub>O-layering syringe in other. Wipe tip of needle (finger of hand steadying column is simplest), to keep any sizable drop from forming as it is brought to column. Place needle quickly and gently against inner side of column, sliding it rapidly down to gel surface. If gel is "bombed," remove disturbed gel with disposable syringe, (a)(4), and refill column with fresh running gel mixt.

When H<sub>2</sub>O-layering is completed, set timer for 40 min polymerization period. Mix stacker gel soln at this point, pouring equal vols *Soln C* and 40% sucrose soln carefully into small beaker. Allow 5 or 6 mL for stacker gels and 2 mL each for sample gels. Swirl mixt. and store at room temp. away from light.

When running gels are polymerized, invert columns and gently remove H<sub>2</sub>O layer. Use cotton swabs to draw off any large remaining drops, being careful not to disturb gel surface or to leave fibers on glass. Set columns upright again and add small amt stacker gel to each to rinse out last of H<sub>2</sub>O, using another 5 mL disposable syringe with short length of polypropylene tubing attached. Remove rinse mixt. with disposable syringe, (a)(4). Add stacker gel to each column, to ca 6 mm above running gel surface, and H<sub>2</sub>O-layer as before.

Push columns to within 7.5–10 cm of fluorescent light in box, turn on light, let gels stand 10 min, and then position columns directly under light for final 10 min. Light should be ca 2.5 cm from top of columns. Retrieve CTF from centrfg. and refrigerate during this step.

When stacker gels are photopolymerized, turn off light, remove H<sub>2</sub>O layer from columns as before, and prep. sample gels. Add 0.08 mL CTF of each sample to 2 mL stacker gel in 5 mL beaker, or any amt in proportion. Mix well; add to columns first as rinse, then as 6 mm sample gel, as in stacker gel procedure (use individual 5 mL disposable syringes and tubing), and H<sub>2</sub>O-layer. Photopolymerize as for stacker gels.

(b) *Separation*.—Set up electrophoresis in cold room and chill electrode buffers before use. (Alternatively, place bath assembly

in refrigerator, or circulate ice-H<sub>2</sub>O thru cooling coils immersed in baths.) Prep. histochem. medium during run, reserving tetrazolium dye and adjuvant until just before gel incubation; keep solns refrigerated until use.

As soon as sample gels are polymerized, set up electrophoresis in cold room. Place columns in upper bath container with sample gel on top, toward cathode. (*Caution:* Cover for electrophoresis chamber should have switch to disconnect current to electrodes when chamber is open. Shield contacts and electrodes against body contact.) Add 1 L dild electrode buffer to lower (anode) bath, and bead ends of columns with buffer before setting upper (cathode) bath (from which columns extend) in place above lower bath. Add 1 L dild electrode buffer, tinted pale blue with bromophenol blue, to upper bath, first pipetting small amts into tops of columns, to avoid creating air bubbles. Bromophenol blue migrates more rapidly than proteins, which it will overtake and pass to form visible moving front.

Use const current and do not stop electrophoresis during run. Set at 1 ma/column for first 0.5 hr and then at 2 ma/column for 2 hr. Continue until tracking dye has left columns.

#### 18.010

#### Incubation of Gels

(a) *Removal of gel columns.*—When electrophoresis is finished, remove glass columns from bath assembly, discard buffers, and remove gels from glass columns. Connect rubber tubing on removal tool to suitable faucet adapter and use steady flow of H<sub>2</sub>O while gently reaming gels from glass columns with needle. Loosen anode end of gel column first, then cathode end; gels will slip out easily under H<sub>2</sub>O pressure. Discard sample and stacker gels and place running gels, cathode end up, in 10 × 75 mm test tubes.

(b) *Staining of gels.*—Add histochem. reagent immediately, cork tubes, and invert several times; then place in dark 25–30 min (but not >30 min) at room temp. Rinse gels immediately and thoroly with tap H<sub>2</sub>O; then store in H<sub>2</sub>O. No counterstaining is necessary.

#### 18.011

#### Interpretation

Use densitometer or Polaroid camera for permanent records, as formazan bands on gels will diffuse with time. Unfrozen oysters show, at most, single band, often faint or missing. Frozen and thawed oysters produce broad band at same place with or without 1 or 2 accessory bands and a thin cathodal band.

Freeze and thaw portion of questionable lot and test against portion of original sample. If patterns are alike, lot has been frozen and thawed; if different, lot has not been frozen and thawed.

#### 18.012 Preliminary Treatment and Preparation of Sample (5)—Procedure

To prevent loss of H<sub>2</sub>O during prepn and subsequent handling, use samples as large as practicable. Keep ground material in container with air-tight cover. Begin all detns as soon as practicable. If any delay occurs, chill sample to inhibit decomposition. In general, prep. sample of fish as it is usually prepd by consumer, by including skin and discarding bones, but subject to overall rule of edibility, e.g., inedible catfish skin is discarded; softened canned salmon bones are included; sardines are examined whole. Instructions may be modified in accordance with purpose of specific examination. Prep. samples for analysis as follows:

(a) *Fresh fish.*—Clean, scale, and eviscerate fish. In case of small fish ≤15 cm (6"), use 5–10 fish. In case of large fish, from each of ≥3 fish cut 3 cross-sectional slices 2.5 cm (1") thick, 1

slice from just back of pectoral fins, 1 slice halfway between first slice and vent, and 1 slice just back of vent. Remove bone. For intermediate-size fish, remove and discard heads, scales, tails, fins, guts, and inedible bones; fillet fish to obtain all flesh and skin from head to tail and from top of back to belly on both sides. For detn of fat and fat-sol. components, skin must be included, since many fish store large amts of fat directly beneath skin.

Pass sample rapidly thru meat chopper 3 times. Remove unground material from chopper after each grinding and mix thoroly with ground material. Meat chopper should have holes as small as practicable (1.5–3 mm ( $\frac{1}{16}$ – $\frac{1}{8}$ " diam.) and should not leak around handle end. As alternative for soft fish, high-speed blender may be used. Blend several min, stopping blender frequently to scrape down sides of cup.

(b) *Canned fish, shellfish, and other canned marine products.*—Place entire contents of can (meat and liq.) in blender and blend until homogeneous or grind 3 times thru meat chopper. For large cans, drain meat 2 min on No. 8–12 sieve and collect all liq. Det. wt of meat and vol. of liq. Recombine portion of each in proportionate amts. Blend recombined portions in blender (or grind) until homogeneous.

(c) *Canned marine products packed in oil, sauce, broth, or water.*—Drain 2 min on No. 8 sieve. Prep. solid portion as in (b). Liq. may be analyzed sep., if desired, or reincorporated with solids. H<sub>2</sub>O is usually discarded.

(d) *Fish packed in salt or brine.*—Drain and discard brine and rinse off adhering salt crystals with satd NaCl soln. Drain again 2 min and proceed as in (a).

(e) *Dried smoked or dried salt fish.*—Proceed as in (a).

(f) *Frozen fish.*—Let thaw at room temp., and discard draining. (1) *Fillet.*—Use entire piece. (2) *Whole fish.*—Proceed as in (a).

(g) *Shellfish other than oysters, clams, and scallops.*—If sample is received in shell, wash as in (h) and sep. edible portions in usual way. Prep. edible portion for analysis as in (a).

(h) *Shell oysters, shell clams, and scallops.*—Wash shells in potable H<sub>2</sub>O to remove all loose silt and dirt, and drain well. Shuck enough oysters or clams into clean dry container to yield ≥500 mL (1 pt) drained meats. Transfer shellfish meats to skimmer, 18.014, pick out pieces of shell, drain 2 min on skimmer, and proceed as in (i) or (j).

(i) *Shucked clams or scallops.*—Prep. as in (b).

(j) *Shucked oysters (6).*—Blend meats, including liq., 1–2 min in high-speed blender.

(k) *Breaded fish, raw or cooked.*—Do not remove breading or skin. Proceed as in (a).

#### 18.013 Volume Determination (5)—Official Final Action

(Shucked oysters, clams, or scallops)

Fluff entire contents of com. container, or container in which sample is received (≤3.8 L; 1 gal.), by pouring into std measuring vessel thru distance of ≥30 cm (1'), then pouring back into container from same ht, and again pouring into measuring vessel. Use metal funnel (stainless steel preferable) 20–25 cm (8–10") diam. at top, with stem 7.6 cm (3") diam. and ca 7.6 cm long, to facilitate pouring from one vessel to another. Measures are straight-side, cylindrical, made of metal (stainless steel preferable), holding exactly 1 gal. or 1 qt, resp., and having smooth rims. Plane of rim must be level when measure is standing on level surface. Diam of top of gal. measure is 4.25–5.25", and that of qt measure is 3.25–3.5". Calibrate with std glass measures, and for estg vols less than level full, use graduated mechanic's depth gage to measure distance from rim to surface of contents. Tabulate depth gage readings against vols or % shortages as desired for each measuring vessel.

Measure head space with depth gage and det. vol. For  $\leq 1$  pt containers, calibrated glass cylinders may be used.

#### Drained Liquid (7)—Official Final Action

(Shucked oysters)

##### 18.014

##### Apparatus

*Skimmer or strainer.*—Flat-bottom metal pan or tray with ca 5 cm (2") sides, with area of  $\geq 1900$  cm<sup>2</sup> (300 sq in.) for each gal. of oysters to be poured on tray, and with perforations 0.6 cm (0.25") diam. and 3.2 cm (1.25") apart in sq pattern, or perforations of equiv. area and distribution. Support skimmer over slightly larger solid tray so that liq. drains into solid tray.

##### 18.015

##### Determination

Weigh tared container with shellfish meats, transfer contents to skimmer, and quickly distribute meats evenly over draining surface with min. of handling. Drain 2 min, return meats to container, and reweigh. Calc. loss of wt as % drained liq. Make detns at  $7 \pm 1^\circ$  ( $45 \pm 2^\circ$ F). If further analysis is desired, proceed as in 18.012(j).

#### Drained Weight (8)—Official Final Action

(Applicable to frozen shrimp and Alaska king and snow crabmeat)

##### 18.016

##### Apparatus

(a) *Container.*—Wire mesh basket large enough to hold contents of 1 package and with openings small enough to retain all pieces. Expanded metal test-tube basket or equiv., fully lined with std 16 mesh per linear in. insect screen is satisfactory.

(b) *Balance.*—Sensitive to 0.25 g or 0.01 oz.

(c) *Sieves.*—U.S. No. 8, 20 cm (8") and 30 cm (12") diam.

##### 18.017

##### Determination

Place contents of individual package in wire mesh basket and immerse in  $\geq 15$  L (4 gal.) container of fresh H<sub>2</sub>O at  $26 \pm 3^\circ$ C ( $80 \pm 5^\circ$ F) so that top of basket extends above H<sub>2</sub>O level. Introduce H<sub>2</sub>O of same temp. at bottom of container at flow rate of 4–11 L (1–3 gal.)/min. As soon as product thaws, as detd by loss of rigidity, transfer all material to 30 cm (12") (for package  $> 450$  g (1 lb)) or 20 cm (8") (for package  $\leq 1$  lb) No. 8 sieve, distributing evenly. Without shifting material on sieve, incline sieve to ca  $30^\circ$  from horizontal to facilitate drainage. Two min from time placed on sieve, transfer product to previously weighed pan, and weigh. Wt so found minus wt of pan is drained wt of product.

#### Alaska King Crab Marketing and Control Board Method (9)

(Applicable to Alaska king and snow crabmeat)

##### 18.018

##### Apparatus

(a) *Balance.*—Sensitive to 1 g or 0.01 lb.

(b) *Thermometer.*—Accurate in  $0$ – $30^\circ$ C ( $30$ – $80^\circ$ F) range.

(c) *Plastic bowls.*—Marked at 48 oz (1440 mL), 64 oz (1920 mL), or 1 gal. (3840 mL) level for 6 oz, 8 oz, or 1 lb packages, resp.

##### 18.019

##### Determination

Weigh bare block free of all wrappings and record wt. Place block in bowl contg amt fresh potable water at  $27^\circ$ C ( $80^\circ$ F) equal to  $8 \times$  declared wt. Leave block in H<sub>2</sub>O until all ice is melted. Turn block over several times during thawing. Point at which thawing is complete can be detd by probing block apart.

Pour entire thawed sample onto tared 20 cm (8") No. 8 sieve. Incline screen to aid drainage, drain exactly 2 min, and weigh. Subtract tare wt of sieve for thawed drained wt of sample.

% Drained wt = (thawed drained wt  $\times$  100)/declared net wt.

#### Shrimp in Shrimp Cocktail (10)—Official Final Action

##### 18.020

##### Preparation of Sample

Thaw unopened jars in  $16 \pm 5^\circ$  H<sub>2</sub>O bath until product is defrosted to temp of  $6 \pm 5^\circ$ . Keep jar lids above H<sub>2</sub>O level. Alternatively, place frozen jars in refrigerator until contents have thawed.

##### 18.021

##### Determination

Empty thawed contents of jar onto No. 8 sieve. Wash jar and lid with H<sub>2</sub>O and pour washings onto sieve until jar is clean. Rinse shrimp on sieve with gentle stream or spray of cold tap H<sub>2</sub>O. Use rubber spatula to remove adhering material. Cover sieve with metal cover or moisture barrier film, incline at  $17$ – $20^\circ$  angle, and let drain exactly 2 min. Transfer shrimp to container previously tared with cover and weigh to  $\pm 0.1$  g.

% Shrimp = wt shrimp  $\times$  100/declared wt total contents

#### 18.022 Seafood in Seafood Cocktail other than Shrimp in Shrimp Cocktail (11)—Procedure

(a) *For seafood other than crabmeat.*—Proceed as in 18.020 and 18.021, using rubber spatula gently to remove sauce from irregular surfaces without unduly fragmenting seafood.

(b) *For crabmeat.*—Prep. sample as in 18.020. Empty thawed contents of jar onto No. 8 sieve nested on top of No. 20 sieve. Wash jar and lid with H<sub>2</sub>O until jar is clean and pour washings onto sieves. Rinse crabmeat on No. 8 sieve with gentle stream or spray of cold tap H<sub>2</sub>O. Use rubber spatula to remove adhering material. Cover sieves with metal cover or moisture barrier film, incline at  $17$ – $20^\circ$  angle, and let drain exactly 2 min. Sep. sieves. Invert, dropping No. 8 sieve onto nonabsorbent surface (such as wax paper). Transfer crabmeat to container previously tared with cover. Transfer crabmeat from No. 20 sieve to same container and weigh to  $\pm 0.1$  g.

% Crabmeat = wt crabmeat  $\times$  100/declared wt total contents

#### Total Solids

#### 18.023 For All Marine Products Except Raw Oysters (12) Official Final Action

(Caution: See 51.086.)

Cut into short lengths ca 2 g asbestos fibers of type used in prep gooches. Place cut fibers and glass stirring rod ca 8 cm long with flat end into flat-bottom metal weighing dish, ca 9 cm diam., with cover. Dry dish, asbestos, and rod in oven 1 hr at  $100^\circ$ , cool, and weigh. Quickly weigh into dish, to nearest mg, 9.5–10.5 g prepd sample. Add 20 mL H<sub>2</sub>O and mix sample thoroly with asbestos. Support end of rod on edge of dish and evap. just to dryness on steam bath, stirring once while still moist. Drop rod into dish and heat 4 hr in oven at  $100^\circ$ , or in preheated forced-draft oven set for full draft, 1 hr at  $100^\circ$ . Cover dish, cool in desiccator, and weigh promptly.

#### 18.024 For Raw Oysters Only (13)—Official Final Action

Quickly weigh, to nearest mg, 9.5–10.5 g prepd sample into weighed, flat-bottom metal dish ca 9 cm diam. and 2 cm high with cover. Spread sample evenly over bottom of dish. Then:

(a) Evap. just to dryness on steam bath and dry 3 hr in oven at  $100^\circ$ ; or—

(b) Insert directly into preheated forced-draft oven set at full draft and dry 1.5 hr at 100°.

Cover, cool in desiccator, and weigh promptly.

#### 18.025 Ash (14)—Official Final Action

Dry sample contg ca 2 g dry material and proceed as in 31.012 or 31.013, using temp.  $\leq 550^\circ$ . If material contains large amt of fat, make preliminary ashing at low enough temp. to allow smoking off of fat without burning.

#### 18.026 Total Nitrogen (14)—Official Final Action

See 2.057.

#### Ammonia (15)—Official First Action

(Applicable to crabmeat)

#### 18.027

#### Reagents

(Use  $\text{NH}_3$ -free  $\text{H}_2\text{O}$  thruout; ordinary distd  $\text{H}_2\text{O}$  is suitable.)

(a) *Bromine soln.*—Dil. 10 mL  $\text{NaOH}$  soln (1+1), 50.033(b), to ca 100 mL with  $\text{H}_2\text{O}$ , add 1.0 mL  $\text{Br}$ , shake, and dil. to 200 mL with  $\text{H}_2\text{O}$ . Prep. fresh daily.

(b) *Thymol soln.*—10% in alcohol. Prep. fresh daily.

(c) *Dilute sodium hydroxide soln.*—Dil. 25 mL  $\text{NaOH}$  soln (1+1), 50.033(b), to 100 mL with  $\text{H}_2\text{O}$ .

(d) *Ammonia std soln.*—40  $\mu\text{g/mL}$ . Dissolve 0.314 g  $\text{NH}_4\text{Cl}$ , previously dried 1 hr at 100°, in  $\text{H}_2\text{O}$ , and dil. to 100 mL. Transfer 4.0 mL to 100 mL vol. flask, and dil. to vol. with  $\text{H}_2\text{O}$ .

#### 18.028

#### Preparation of Samples

Remove shell, if necessary, and grind meat 3 times thru food chopper, mixing after each grinding.

#### 18.029

#### Determination

Place 20 g prepd sample in 500 mL g-s erlenmeyer. Add 180 mL 2.5% phosphotungstic acid soln, shake vigorously 2 min, and filter thru Whatman No. 1, or equiv., paper into 250 mL g-s erlenmeyer. Pipet 2 mL filtrate (equiv. to 0.2 g sample) into 125 mL separator. Save remainder of filtrate. To another separator, add 2.0 mL 2.5% phosphotungstic acid soln as blank.

To each separator add 8.0 mL  $\text{H}_2\text{O}$ . Then, in immediate succession, add 1.0 mL dil.  $\text{NaOH}$  soln, (c), swirl to mix, 2.0 mL thymol soln, (b), swirl to mix, and 5.0 mL  $\text{Br}$  soln, (a), in ca 30 small addns, swirling vigorously after each addn. Shake vigorously 1 min. With series of samples or stds, complete reagent addns in sequence on each separator before proceeding to next. Let stand  $\geq 20$  min.

To each separator add 20.0 mL  $n$ -BuOH and shake vigorously 1 min. Let stand 20 min. Drain aq. layer and pass  $n$ -BuOH thru ca 30 g anhyd.  $\text{Na}_2\text{SO}_4$  in glass funnel plugged with glass wool into g-s erlenmeyer. Measure  $A$  of soln at max., ca 680 nm, in 1 cm cell against blank as ref.

If  $A$  is greater than that of highest  $\text{NH}_3$  std, quant. dil. reserved filtrate with 2.5% phosphotungstic acid soln so that 2.0 mL dil soln will produce  $A$  below this level.

#### 18.030

#### Preparation of Standard Curve

Pipet 0, 1, 2, 3, 4, and 5 mL std  $\text{NH}_3$  soln into 125 mL separators. Add 2.0 mL 2.5% phosphotungstic acid soln to each and dil. to 10.0 mL with  $\text{H}_2\text{O}$ . Proceed as in 18.029, beginning "Then, in immediate succession, add 1.0 mL dil.  $\text{NaOH}$  soln, . . ." Using 0 soln as ref., measure  $A$  of each std at max. as above. Prep. std curve.

#### Trimethylamine Nitrogen (16)—Official Final Action

(Do not use stopcock grease; mixt. of sugar and glycerol ground together may be used if necessary. Do not wash tubes with soap or detergent; rinse with  $\text{H}_2\text{O}$  and occasionally clean thoroly with  $\text{HNO}_3$ .)

#### 18.031

#### Reagents

(a) *Trichloroacetic acid soln.*—7.5% aq. soln. (Caution: See 51.082.)

(b) *Toluene.*—Dried over anhyd.  $\text{Na}_2\text{SO}_4$ . To remove interferences, shake 500 mL toluene with 100 mL 1N  $\text{H}_2\text{SO}_4$ , distil, and dry with anhyd.  $\text{Na}_2\text{SO}_4$ . (Caution: See 51.011 and 51.039.)

(c) *Picric acid solns.*—(1) *Stock soln.*—Dissolve 2 g picric acid (Caution: See 51.029) in 100 mL  $\text{H}_2\text{O}$ -free toluene. (2) *Working soln.*—Dil. 1 mL stock soln to 100 mL with  $\text{H}_2\text{O}$ -free toluene.

(d) *Potassium carbonate soln.*—Dissolve 100 g  $\text{K}_2\text{CO}_3$  in 100 mL  $\text{H}_2\text{O}$ .

(e) *Formaldehyde.*—20%. Shake 1 L com. formalin (40%) with 100 g  $\text{MgCO}_3$  until nearly colorless and filter. Dil. 100 mL to 200 mL with  $\text{H}_2\text{O}$ . (Caution: See 51.058.)

(f) *Trimethylamine (TMA) std solns.*—(1) *Stock soln.*—Add 0.682 g  $(\text{CH}_3)_3\text{N} \cdot \text{HCl}$  to 1 mL  $\text{HCl}$  (1+3) and dil. to 100 mL with  $\text{H}_2\text{O}$ . Check basic N content of 5 mL aliquots by adding 6 mL 10%  $\text{NaOH}$  soln, distg into 10 mL 4% boric acid in micro-Kjeldahl distn app., 47.022, and titrg with 0.1N  $\text{H}_2\text{SO}_4$ , using indicator, 47.021(f). This soln is stable. (2) *Working soln.*—0.01 mg TMA-N/mL. Add 1 mL stock soln to 1 mL  $\text{HCl}$  (1+3) and dil. to 100 mL with  $\text{H}_2\text{O}$ .

#### 18.032

#### Preparation of Sample

Weigh 100 g minced or chopped, well mixed sample. Add 200 mL 7.5% trichloroacetic acid and blend. Centrf. blended soln at 2000–3000 rpm until supernate is practically clear.

#### 18.033

#### Determination

Pipet aliquot (preferably contg 0.01–0.03 mg TMA-N) into 20  $\times$  150 mm Pyrex g-s test tube and dil. to 4.0 mL with  $\text{H}_2\text{O}$ . For stds, use 1.0, 2.0, and 3.0 mL working std soln, dilg to 4.0 mL with  $\text{H}_2\text{O}$ ; for blank, use 4.0 mL  $\text{H}_2\text{O}$ . Add 1 mL  $\text{HCHO}$ , (e), 10 mL toluene from automatic pipet, and 3 mL  $\text{K}_2\text{CO}_3$  soln. Stopper tube and shake vigorously by hand ca 40 times. Pipet off 7–9 mL toluene layer into small test tube contg ca 0.1 g anhyd.  $\text{Na}_2\text{SO}_4$ . Avoid removing droplets of aq. layer. Stopper tube and shake well to dry toluene. Pipet 5 mL toluene layer into dry colorimeter tube. Add 5 mL picric acid soln and mix by swirling gently. Det.  $A$  at 410 nm against blank carried thru detn. Color is stable. If original aliquot contains  $>0.03$  mg TMA-N, dil. ext with trichloroacetic acid soln and repeat detn.

mg TMA-N/100 g sample (based on 1 mL aliquot)  
 $= (A/A') \times (\text{mg TMA-N/mL std soln}) \times \text{mL std soln used} \times 300$ .  
 Use  $A'$  of std nearest to  $A$  of sample for calcn.

#### Salt (Chlorine as Sodium Chloride)

#### Volumetric Method (17)—Official Final Action

#### 18.034

#### Reagents

(a) *Silver nitrate std soln.*—0.1N. Prep. as in 50.027 and stdze against 0.1N  $\text{NaCl}$  contg 5.844 g of pure dry  $\text{NaCl/L}$ .

(b) *Ammonium thiocyanate std soln.*—0.1N. Prep. as in 50.030(b) and stdze against 0.1N  $\text{AgNO}_3$ .

(c) *Ferric indicator.*—Satd soln of  $\text{FeNH}_4(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ .

#### 18.035

#### Determination

(a) *Shellfish meats.*—Weigh 10 g meats, liq., or mixed meats and liq., into 250 mL erlenmeyer or beaker.

(b) *Other fish products*.—Use suitable size sample, depending on NaCl content.

Add known vol. 0.1N AgNO<sub>3</sub> soln, more than enough to ppt all Cl as AgCl, and then add 20 mL HNO<sub>3</sub>. Boil gently on hot plate or sand bath until all solids except AgCl dissolve (usually 15 min). Cool, add 50 mL H<sub>2</sub>O and 5 mL indicator, and titr. with 0.1N NH<sub>4</sub>SCN soln until soln becomes permanent light brown. Subtract mL 0.1N NH<sub>4</sub>SCN used from mL 0.1N AgNO<sub>3</sub> added and calc. difference as NaCl. With 10 g sample each mL 0.1N AgNO<sub>3</sub> = 0.058% NaCl.

#### 18.036 Potentiometric Method—Official First Action

Prep. sample as in 18.012 and proceed as in 32.025–32.030.

#### 18.037 Indicating Strip Method—Procedure

See 24.011–24.014.

#### Sodium and Potassium (18)—Official Final Action

##### 18.038 Apparatus and Reagents

(a) *Glassware*.—Borosilicate glassware and intact Vycor, Pt, or Si crucible precleaned with dil. HNO<sub>3</sub> and rinsed in distd H<sub>2</sub>O immediately before use.

(b) *Distilled water*.—H<sub>2</sub>O, free from Na and K; either double-distd or deionized. Use for prep g stds and dilns.

(c) *Sodium std solns*.—(1) *Stock soln*.—1 mg Na/mL. Dry reagent grade NaCl 2 hr at 110°; cool in desiccator. Weigh 2.5421 g into 1 L vol. flask and dil. to vol. with H<sub>2</sub>O. (2) *Working solns for flame emission*.—0.01, 0.03, and 0.05 mg Na/mL. Pipet 1, 3, and 5 mL Na stock soln into sep. 100 mL vol. flasks; add 7 mL K stock soln and 2 mL HNO<sub>3</sub> to each flask; dil. to vol. with H<sub>2</sub>O. (3) *Working solns for flame absorption*.—0.00003, 0.0001, 0.0003, and 0.0005 mg Na/mL. Pipet 1 mL Na stock soln into 100 mL vol. flask and dil. to vol. with H<sub>2</sub>O. Pipet 0.3, 1.0, 3.0, and 5.0 mL dil'd stock soln into sep. 100 mL vol. flasks and dil. to vol. with H<sub>2</sub>O.

(d) *Potassium std solns*.—(1) *Stock soln*.—1 mg K/mL. Dry and cool reagent grade KCl as in (c). Weigh 1.9068 g into 1 L vol. flask and dil. to vol. with H<sub>2</sub>O. (2) *Working solns for flame emission*.—0.04, 0.07, and 0.10 mg K/mL. Pipet 4, 7, and 10 mL stock soln into sep. 100 mL vol. flasks; add 3 mL Na stock soln to each flask; dil. to vol. with H<sub>2</sub>O. (3) *Working solns for flame absorption*.—0.0001, 0.0005, 0.0007, and 0.0010 mg K/mL. Pipet 1 mL K stock soln into 100 mL vol. flask and dil. to vol. with H<sub>2</sub>O. Pipet 1, 5, 7, and 10 mL dil'd stock soln into sep. 100 mL vol. flasks and dil. to vol. with H<sub>2</sub>O.

##### 18.039

##### Wet Ashing

(Caution: See 51.011, 51.019, and 51.026.)

Prep. sample as in 18.012.

Weigh 1 g sample into 50 mL Pyrex beaker. Dry 2.5 hr at 110°, cool, and weigh if % solids is to be detd.

(a) *Samples with unknown or known high oil content*.—Add ca 10 mL pet ether, and warm on steam bath or low temp. hot plate until oil is extd. Decant and repeat until sample is defatted. Proceed as in (b).

(b) *Samples with low oil content*.—Add 5 mL HNO<sub>3</sub> (if total Cl content is desired, add enough 0.1N AgNO<sub>3</sub> to ppt chlorides (3.0 mL)) to each beaker. Digest on steam bath or low temp. hot plate until sample dissolves; evap. to dryness. Add 5 mL HNO<sub>3</sub> and take to dryness. Repeat. Add 2 mL HNO<sub>3</sub> and warm to dissolve. Proceed as in (c) or (d).

(c) *For flame emission*.—Transfer digest to 25 mL vol. flask with hot H<sub>2</sub>O, wash down sides of beaker 3 times with hot H<sub>2</sub>O,

and add washings to flask. Cool, and dil. to vol. with H<sub>2</sub>O. If particles are too finely dispersed to settle, centrf. aliquot at 2000 rpm.

(d) *For flame absorption*.—Transfer digest to 100 mL vol. flask and proceed as above. Dil. for direct readout as follows: Place 1 mL aliquot in 25 mL vol. flask and dil. to vol. with H<sub>2</sub>O for Na; place 2 mL aliquot in 10 mL vol. flask and dil. to vol. with H<sub>2</sub>O for K.

Prep. blank soln by dilg 2 mL HNO<sub>3</sub> to 100 mL with H<sub>2</sub>O.

##### 18.040

##### Dry Ashing

Prep. sample as in 18.012.

Weigh 4 g sample into crucible, and char on elec. hot plate or over low flame. Place in cold furnace and bring to 525°. Ash 2 hr to white ash. Cool, and weigh if total ash is desired.

Add 15 mL dil. HNO<sub>3</sub> (1+4) to crucible, breaking up ash with stirring rod if necessary. Filter thru acid-washed quant. paper into 100 mL vol. flask. Wash residue and paper 3 times with H<sub>2</sub>O. Dil. to vol. Proceed as in (a) or (b).

(a) *For flame emission*.—Read directly.

(b) *For flame absorption*.—Dil. for direct readout as follows: Place 1 mL aliquot in 100 mL vol. flask and dil. to vol. with H<sub>2</sub>O for Na; place 1 mL aliquot in 25 mL vol. flask and dil. to vol. with H<sub>2</sub>O for K.

Prep. blank soln by dilg 2 mL HNO<sub>3</sub> to 100 mL with H<sub>2</sub>O.

##### 18.041

##### Determination

(Caution: See 51.006 and 51.007.)

Follow manufacturer's directions for type of instrument available. Dil. samples if necessary to bring *T* readings within range of working stds. Read blank, stds, and samples at 589 nm for Na and 767 nm for K until results are reproducible; record % *T* or % absorption for each.

##### 18.042

##### Calculations

For flame emission photometers not equipped with direct readout:

$$\text{mg Na or K/100 g} = 100 \times F \times \left( \left[ \frac{(E_x + E_1)}{(E_2 - E_1)} \times (C_2 - C_1) \right] + C_1 \right) / \text{g sample},$$

where  $E_x$  = (% *T* of unknown) – (% *T* of blank);  $E_1$  = (% *T* of std of lower concn than sample) – (% *T* of blank);  $E_2$  = (% *T* of std of higher concn than sample) – (% *T* of blank);  $C_1$  = mg Na or K/mL in std of lower concn than sample;  $C_2$  = mg Na or K/mL in std of higher concn than sample;  $F$  = diln factor.

For flame absorption photometers: Convert % absorption to absorbance (*A*). Plot std curve of *A* against concn. Read unknown concns.

$$\text{mg Na or K/100 g} = (\text{Concn unknown} \times F \times 100) / \text{g sample}.$$

#### Crude Fat

#### By Acid Hydrolysis (19)—Official Final Action

##### 18.043

##### Preparation of Sample

Prep. sample according to type of pack as in 18.012 and keep ground material in sealed jar. If jar has been chilled, let sample come to room temp. and shake jar so that any sepd liq. is absorbed by fish. Open jar and stir contents with spatula, thoroly scraping sides and lid so as to incorporate any sepd liq. or fat.

**18.044****Determination**

Weigh 8 g well mixed sample into 50 mL beaker and add 2 mL HCl. Using stirring rod with extra large flat end, break up coagulated lumps until mixt. is homogeneous. Add addnl 6 mL HCl, mix, cover with watch glass, and heat on steam bath 90 min, stirring occasionally with rod. Cool soln and transfer to Mojonnier fat-extn flask. Rinse beaker and rod with 7 mL alcohol, add to extn flask, and mix. Rinse beaker and rod with 25 mL ether, added in 3 portions; add rinsings to extn flask, stopper with cork or stopper of synthetic rubber unaffected by usual fat solvs, and shake vigorously 1 min. Add 25 mL pet ether (bp <60°) to extn flask and repeat vigorous shaking. Centrf. Mojonnier flask 20 min at ca 600 rpm and proceed as in 14.019, beginning "Draw off as much as possible of ether-fat soln . . ."

Drying to const wt takes ca 40 min for fish. Long heating periods may increase wt of fat. If centrf. is not available, extn can generally be made by letting Mojonnier flask stand until upper liq. is practically clear, then swirling flask and again letting stand until clear. If troublesome emulsion forms, let stand, pour off as much of ether-fat soln as possible, add 1–2 mL alcohol to Mojonnier flask, swirl, and again let mixt. sep.

**Rapid Modified Babcock Method (20)—Official First Action**

(Applicable to raw, canned, and frozen fish)

**18.045****Determination**

(Caution: See 51.022, and 51.028(a) and (d).)

Weigh 9.0 g ground and mixed sample into Paley-type Babcock cheese bottle (Kimble Products No. 508, 20% size), stopper, and add ca 30 mL reagent prep'd by mixing equal vols HOAc and 70–72% HClO<sub>4</sub>. Place in H<sub>2</sub>O bath (2 L stainless steel beaker is satisfactory) maintained at 92±2°, swirling occasionally until no lumps remain (usually ca 20 min). Remove from bath, add reagent until fat is well up in calibrated neck of bottle, centrf. 2 min at ca 600 rpm, and read % fat with dividers, using bottom of top meniscus. If fat falls below calibration, add more reagent, centrf. 1 min, and read again.

With very fat fish, it may be necessary to use <9 g sample. In this case, correct reading by multiplying % fat by factor 9/g sample.

**18.046 In Fish Meal (21)—Official Final Action**

(Caution: See 51.009, 51.011, 51.039, and 51.046.)

Weigh 4–5 g sample to nearest 0.01 g into Alundum or paper extn thimble, cover with light layer of cotton, and ext with acetone in continuous extractor 16 hr. Distil off acetone until vol. in flask is 10–15 mL, transfer to 100 mL tared beaker, washing flask free of all oil with fresh acetone, and evap. with current of warm air. (Convenient method is to place flask on warm surface, e.g., over steam radiator, in front of small elec. fan.) When no H<sub>2</sub>O or acetone can be observed, place beaker in vac. oven at 80° and apply 610–640 mm (24–25"; 81.3–85.3 kPa) vac. 1 hr. Transfer to desiccator, cool, and weigh.

Transfer extd meal residue from thimble to 150 mL beaker. Remove any remaining solv. by heating on warm surface and then add 60 mL 4N HCl. Digest 1 hr at or near bp on hot plate, stirring occasionally with glass rod and adding H<sub>2</sub>O as needed to maintain vol. in beaker. (Complete removal of acetone is necessary before this digestion, otherwise vaporization of solv. will carry meal particles over side of vessel onto hot plate.) Filter thru 12.5 cm fluted paper. Wash residue on filter until acid-free, using Me red on portions of filtrate to follow progress of washing. Place filter and meal in 150 mL beaker and dry 1 hr in air oven at 80–90°. Transfer filter and contents to thimble and

ext 16 hr with acetone. Remove solv. and weigh ext as above. Sum of wts of exts = total fat.

**Semimicro Method (22)—Official Final Action****18.047****Apparatus**

**Extraction apparatus.**—See Fig. 18.01. (1) Reaction chamber (Corning Glass Works, No. 9820 tube (38 × 200 mm) sealed to 45/50 joint, No. 6560); (2) receiving chamber (45/50 joint, No. 6580); (3) No. 100–150 stainless steel screen. Add openings, Teflon stopcocks, and hooks as shown. Use Teflon ring to seal joint at screen. Opening in 1 lets atm. pressure be exerted on liq. surface when app. is inverted to filter sample. Flared opening in 2 is used to remove filtrate and to add solv. for second extn. Side outlet in 2 is used to apply rapid short gusts of vac. to remove max. amt solv. from samples or to aid in filtration.

**18.048****Extraction**

Close all stopcocks of extn app. Place Teflon-coated mag. stirring bar and ca 2–4 g accurately weighed sample, ground to pass No. 40 sieve, in reaction chamber. Add 30 mL CHCl<sub>3</sub>, 20 mL MeOH, and 7 mL H<sub>2</sub>O. Attach receiving chamber with screen inserted, using springs or rubber bands. Fasten app. on stirring plate with std clamp and stir mag. 15 min. Remove app. and invert. Open stopcock of reaction chamber (now on top) to equalize air pressure.

Place opening of receiving chamber (now on bottom) in 100 mL graduate contg 10 mL H<sub>2</sub>O, and open top stopcock. Close bottom stopcock. With top stopcock open, briefly apply vac. from aspirator to remove solvs more thoroly, and drain solv. into graduate. Invert app. to original position. Add 10 mL CHCl<sub>3</sub> thru top stopcock. Invert app. and drain solv. into same 100 mL graduate. Invert app. to original position and close bottom stopcock. Slowly add 40 mL CHCl<sub>3</sub> thru top stopcock so that sides of app. will be rinsed clean.

Close top stopcock, place app. on stirrer, and ext 2 min. Repeat rinsing of app. as above, beginning "Remove app. and invert." except use 2 rinses of 10 mL CHCl<sub>3</sub>. Collect extn solv. and rinses in same graduate.

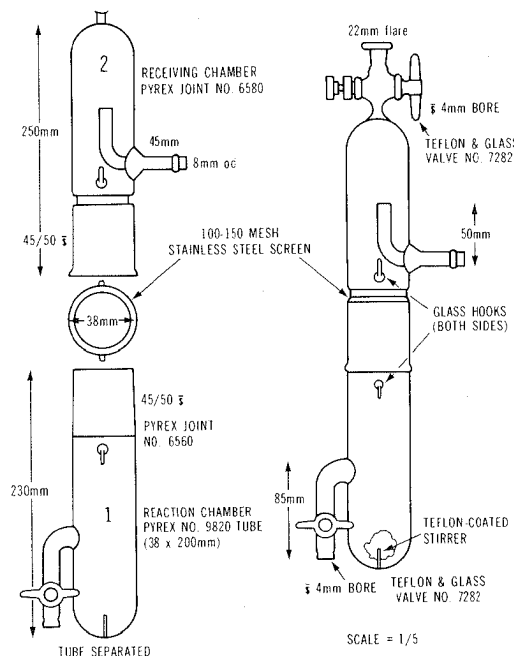

FIG. 18.01—Extraction apparatus

## 18.049

## Determination

Let filtrate stand overnight to clarify; then record vol.  $\text{CHCl}_3$  layer. Remove most of MeOH layer by suction. Mix contents of graduate well; remove remaining MeOH layer and small amt  $\text{CHCl}_3$  layer by suction. Pipet 25–50 mL  $\text{CHCl}_3$  layer into 50 mL tared beaker, and dry under N in  $50^\circ \text{H}_2\text{O}$  bath. Place dried sample in vac. desiccator over  $\text{P}_2\text{O}_5$  or silica gel  $\geq 90$  min before weighing.

$$\text{Wt lipid in sample} = (W \times V)/V'$$

where  $W$  = wt lipid in aliquot taken,  $V$  = vol.  $\text{CHCl}_3$  layer, and  $V'$  = vol.  $\text{CHCl}_3$  aliquot taken.

## Volatile Fatty Acids

## Column Chromatographic Method (23)—Official Final Action

## 18.050

## Apparatus

(a) *Steam distillation assembly*.—Fig. 18:02. Assembly consists of boiler flask (3 L) giving steam at const rate so as to produce const rate of distn, distn flask, condenser, and 200 mL vol. flasks as receivers. Std distn flask with side arm (ca 9 mm od) attached near center of neck, and with steam inlet tube (ca 10 mm od), is satisfactory. Heating coil of steam generator is made by winding 1.5 m (5') 28 gage Chromel wire (or equiv.) around hollow pipe ca 6 mm (0.25") diam. and heating red hot to detemper wire. Leads into boiler flask are brass, Cu, or other nonferrous metal ca  $3/32$ " (2 mm) diam. Insulate and shield elec. leads and contacts to avoid possible shorting and elec. shocks.

Any similar distn assembly may be used if it is of capacity to handle vols specified in method and gives  $57 \pm 2\%$  recovery of acetic acid on distn.

(b) *Chromatographic tube*.—Approx.  $15 \times 250$  mm.

(c) *Source of air pressure or compressed N gas equipped with pressure regulator*.—If such source is not available, following system serves purpose: Fit 1 L side arm flask with 2-hole rubber stopper. Pass glass manometer tube 70 cm long thru

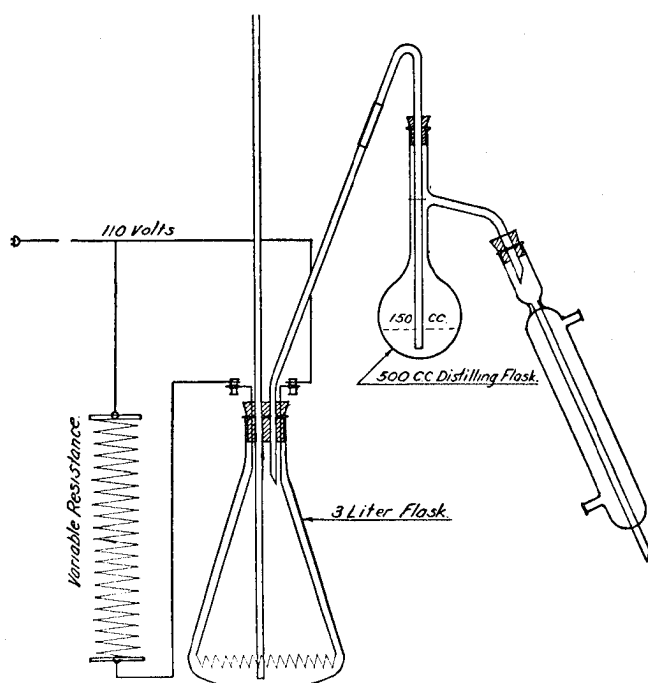

FIG. 18:02—Steam distillation assembly

one hole in stopper so that it reaches bottom of flask, and thru other hole pass glass tube ca 8 cm long, whose upper end is connected to top of chromatgc tube by rubber tubing. Connect rubber hand-aspirator bulb to side arm of flask. Fill flask with Hg to depth of 1.5 cm. (Ht of Hg column in manometer tube indicates pressure in system; 25 cm is equiv. to ca 5 lb.) To maintain reservoir pressure when chromatgc tube is disconnected, fit stopcock into line leading from flask to chromatgc tube; and to prevent valve in hand aspirator from leaking, insert second stopcock between side arm and bulb.

(d) *Rubber bulb*.—5 mL. (Type used on dropping bottles.)

(e) *Microfunnel*.—Buchner-type, 2 mL capacity with coarse fritted disk; Corning No. 36060.

## 18.051

## Reagents

(a) *Butanol in chloroform*.—1%. Remove alcohol from USP  $\text{CHCl}_3$  by washing 3 times with  $\frac{1}{2}$  vol.  $\text{H}_2\text{O}$ . Add 10 mL  $n$ -BuOH to 1 L washed  $\text{CHCl}_3$  in separator, shake vigorously, add 25 mL  $\text{H}_2\text{O}$ , and shake again. Let stand until lower layer clears, and drain. Discard upper aq. layer. Store in contact with granular anhyd.  $\text{Na}_2\text{SO}_4$ .

(b) *Butanol in chloroform*.—10%. To 900 mL USP  $\text{CHCl}_3$  (not previously washed) in separator add 100 mL  $n$ -BuOH, shake vigorously, add 25 mL  $\text{H}_2\text{O}$ , and shake again. Let  $\text{CHCl}_3$  stand until clear, and drain. Discard aq. layer. Store in contact with granular anhyd.  $\text{Na}_2\text{SO}_4$ .

(c) *Alphamine Red R indicator*.—Dissolve 50 mg mono- $\text{NH}_4$  salt 3-(4-anilino-1-naphthylazo)-2,7-naphthalene disulfonic acid (Eastman Kodak Co. No. 6410) in 25 mL  $\text{H}_2\text{O}$ . (Red soln produced by 1 drop indicator in 20 mL  $\text{H}_2\text{O}$  must be changed to violet by 1 drop 0.01N HCl.) Prep. fresh weekly.

(d) *Cresol red indicator*.—Dissolve 50 mL  $o$ -cresolsulfonphthalein in 20 mL alcohol, add 1.3 mL 0.1N NaOH, and dil. to 50 mL with  $\text{H}_2\text{O}$ . Use 2 drops for each 25 mL aq. soln.

(e) *Barium hydroxide std soln*.—0.01N. (Store in polyethylene or paraffin-lined bottle and protect from  $\text{CO}_2$  of atm. with soda-lime or Ascarite; dispense from 10 mL buret.) (0.01N NaOH may be used instead of  $\text{Ba}(\text{OH})_2$  except in titrn of Soln B, 18.054. NaOH soln must be used in titrn of Soln A, 18.054, since Na salts are required for chromatgy.)

(f) *Sodium acetate-sodium chloride soln*.—Dissolve 12 g NaCl and 25 g  $\text{NaOAc} \cdot 3\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 500 mL.

(g) *Silicic acid*.—Reagent grade "100-mesh" powder, suitable for chromatgy (Mallinckrodt Chemical Works No. 2847, or equiv.).

## 18.052

## Standardization of Distillation Apparatus

Place app., 18.050(a), in laboratory so that it is free from drafts and sudden changes in temp. Make mark on boiler flask at 1.5 L level, fill to this mark with  $\text{H}_2\text{O}$ , heat to boiling, and boil several min before starting distn. Transfer 150 mL  $\text{H}_2\text{O}$  to distn flask, add 1 drop  $\text{H}_2\text{SO}_4$  (1+1), connect condenser, insert steam inlet tube into distn flask, and bring contents of flask to incipient boiling with burner. Connect steam inlet tube with steam supply from boiler and steam distil. Regulate rate of evolution of steam and ht of small flame of burner under distn flask so that vol. of liq. in distn flask is kept const at 150 mL and distillate collects at 200 mL/hr. (Period of collection may vary 5 min for 200 mL distillate. Keep vol. in distn flask at  $150 \pm 10$  mL. Stop boiling, if necessary, to permit test of constancy of 150 mL vol. by momentarily interrupting steam supply. Few trials will show conditions necessary to maintain const vol. in distn flask and const rate of distn.) Det. blank on 2 successive 200 mL portions of distillate by titrg with 0.01N alkali (phthln) in  $\text{CO}_2$ -free atm.

Transfer 50 mL ca 0.1N HOAc (concn must be accurately

known) to distn flask; add 1 drop  $\text{H}_2\text{SO}_4$  (1+1) (avoid contact with neck of flask) and 100 mL  $\text{H}_2\text{O}$ . Collect 200 mL distillate and titr. with 0.1N alkali. Correct for titrn blanks and compute % acid distd. Distn technic and app. are satisfactory when recovery is  $57 \pm 2\%$ . App. so adjusted gives recoveries ( $\pm 2\%$ ) of formic, propionic, and butyric acids of 40.5, 81, and 92%, resp. (JAOAC 21, 684, 688(1938)), on 200 mL distillate.

**18.053****Preparation of Solution**

Weigh 50 g comminuted material, **18.012**, into tared 500 mL wide-mouth erlenmeyer, add ca 150 mL  $\text{H}_2\text{O}$ , stopper flask, and shake vigorously ca 1 min to effect thoro suspension of material. Add 25 mL 1N  $\text{H}_2\text{SO}_4$ , mix, ppt proteins with 20% *phosphotungstic acid soln* (40 mL is usually enough), make to 300 g with  $\text{H}_2\text{O}$ , shake vigorously ca 1 min, and filter thru 24 cm rapid folded paper.

**18.054****Distillation and Computation of Volatile Acid Number**

Pipet 150 mL prepd soln into distn flask of app. and make acid to Congo red paper with  $\text{H}_2\text{SO}_4$  (1+1). Steam distil as in **18.052**. Collect 200 mL distillate, titr. with 0.01N NaOH to phthln end point, and designate as A. Collect second 200 mL portion distillate, titr. with 0.01N  $\text{Ba}(\text{OH})_2$  soln to phthln end point, and designate as B. To calc. volatile acid number, multiply titrn obtained on distillate A, corrected for blank, by 4.

**18.055****Determination of Formic Acid (24)**

(Caution: See **51.079**.)

Add 2 drops satd  $\text{Ba}(\text{OH})_2$  soln to distillate B, **18.054**, and evap. to dryness on steam bath. Add ca 5 mL  $\text{H}_2\text{O}$  to residue and 1 mL more of 1N HCl than necessary to liberate volatile acids. Filter thru small paper into 125 mL erlenmeyer with  $\text{F}$  joint, and wash paper with  $\text{H}_2\text{O}$  in such manner that total filtrate equals 30–40 mL. Add 10 mL NaOAc-NaCl soln and 10 mL 5%  $\text{HgCl}_2$  soln. Connect flask with  $\text{F}$  air condenser and place on steam bath 2.5 hr.

With suction thru glass siphon attached to funnel by rubber stopper, transfer ppt of  $\text{Hg}_2\text{Cl}_2$  to previously weighed microfunnel, **18.050(e)**, provided with mat of asbestos ca 2 mm thick. Rinse flask with  $\text{H}_2\text{O}$  followed by alcohol. Dry 30 min at  $100^\circ$ , cool, and weigh. Weigh funnel with another funnel, prepd with asbestos and treated similarly to one contg ppt, as counterpoise.

$\text{Wt } \text{Hg}_2\text{Cl}_2 \text{ (mg)} \times 0.0975 = \text{mg formic acid in distillate}$ . To calc. total formic acid originally present in aliquot of sample in distn flask before distn, divide mg formic acid found by 0.24 (fraction formic acid distd in second 200 mL distillate) and multiply by 4 to obtain formic acid in 100 g sample being analyzed. (Note: Factor 4 applies only to products prepd as in **18.053**. If other sample wts and aliquots are used as for eggs, **17.041**, appropriate factor must be used.)

**Chromatographic Separation of  $\text{C}_2$  to  $\text{C}_4$   
Saturated Fatty Acids (25)**

**18.056****Preparation of Partition Column**

To 5 g silicic acid in glazed porcelain evapg dish add 1 mL Alphamine Red R indicator soln and just enough 1N  $\text{NH}_4\text{OH}$  to give alk. color of the indicator (1 drop is usually enough). Add max. amt of  $\text{H}_2\text{O}$  that the silicic acid will hold without becoming sticky or agglomerating in the  $\text{BuOH-CHCl}_3$  soln. (This amt must be detd for each batch of silicic acid and usually varies from 50 to 75% of wt of silicic acid.) Mix thoroly with pestle until homogeneous. Add ca 25 mL 1%  $\text{BuOH}$  in  $\text{CHCl}_3$ , and mix to

form slurry that pours readily. Pour this slurry into chromatg tube contg small cotton plug in neck of constricted end. To avoid air pockets, tilt tube slightly while pouring. If air bubbles form while pouring, eliminate by stirring suspension in tube with long glass rod.

Clamp tube vertically in ring stand. In top insert 1-hole rubber stopper fitted with glass tube bent to  $90^\circ$  angle and held in place by Bunsen clamp against pressure to be exerted. Connect bent glass tube to pressure source, **18.050(c)**. Adjust pressure to 5–10 psi (34.5–68.9 kPa) so that excess solv. is forced thru column dropwise.

During removal of excess solv., gel packs down. As column packs down, particles of gel adhere to wall of tube, but eventually gel leaves wall of tube relatively clean. This is point of optimum density of column, and column is ready for use. Apply pressure until solv. reaches surface of column. If solv. passes below surface, causing drying or "cracking" of column, or if air pockets are present, extrude packing from tube, reslurry with solv., and repack column.

**18.057****Test of Silicic Acid for Suitability and Standardization of Column**

(a) *Preparation of std acid solns.*—Pipet 1 mL of each of following acids into sep. 1 L vol. flasks: Acetic, propionic, butyric, and valeric. Dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Pipet 10 mL of each soln into sep. 125 mL erlenmeyers and titr. with 0.01N NaOH, using cresol red indicator, to pink persisting ca 45 sec.

$$\text{mL } 0.01N \text{ NaOH} \times \text{normality} \times F = \text{mg acid/mL std acid soln,}$$

where  $F = 6.01$  for HOAc; 7.41, propionic; 8.81, butyric; and 10.2, valeric acid.

(b) *Preparation of std acid mixture.*—Pipet 50 mL of each std acid soln into same 250 mL vol. flask and dil. to vol. with  $\text{H}_2\text{O}$ . Conc'n of each acid in std acid mixt. =  $1/5$  conc'n in std acid soln.

(c) *Preparation of known samples.*—Pipet 5 and 25 mL aliquots of std acid mixt. into sep. 50 mL beakers. Just neutze with 0.1N NaOH, using phthln, and add 10 drops excess. Evap. to dryness on steam bath. If desired, chromatograph acids individually by using 5 mL aliquots of each std soln and 5 mL aliquots of 5-fold dilns of each std acid soln. Combinations approximating compositions in samples may also be prepd.

(d) *Column separation.*—(Good sepn and yields depend upon transfer of sample to column with amt of solv. specified.) To dry residue of Na salts add 2 mL 1%  $\text{BuOH}$  in  $\text{CHCl}_3$  soln and while stirring with glass rod add  $\text{H}_2\text{SO}_4$  (1+1) dropwise until all Na salts are converted to free acids (acid to Congo red paper). Add 1 g anhyd.  $\text{Na}_2\text{SO}_4$ .

Acids elute in following order: valeric, butyric, propionic, and acetic. Place 50 mL graduate under column as receiver. Decant supernate onto column, pouring it slowly down side of tube without disturbing level surface of column. Apply pressure until solv. reaches surface of gel. Wash beaker with 1 mL solv., pour onto column, and with stirring rod transfer residue in beaker to column. Apply pressure until solv. just disappears into  $\text{Na}_2\text{SO}_4$  layer. Wash beaker with another 1 mL solv., transfer to column, wash inside of tube with 1 mL solv., and apply pressure until solv. just disappears into  $\text{Na}_2\text{SO}_4$  layer. Fill tube with solv. and apply pressure. Each time front (lower edge) of a band reaches point 2–5 mm above narrowest portion of constriction of tube, record vol. collected and change receiver. For each acid, total cumulative vol. is threshold vol. used for identifying bands in succeeding runs. After propionic acid (third band) has been eluted, fill tube with 10%  $\text{BuOH}$  in  $\text{CHCl}_3$  and use this solv. to elute HOAc. (Propionic acid is eluted after ca 50 mL 1%  $\text{BuOH}$  in  $\text{CHCl}_3$  has passed thru column. Observe vol. actually used. In

succeeding runs, change to 10% BuOH in  $\text{CHCl}_3$  at that vol. whether or not propionic acid is present.)

Transfer eluates to sep. 125 mL erlenmeyers, rinsing each graduate with three 5 mL portions  $\text{H}_2\text{O}$ . Add 1 drop cresol red indicator soln and titr. with 0.01N alkali. As end point approaches, stopper flask and shake vigorously to completely extract acids from solv. phase. Correct titrn of each eluted band for blank as follows: Collect 25 mL BuOH- $\text{CHCl}_3$  mixt. from column before any acids are transferred, add 15 mL boiled and cooled  $\text{H}_2\text{O}$ , and titr. as above with 0.01N alkali.

If bands are not clearly differentiated or recoveries are <90%, reject the silicic acid. (Addnl stdzn with respect to threshold vol. may be desirable for identification in some instances, 18.058.)

#### 18.058

#### Identification and Determination

Add 1 drop 1N NaOH to neutzd distillate A obtained in 18.054 and evap. to small vol. Transfer to 50 mL beaker, evap. to dryness on steam bath, and proceed exactly as in 18.057(d).

Identify acids by comparing their threshold vols with those for approx. same amts and ratios of known acids found in stdzn operation. Threshold vol. of given amt of each fatty acid is characteristic and reproducible under similar conditions. However, if conditions change, such as use of different batch of silicic acid or different amt of same batch, or different amt of  $\text{H}_2\text{O}$ , threshold vol. for each acid must be redetd. (If present, isobutyric acid is measured as *n*-butyric acid.) For further identification as characteristic salts, see JAOAC 28, 644(1945). Acids may also be identified by paper chromatog, 14.101.

mg Acid/100 g sample

$$= \text{mL } 0.01N \text{ NaOH (corrected for blank)} \times \text{normality} \times F,$$

where *F* includes equiv. wts of acids, corrected for distn recoveries, and dilns. *F* = 421 for HOAc; 366, propionic; and 383, butyric acid.

(Note: Factors given apply only to products prepd as in 18.053. If other sample wts and aliquots are used as for eggs, 17.041, appropriate factors must be used.)

#### 18.059 Gas Chromatographic Method (26) Official Final Action

Proceed as in 17.043–17.047, except substitute 18.053 for 17.046. To calc. volatile acid no., multiply mL 0.01N NaOH required to neutze 200 mL distillate, corrected for blank, by 4.

#### Histamine

#### Biological Method (27)—Official Final Action

#### 18.060

#### Apparatus

(a) *Kymograph*.—With horizontal muscle lever arm having friction or gravity writing point.

(b) *Muscle bath*.—At least 50 mL capacity, in 37° const temp. bath. See Fig. 18.03. May be conveniently filled and emptied thru 3-way stopcock; 1 tube connected to reservoir of Ringer-Locke soln thru bulb or coil immersed in bath; other tube connected to vac. thru suction flask as waste receiver. Bubble air, filtered thru cotton, slowly and continuously around intestine from fine capillary tube.

#### 18.061

#### Reagents

- Sodium chloride stock soln.—180 g/L.
- Potassium chloride stock soln.—42 g/500 mL.
- Sodium bicarbonate stock soln.—15 g/500 mL.
- Atropine sulfate stock soln.—1.0 g/500 mL.
- Calcium chloride stock soln.—24 g anhyd. salt/500 mL.

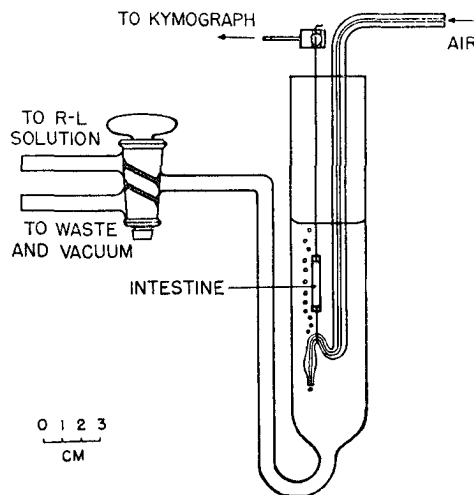

FIG. 18.03—Muscle bath

(f) *Ringer-Locke soln.*—NaCl, 0.9%; KCl, 0.042%;  $\text{CaCl}_2$ , 0.024%;  $\text{NaHCO}_3$ , 0.015%; glucose, 0.1%; and atropine sulfate, 0.001%. Add 100 mL (a) and 10 mL (b), (c), and (d) to 2 L vol. flask. Add  $\text{H}_2\text{O}$  to vol. of ca 1800 mL and then 10 mL (e) while swirling. Add 2 g anhyd. glucose before use. Dil. to vol. with  $\text{H}_2\text{O}$ . Keep soln contg glucose in refrigerator when not in use, discarding when it becomes moldy.

(g) *Histamine diphosphate std solns.*—0.1 mg histamine diphosphate/mL boiled  $\text{H}_2\text{O}$ . If stored in refrigerator when not in use, it will keep  $\geq 3$  months. Prep. dild stds of 0.01 mg/mL and 0.005 mg/mL as required. If bath <50 mL is used, prep. dilns of (g) with (f) to avoid diln of bath when stds are added.

(h) *Guinea pig intestine*.—Use guinea pigs weighing 300–400 g. Starve pig 24 hr, kill by blow on head, and remove intestine, severing at point proximal to ileocecal junction, retaining ca 12 cm of terminal ileum. Wash this section with soln (f) and use ca first 2 cm for first series of assays. Place remainder of intestine on cotton in petri dish, just covering with soln (f). Prop lid to admit air and store in refrigerator at ca 4–7° (40–45°F). (Below 4° intestine loses its activity.) Use addnl portions of intestine as required as long as material shows enough response to histamine stimulus (usually 8 days). These addnl portions of intestine are not as sensitive as ileum but give uniform response with barely noticeable pendulum movements after storage.

#### 18.062

#### Preparation of Sample

See 18.012. Freeze ground sample for storage, if desired.

#### 18.063

#### Assay

Weigh 10 g prepd sample into small mortar. Add enough  $\text{H}_2\text{O}$  to make smooth paste while grinding with pestle. Transfer paste with little addnl  $\text{H}_2\text{O}$  to 100 mL Kohlrausch flask and add 1 mL HCl (1+1). Add  $\text{H}_2\text{O}$  to total vol. of ca 70 mL, mix well, and heat flask ca 20 min in boiling  $\text{H}_2\text{O}$  bath. Remove from bath, cool, dil. to vol. with  $\text{H}_2\text{O}$ , mix, and filter on Whatman No. 12 folded paper (or equiv.). (Ext filters slowly but only ca 5 mL need be collected for analysis.) Filtrate may be stored in refrigerator 10 days without diminished activity. Neutze 1 mL filtrate with 2 mL 1%  $\text{NaHCO}_3$  soln. Dil. to 10 mL with Ringer-Locke soln (without glucose).

Attach intestine to muscle lever and let stand at least 0.5 hr in 50 mL Ringer-Locke soln, (f), in const temp. bath at 37°. With fresh ileum, contractions and relaxations may be non-rhythmic for ca 2–3 hr with extreme and not always uniform

responses to histamine stimuli. Detns may be performed during this period, but it is necessary to add small and increasing amts of dild stds to stabilize intestine response, and to check responses several times until readings are reproducible.

Add known amt of dil. std soln, (g), to bath, record response, and remove writing lever from contact with drum. Drain inner bath, add fresh 37° soln (f) to wash chamber and intestine, remove, and refill with fresh soln. Let intestine rest 3 min. Est. amt and diln of neutzd fish ext that will give approx. equal response, and add to bath. Repeat recording of response, washing muscle chamber, and resting 3 min. During this interval, measure step hts with mm scale and calc. amt std necessary to match assay step ht. Alternately add ext and std as above until exact match is obtained.

#### Chemical Method (28)—Official Final Action

(Use H<sub>2</sub>O redistd from glass for prepn of reagents and for detns. Do not clean glassware with soap; use fresh chromic acid cleaning soln, rinsing well with tap H<sub>2</sub>O, then 3 times with distd H<sub>2</sub>O, and 3 times with redistd H<sub>2</sub>O. Alcohol may be used to soak or rinse glassware.)

#### 18.064

#### Reagents

(a) *Benzene-*n*-butanol mixture*.—(3+2) v/v.

(b) *Cotton acid succinate*.—Dissolve 5 g anhyd. NaOAc, fused just before use, and 40 g succinic anhydride in 300 mL HOAc in 500 mL erlenmeyer. Immerse 10 g absorbent cotton, cut into strips, in soln; attach drying tube contg drying agent, and heat 48 hr at 100°. (Flask may be immersed to neck in active steam bath.) Filter; wash well with H<sub>2</sub>O, HCl (1+9), H<sub>2</sub>O, and finally with alcohol. Dry in vac. oven at 100°.

(c) *Diazonium reagent*.—Dissolve 0.1 g *p*-nitroaniline, recrystd from hot H<sub>2</sub>O, and dil. to 100 mL with 0.1*N* HCl. Store in refrigerator. Dissolve 4 g NaNO<sub>2</sub> in H<sub>2</sub>O and dil. to 100 mL. Store in refrigerator. Just before use, place 10 mL *p*-nitroaniline soln in ice bath 5 min, add 1 mL NaNO<sub>2</sub> soln, mix, and let stand in bath ≥5 min before use.

(d) *Coupling buffer*.—Dissolve 7.15 g Na metaborate (NaBO<sub>2</sub>) and 5.7 g Na<sub>2</sub>CO<sub>3</sub> in H<sub>2</sub>O, and dil. to 100 mL. Store in polyethylene bottle.

(e) *Barbital buffer*.—Dissolve 10 g Na barbital in 1 L H<sub>2</sub>O and adjust to pH 7.7 with HOAc (1+15) (ca 25–30 mL), using pH meter. Store in refrigerator to prevent mold growth. Dissolve any ppt by warming before use. (50–250 mL bottle of the buffer may be kept at room temp. and replenished from main supply when mold growth is apparent.)

(f) *Histamine std solns*.—Dry histamine.2HCl (USP Ref. Std or material checked against Std as in 18.066) 2 hr over H<sub>2</sub>SO<sub>4</sub>. Dissolve 0.1656 g dried histamine.2HCl in H<sub>2</sub>O and dil. to 100 mL (1 mL = 1 mg histamine). Dil. 10 mL of this stock soln to 100 mL with H<sub>2</sub>O (1 mL = 100 μg histamine). Dil. 5 mL of this dil. std soln and 5 mL MeOH to 100 mL with H<sub>2</sub>O (1 mL = 5 μg histamine). Store in cold. Prep. fresh stds weekly.

(g) *4-Methyl-2-pentanone (methyl isobutyl ketone)*.—Com. purified grade (Eastman Kodak Co. No. 416 has been found satisfactory). To recover used ketone, wash once with satd NaHCO<sub>3</sub> soln and 3 times with H<sub>2</sub>O, distil, retaining fraction boiling at 115–118°, and check *A* at 475 nm.

(h) *Benzaldehyde*.—Cl-free.

(i) *Dilute sulfuric acid*.—0.40±0.02*N*, accurately stdzd.

#### 18.065

#### Preparation of CAS Column

Prep. column by firmly placing small plug of cotton acid succinate (CAS) (ca 50 mg) in column prepd by cutting off or blowing out bottom of 15 mL centr. tube. Wash plug with three

15 mL portions H<sub>2</sub>O and two 3 mL portions alcohol. Let solvs drip thru CAS, syringing out column by blowing out last portion of each solv., using 10 mL syringe with needle inserted thru rubber stopper. CAS plugs may be reused for months by washing shortly after use with H<sub>2</sub>O and alcohol as above, and protecting from dust with inverted beaker.

#### 18.066

#### Determination

Transfer 10 g prepd sample, 18.062, to semimicro container of high-speed blender, add ca 50 mL MeOH, and blend ca 2 min. Transfer to 100 mL g-s vol. flask, rinsing lid and blender jar with MeOH and adding rinsings to flask. Heat in H<sub>2</sub>O bath to 60° and let stand 15 min at this temp. Cool to 25°, dil. to vol. with MeOH, and filter thru folded paper. Alcohol filtrate may be stored in refrigerator several weeks. (Light powdery ppt sepg on storage may be ignored.)

Dil. 5 mL filtrate to 100 mL with H<sub>2</sub>O (disregard turbidity). Pipet 5 mL aliquot into 16 × 150 mm g-s test tube, and add 1 drop benzaldehyde (Cl-free) and 0.2 mL 20% NaOH. (pH after adding alkali should be ca 12.4–12.5.) Shake vigorously ca 25 times. Let stand 2 min and add 5 mL benzene-BuOH mixt. Shake vigorously ca 25 times and let stand 5 min to sep. If emulsion forms, centr.

Transfer upper layer with fine-tip tube equipped with rubber bulb to previously prepd CAS column, avoiding transfer of any aq. phase. Re-ext aq. soln with 5 mL benzene-BuOH mixt. as before, shaking, letting stand 5 min, and transferring upper layer to column. Rinse lip and sides of column with fine stream of alcohol from wash bottle, syringing out CAS. Wash column with 3 mL alcohol; syringe out; wash with two 3 mL portions H<sub>2</sub>O, and syringe out. Discard solvs and washings.

Elute histamine from CAS into 25 mL g-s erlenmeyer by washing down sides of tube with 2.0 mL 0.40±0.02*N* H<sub>2</sub>SO<sub>4</sub> (vol. and concn of acid are critical) followed by 3 mL H<sub>2</sub>O. Syringe out after dripping ceases.

Cool eluate in ice bath, weighting flask with lead ring or clamp to prevent tipping, and let stand 5–10 min. Add 0.5 mL cooled diazonium reagent and let stand 5 min in ice bath. Add 0.50 mL coupling buffer (vol. is critical; Ostwald pipet is convenient) with continuous shaking or swirling to avoid localized alkyl (pH after addn of coupling buffer, 5–6). Let stand 5 min in ice bath. Sat. soln with ca 0.25 g powd Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O added in one portion. Shake soln immediately and continuously ca 30 sec to ensure rapid and complete satn (final pH ca 8.6). Let stand 15 min in ice bath.

Pipet in 5.0 mL methyl isobutyl ketone and shake vigorously 25 times. Immediately transfer both layers to 16 × 150 mm test tube (do not rinse) and let stand 10 min at room temp. to sep. and to warm up. Transfer upper layer with fine-tip dropper to second 16 × 150 mm g-s test tube contg 5.0 mL barbital buffer. Avoid transferring aq. and solid phases (if present) (transfer need not be quant.). Shake vigorously ca 25 times (pH of barbital buffer after washing, ca 8.3–8.4). Let stand 10 min to sep.

Transfer upper layer with fine-tip dropper to 1 cm cell and det. *A* at 475 nm against methyl isobutyl ketone. Repeat detn on samples yielding *A* values >25 μg std by dilg 1 mL MeOH filtrate to 100 mL with H<sub>2</sub>O. Alternatively, aq. diln may be dild 1+4 (or more) with H<sub>2</sub>O.

Conduct std and blank thru detn as follows: Pipet 5 mL 5 μg/mL histamine std soln into 16 × 150 mm g-s test tube and pipet 5 mL 5% MeOH into similar tube for blank. Proceed as in detn, beginning, par. 2, line 2, "... add 1 drop benzaldehyde

Subtract blank *A* from *A* of std (*A'*) and of sample (*A*) and calc. histamine in sample aliquot:

$$\mu\text{g Histamine} = \Delta A \times 25/\Delta A'$$

**Fluorometric Method (29)—Official Final Action**

(Rinse all plastic and glass containers with HCl (1+3) and H<sub>2</sub>O before use.)

**18.067****Apparatus**

(a) *Chromatographic tube*.—200 × 7 (id) mm polypropylene tube. (Chromaflex, Kontes Glass Co. No. K-420160, or equiv.) fitted with Kontes No. K-422372 Kel-F Hubs and ca 45 cm Teflon tubing. Control flow rate at >3 mL/min by adjusting ht of column relative to tubing outlet.

(b) *Photofluorometer*.—Perkin-Elmer Model 203 or 204 with medium pressure Hg lamp, American Instrument Co. No. 4-7125 with GEF4T4/BL lamp, or equiv. instrument with excitation at 350 nm and measuring emission at 444 nm.

(c) *Repipets*.—1 and 5 mL (Labindustries, 620 Hearst Ave, Berkeley, CA 94710, or equiv.).

**18.068****Reagents**

(a) *Ion exchange resin*.—Bio-Rad AG 1-X8, 50–100 mesh (Bio-Rad Laboratories, 32nd & Griffin Ave, Richmond, CA 94804) or Dowex 1-X8, 50–100 mesh. Convert to -OH form by adding ca 15 mL 2*N* NaOH/g resin to beaker. Swirl mixt. and let stand <30 min. Decant liq. and repeat with addnl base. Thoroughly wash resin with H<sub>2</sub>O, slurry into fluted paper (S&S No. 588, or equiv.), and wash again with H<sub>2</sub>O. Prep. resin fresh weekly and store under H<sub>2</sub>O.

Place glass wool plug in base of tube, (a), and slurry in enough resin to form 8 cm bed. Maintain H<sub>2</sub>O level above top of resin bed at all times. Do not regenerate resin in packed column; rather, use batch regeneration in beaker when necessary. Wash column with ca 10 mL H<sub>2</sub>O before applying each ext.

(b) *Phosphoric acid*.—3.57*N*. Dil. 121.8 mL 85% H<sub>3</sub>PO<sub>4</sub> to 1 L. For other concn H<sub>3</sub>PO<sub>4</sub>, vol. required for 1 L 3.57*N* acid = 17493/(density H<sub>3</sub>PO<sub>4</sub> × % H<sub>3</sub>PO<sub>4</sub>). Stdze 5.00 mL by titrn with 1.00*N* NaOH to phthln end point, and adjust concn if necessary.

(c) *o-Phthalicdicarboxaldehyde (OPT) soln*.—0.1%. Dissolve 100 mg OPT (Aldrich Chemical Co., Inc., No. P3,940-0, or equiv.) in 100 mL distd-in-glass MeOH (Burdick & Jackson Laboratories, Inc., or equiv.). Store in amber bottle in refrigerator. Prep. fresh weekly.

(d) *Histamine std solns*.—Store in refrigerator. (1) *Stock soln*.—1 mg/mL as free base. Accurately weigh ca 169.1 mg histamine.2HCl (98%, Aldrich Chemical Co., Inc., No. 11,260-7, or equiv.) into 100 mL vol. flask, and dissolve and dil. to vol. with 0.1*N* HCl. Prep. fresh weekly. (2) *Intermediate soln*.—10 µg/mL. Pipet 1 mL stock soln into 100 mL vol. flask, and dil. to vol. with 0.1*N* HCl. Prep. fresh weekly. (3) *Working solns*.—0.5, 1.0, and 1.5 µg/5 mL. Pipet 1, 2, and 3 mL intermediate soln into sep. 100 mL vol. flasks, and dil. each to vol. with 0.1*N* HCl. Prep. fresh daily.

**18.069****Preparation of Standard Curve**

Pipet duplicate 5 mL aliquots of each working std soln into sep. 50 mL glass or polypropylene erlenmeyers. Pipet in 10 mL 0.1*N* HCl to each flask and mix. Pipet in 3 mL 1*N* NaOH and mix. Within 5 min, pipet in 1 mL OPT soln and mix immediately. After exactly 4 min, pipet in 3 mL 3.57*N* H<sub>3</sub>PO<sub>4</sub> and mix immediately. It is important to mix thoroughly after each addn and at least once during OPT reaction. (Run 6–10 OPT reactions simultaneously by adding reagents to erlenmeyers in set order.) Prep. blank by substituting 5 mL 0.1*N* HCl for histamine soln. Within 1.5 hr, record fluorescence intensity (*I*) of working std solns with H<sub>2</sub>O in ref. cell, using excitation wavelength of 350 nm and emission wavelength of 444 nm. Plot *I* (corrected for blank) against µg histamine/5 mL aliquot.

**18.070****Determination**

Ext prepd sample with MeOH as in 18.066, par. 1. Pass 4–5 mL H<sub>2</sub>O thru column, (a), and discard eluate. Pipet 1 mL ext onto column and add 4–5 mL H<sub>2</sub>O. *Immediately* initiate column flow into 50 mL vol. flask contg 5.00 mL 1.00*N* HCl. When liq. level is ca 2 mm above resin, add ca 5 mL H<sub>2</sub>O and let elute. Follow with H<sub>2</sub>O in larger portions until ca 35 mL has eluted. Stop column flow, dil. to vol. with H<sub>2</sub>O, stopper, and mix. Refrigerate eluate.

Pipet 5 mL eluate into 50 mL erlenmeyer, and pipet in 10 mL 0.1*N* HCl. Proceed as in 18.069, beginning "Pipet in 3 mL 1*N* NaOH . . ."

If sample contains >15 mg histamine/100 g fish, pipet 1 mL sample-OPT mixt. into 10 mL beaker contg exactly 2 mL blank-OPT mixt., and mix thoroly. Read fluorescence of new soln. Dil. and mix aliquots with blank-OPT mixt. as needed to obtain measurable reading. This approximation indicates proper diln of eluate required prior to second OPT reaction needed for reliable quantitation of sample. Alternatively, use sensitivity range control of fluorometer (if instrument has one) to est. diln. Use these approximations to prep. appropriate diln of aliquot of eluate with 0.1*N* HCl, and proceed as in 18.069, beginning "Pipet in 3 mL 1*N* NaOH . . ."

**18.071****Calculations**

Plot of *I* (measured by meter deflection or recorder response and corrected for blank) against µg histamine/5 mL soln should be straight line passing thru origin with slope =  $m = [(I_s/1.5) + I_b + 2I_c]/3$ .

$$\text{mg Histamine/100 g fish} = (10)(F)(1/m)(I_s),$$

where *I<sub>s</sub>*, *I<sub>a</sub>*, *I<sub>b</sub>*, and *I<sub>c</sub>* = fluorescence from sample, 1.5, 1.0, and 0.5 µg histamine stds, resp.; and *F* = diln factor = (mL eluate + mL 0.1*N* HCl)/mL eluate. *F* = 1 for undild eluate.

If calibration plot is not linear, use std curve directly for quantitation. Each subdivision on abscissa should be ≤0.1 µg histamine/5 mL soln. Read all values from curve to nearest 0.05 µg histamine/5 mL soln.

$$\text{mg Histamine/100 g fish} = (10)(F)(W),$$

where *W* = µg histamine/5 mL soln as detd from std curve.

**Indole****Colorimetric Method (30)—Official Final Action****18.072****Apparatus and Reagents**

(a) *Color reagent*.—Dissolve 0.4 g *p*-dimethylaminobenzaldehyde in 5 mL HOAc and mix with 92 mL H<sub>3</sub>PO<sub>4</sub> and 3 mL HCl. As purity of *p*-dimethylaminobenzaldehyde affects intensity of reagent blank, purify yellow com. reagent as follows:

Dissolve 100 g in 600 mL HCl (1+6). Add 300 mL H<sub>2</sub>O and ppt aldehyde by slowly adding 10% NaOH soln with vigorous stirring. As soon as pptd aldehyde appears white, stop addn of NaOH soln, filter, and discard ppt. Continue neutzn until practically all aldehyde is pptd, but do not carry to completion, because last 4–5 g may be colored. Filter, and wash ppt with H<sub>2</sub>O until washings are no longer acid. Dry aldehyde, which should be practically white, in desiccator.

(b) *Acetic acid, purified*.—If this reagent turns pink with color reagent, purify as follows: Add, in order specified, to 1 L r-b flask: 500 mL HOAc, 25 g KMnO<sub>4</sub>, and 20 mL H<sub>2</sub>SO<sub>4</sub>. Distil in all-glass still not >400 mL.

(c) *Dilute hydrochloric acid*.—Dil. 5 mL HCl to 100 mL with H<sub>2</sub>O.

(d) *Indole std soln*.—Accurately weigh 20 mg indole into 200

mL vol. flask and dil. to vol. with alcohol. Keep refrigerated and discard after 2 weeks.

(e) *Distillation apparatus*.—Use sep. steam generator for each unit. Steam generator may be made from 1 L erlenmeyer and connected to all-glass steam distn app. with min. use of rubber tubing. Distn flask (capacity  $\geq 500$  mL) is connected to straight bore condenser thru spray trap; 500 mL erlenmeyer is effective receiver. Foil-covered rubber stoppers may be used in absence of all-glass app. (Unprotected natural or synthetic rubber connections and stoppers cause variable distn blanks.)

Ensure absence of Cl in the  $H_2O$  which may partly or entirely inhibit development of indole color.

**18.073****Preparation of Sample**

*Crabmeat, oysters, and shrimp*.—For oyster meats weigh 50 g; for drained crabmeat or peeled raw or cooked shrimp, weigh 25 or 50 g (depending upon amt of indole expected). Transfer weighed portion to high-speed blender, add 80 mL  $H_2O$  (if oysters or crabmeat) or 80 mL alcohol (if shrimp), and mix several min until homogeneous. Quant. transfer mixt. to distn flask, and rinse mixing chamber with min. amt of same solv. used for prep g mixt.

**18.074****Determination**

Connect flask for steam distn and gently apply steam until distn is well started, using care not to pass in steam so vigorously as to cause excessive foaming. Apply enough heat to distn flask to maintain vol. of 80–90 mL. Collect 350 mL distillate in ca 45 min. (If alcohol was used in prepn of sample, collect 450 mL.) Wash condenser with small amt of alcohol and drain into receiving flask contg distillate.

Transfer distillate to 500 mL separator and add 5 mL dil. HCl and 5 mL satd  $Na_2SO_4$  soln. Ext successively with 25, 20, and 15 mL portions  $CHCl_3$ , shaking vigorously  $\geq 1$  min each time. Combine the 25 and 20 mL exts in 500 mL separator and wash with 400 mL  $H_2O$ , 5 mL satd  $Na_2SO_4$  soln, and 5 mL dil. HCl. Save wash  $H_2O$ . Filter combined exts thru cotton plug into dry 125 mL separator. Wash 15 mL portion, using same wash  $H_2O$ , and combine with other portions in same 125 mL separator.

Add 10 mL color reagent to combined exts, shake vigorously exactly 2 min, and let acid layer sep. as completely as possible. Transfer 9.0 mL acid layer to 50 mL vol. flask, dil. to vol. with HOAc, mix well, transfer soln to suitable photometer cell, and det. A at 560 nm. Color soln may be dild with HOAc contg 9.0 mL color reagent/50 mL of soln, provided blanks are detd at same dilns.

Prep. std curve as above by steam distg series of freshly prepd dilns of indole soln. Det. distn blank similarly, omitting addn of indole.

**Gas Chromatographic Method (31)—Official Final Action**

(Use reagents and materials that will not contribute P-contg compds capable of giving GLC response. Avoid plastic app. and residues of detergents and oxidg cleaning agents on glassware. Carry reagent blank thru entire method.)

**18.075****Reagents**

(a) *Carbonate buffer*.—pH ca 9.6; 0.2N each  $Na_2CO_3$  and  $NaHCO_3$ . Dissolve 21.2 g  $Na_2CO_3$  and 16.8 g  $NaHCO_3$  in  $H_2O$  and dil. to 1 L.

(b) *Indole std solns*.—(1) *Stock soln*.—1.2 mg/mL. Dissolve 120 mg indole in 100 mL EtOAc. (2) *Indole std soln I*.—12.0  $\mu$ g/mL. Pipet 1 mL stock soln into 100 mL vol. flask and dil. to vol. with EtOAc. (3) *Indole std soln II*.—6.0  $\mu$ g/mL. Pipet 25 mL std soln I into 50 mL vol. flask and dil. to vol. with EtOAc. (4)

*Indole std soln III*.—0.96  $\mu$ g/mL. Pipet 2 mL std soln I into 25 mL vol. flask and dil. to vol. with EtOAc.

(c) *2-Methylindole solns*.—(1) *Stock soln*.—1.25 mg/mL. Dissolve 125 mg 2-methylindole in 100 mL alcohol. (2) *Working soln*.—25  $\mu$ g/mL. Pipet 2 mL stock soln into 100 mL vol. flask and dil. to vol. with alcohol.

(d) *Solvents*.—Ether, anhyd., contg 0.05% alcohol, EtOAc and hexane, distd from glass.

(e) *Silica gel*.—E. Merck No. 7734 (Silica gel 60, particle size 0.063–0.20 mm).

**18.076****Apparatus**

(a) *Gas chromatograph*.—With N-sensitive detector such as thermionic flame ionization detector or Coulson conductivity detector and 1.8 m (6')  $\times$  4 mm id glass tube packed with 10% neopentyl glycol adipate (NPGA) coated on 80–100 mesh Chromosorb W (acid-washed). Operating conditions for flame detector: Temps ( $^{\circ}$ ): column 195, injection zone 220, detector 250; gas flows (mL/min): N 65 (use He for Coulson conductivity detector), air 350, H ca 25 (adjust to give standing current ca  $5 \times 10^{-10}$  amp or 30–40% recorder deflection on 5 mv recorder at electrometer sensitivity ca  $1 \times 10^{-9}$  amp full scale). Working electrometer sensitivity ca  $4 \times 10^{-10}$  amp full scale with 5 mv recorder.

(b) *GLC column*.—Dissolve 1.2 g NPGA (HI-EFF-3A, Applied Science Laboratories, Inc.) in 100 mL  $CHCl_3$  in 400 mL beaker. Add 10.8 g 80–100 mesh acid-washed Chromosorb W with stirring. Evap. solv. on steam bath with stirring. Transfer powder to rotary evaporator and remove last of solv. at 40–50 $^{\circ}$  with vac. Fill clean, dry tube, (a), with 5% soln of dimethyldichlorosilane in toluene and let stand ca 5 min. Rinse column with ca 50 mL MeOH and dry under N. (Caution: See 36.019(d).) Pack column with coated support and purge  $\geq 2$  hr with N. Condition 24 hr at 220 $^{\circ}$  with 10 mL N/min. Representative retention times are: (1) tri-*n*-butyl phosphate, 5.0 min; (2) indole, 6.8 min; (3) 3-methylindole, 8.5 min; and (4) 2-methylindole, 9.4 min. Peaks 1, 2, and 3 should be resolved at baseline; peaks 3 and 4 may overlap, but peak valley should be  $<20\%$  of peak ht.

(c) *Whatman 1PS phase separating filter paper*.

**18.077****Calibration**

Prep. calibration solns contg vols as indicated in Table 18.01. Pipet indicated vols into sep. screw-cap vials with Teflon-lined caps and mix. Store in refrigerator.

Adjust instrument to give  $\geq 10\%$  recorder deflection for 5 ng indole. Use min. injection vol. (ca 3  $\mu$ L) that gives required sensitivity. Use same injection vol. for calibration stds and samples. Make duplicate injections of each soln. Measure peak hts and calc. peak ht ratio,  $R = \text{ht indole peak}/\text{ht internal std peak}$ . Prep. std curve by plotting  $R$  against  $\mu$ g indole in std soln.

**18.078****Determination**

Weigh 25.0 g well mixed whole shrimp or 5.00 g dry shrimp and transfer to high-speed blender bowl. Add 100 mL buffer

**Table 18.01 Solutions for Calibration of Gas Chromatograph**

Calib. Soln.		Indole		2-methylindole, <sup>a</sup>	Ethyl acetate,
		Std Soln	mL	$\mu$ g	mL
1	III	2.00	1.92	1.00	0
2	II	1.00	6.00	1.00	1
3	II	2.00	12.00	1.00	0
4	I	2.00	24.00	1.00	0

<sup>a</sup> Internal std, 25  $\mu$ g/mL.

and blend 2 min at high speed. Quant. transfer slurry to 500 mL separator. Rinse blender with 25 mL H<sub>2</sub>O from squeeze bottle and add rinse to separator. Add exactly 200 mL EtOAc to separator and shake vigorously 2 min.

Let layers sep. and drain lower layer into beaker. If EtOAc (upper layer) is <150 mL, centrf. lower layer, sep., and combine resulting org. layers. Pass thru Whatman phase-sepg paper. Measure exactly 150 mL filtrate into g-s flask, and add 1.00 mL 2-methylindole working soln and 10 g anhyd. Na<sub>2</sub>SO<sub>4</sub>. Shake 1 min.

Decant ext and conc. to ca 5–10 mL, using rotary evaporator and ca 35–40° H<sub>2</sub>O bath. *Do not evap. to dryness.* (Alternatively, conc. under stream of N in 50° H<sub>2</sub>O bath.) Transfer ext to vial and conc. to ca 1–1.5 mL under N.

Prep. cleanup column by firmly placing plug of glass wool in bottom of 100 × 12 mm id glass chromatgc tube. Add 6 g silica gel and tamp firmly. Pipet ca 0.5 mL hexane on top of column. Immediately after hexane is absorbed, transfer ca 0.5 mL concd ext to column with min. disruption of packing. When level of liq. reaches top of bed, add 10 mL hexane. Similarly add 10 mL ether-hexane (1+9) and 40 mL ether-hexane (1+9). Collect all column effluent. Conc. to 0.8–1.2 mL at ≤50° under N. *Do not evap. to dryness.*

Make duplicate injections, measure peak hts, and calc. *R*. Det. / (μg indole isolated) from std curve and calc. amt indole in each sample:

$$\mu\text{g indole}/100\text{ g shrimp} = I \times 100/[g\text{ sample} \times (150/200)]$$

Calc. av. amt indole from duplicate injections.

### Paralytic Shellfish Poison

#### Biological Method (32)—Official Final Action

(*Caution:* Use rubber gloves when handling materials which may contain paralytic shellfish poison.)

#### 18.079

#### Materials

(a) *Paralytic shellfish poison std soln.*—100 μg/mL. Available from Division of Microbiology, Food and Drug Administration, 1090 Tusculum Ave, Cincinnati, OH 45226, as acidified 20% alc. soln. Std is stable indefinitely in cool place.

(b) *Paralytic shellfish poison working std soln.*—1 μg/mL. Dil. 1 mL std soln to 100 mL with H<sub>2</sub>O. Soln is stable several weeks at 3–4°.

(c) *Mice.*—Healthy mice, 19–21 g, from stock colony used for routine assays. If <19 g or >21 g, apply correction factor to obtain true death time (see Table 18.02). Do not use mice weighing >23 g and do not re-use mice.

#### 18.080

#### Standardization of Bioassay

Dil. 10 mL aliquots of 1 μg/mL std soln with 10, 15, 20, 25, and 30 mL H<sub>2</sub>O, resp., until intraperitoneal injection of 1 mL doses into few test mice causes median death time of 5–7 min. pH of dilns should be 2–4 and must not be >4.5. Test addnl dilns in 1 mL increments of H<sub>2</sub>O, e.g., if 10 mL dild with 25 mL H<sub>2</sub>O kills mice in 5–7 min, test solns dild 10 + 24 and 10 + 26.

Inject group of 10 mice with each of 2 or preferably 3 dilns that fall within median death time of 5–7 min. Give 1 mL dose to each mouse by intraperitoneal injection and det. death time as time elapsed from completion of injection to last gasping breath of mouse.

Repeat assay 1 or 2 days later, using dilns prepd above which differed by 1 mL increments of H<sub>2</sub>O. Then repeat entire test, starting with testing of dilns prepd from newly prepd working std soln.

Calc. median death time for each group of 10 mice used on

each diln. If all groups of 10 mice injected with any 1 diln gave median death time <5 or >7 min, disregard results from this diln in subsequent calcns. On other hand, if any groups of 10 mice injected with 1 diln gave median death time falling between 5 and 7 min, include all groups of 10 mice used on that diln, even though some of median death times may be <5 or >7 min. From median death time for each group of 10 mice in each of selected dilns, det. number of mouse units/mL from Sommer's Table. Divide calcd μg poison/1 mL by mouse units/1 mL to obtain conversion factor (CF value) expressing μg poison equiv. to 1 mouse unit. Calc. av. of individual CF values, and use this av. value as ref. point to check routine assays. Individual CF values may vary significantly within laboratory if technics and mice are not rigidly controlled. This situation will require continued use of working std or secondary std, depending on vol. of assay work performed.

#### 18.081

#### Use of Standard with Routine Assays of Shellfish

Check CF value periodically as follows: If shellfish products are assayed less than once a week, det. CF value on each day assays are performed by injecting 5 mice with appropriate diln of working std. If assays are made on several days during week, only 1 check need be made each week on diln of std such that median death time falls within 5–7 min. CF value thus detd should check with av. CF value within ±20%. If it does not check within this range, complete group of 10 mice by adding 5 mice to the 5 mice already injected, and inject second group of 10 mice with same diln of std. Average CF value detd for second group with that of first group. Take resulting value as new CF value. Variation of >20% represents significant change in response of mice to poison, or in technic of assay. Changes of this type require change in CF value.

Repeated checks of CF value ordinarily produce consistent results within ±20%. If wider variations are found frequently, possibility of uncontrolled or unrecognized variables in method should be investigated before proceeding with routine assays.

#### 18.082

#### Preparation of Sample

(a) *Clams, oysters, and mussels.*—Thoroughly clean outside of shellfish with fresh H<sub>2</sub>O. Open by cutting adductor muscles. Rinse inside with fresh H<sub>2</sub>O to remove sand or other foreign material. Remove meat from shell by sepg adductor muscles and tissue connecting at hinge. Do not use heat or anesthetics before opening shell, and do not cut or damage body of mollusk at this stage. Collect ca 100–150 g meats in glazed dish. As soon as possible, transfer meats to No. 10 sieve without layering, and let drain 5 min. Pick out pieces of shell and discard drainings. Grind in household-type grinder with ⅛–¼" (3–6 mm) holes or in blender until homogeneous.

(b) *Scallops.*—Sep. edible portion (adductor muscle) and apply test to this portion alone. Drain and grind as in (a).

(c) *Canned shellfish.*—Prep. by blending as in 18.012(b).

#### 18.083

#### Extraction

Weigh 100 g well mixed material into tared beaker. Add 100 mL 0.1N HCl, stir thoroly, and check pH. (pH should be <4.0, preferably ca 3.0. If necessary, adjust pH as indicated below.) Heat mixt., boil gently 5 min, and let cool to room temp. Adjust cooled mixt. to pH 2.0–4.0 (never >4.5) as detd by *BDH Universal Indicator, phenol blue, Congo red paper*, or pH meter. To lower pH, add 5N HCl dropwise with stirring; to raise pH, add 0.1N NaOH dropwise with const stirring to prevent local alkalization and consequent destruction of poison. Transfer mixt. to graduate and dil. to 200 mL.

Return mixt. to beaker, stir to homogeneity, and let settle until portion of supernate is translucent and can be decanted free of solid particles large enough to block 26-gage hypodermic needle. If necessary, centrf. mixt. or supernate 5 min at 3000 rpm or filter thru paper. Only enough liq. to perform bioassay is necessary.

**18.084****Mouse Test**

Intraperitoneally inoculate each test mouse with 1 mL acid ext. Note time of inoculation and observe mice carefully for time of death as indicated by last gasping breath. Record death time from stopwatch or clock with sweep second hand. One mouse may be used for initial detn, but 2 or 3 are preferred. If death time or median death time of several mice is <5 min, make diln to obtain death times of 5–7 min. If death time of 1 or 2 mice injected with undil sample is >7 min, total of ≥3 mice must be inoculated to establish toxicity of sample. If large dilns are

**Table 18:02 Sommer's Table**

Death time:mouse unit relations for paralytic shellfish poison (acid)

Death Time <sup>a</sup>	Mouse Units	Death Time <sup>a</sup>	Mouse Units
1:00	100	5:00	1.92
10	66.2	05	1.89

necessary, adjust pH of diln by dropwise addn of dil. HCl (0.1 or 0.01*N*) to pH 2.0–4.0 (never >4.5). Inoculate 3 mice with diln that gives death times of 5–7 min.

**18.085****Calculation of Toxicity**

Det. median death times of mice, including survivors, and from Sommer's Table det. corresponding number of mouse units. If test animals weigh <19 g or >21 g, make correction for each mouse by multiplying mouse units corresponding to death time for that mouse by wt correction factor for that mouse from Sommer's Table; then det. median mouse unit for group. (Consider death time of survivors as >60 min or equiv. to <0.875 mouse unit in calcg median.) Convert mouse units to µg poison/mL by multiplying by CF value.

$$\mu\text{g Poison}/100\text{ g meat} = (\mu\text{g/mL}) \times \text{diln factor} \times 200.$$

Consider any value >80 µg/100 g as hazardous and unsafe for human consumption.

**Identification of Fish Species****Starch Gel-Zone Electrophoresis Method (33)****Official Final Action**

(Caution: Cover for electrophoresis chamber should have switch to disconnect current to electrodes when chamber is open. Shield contacts and electrodes against body contact.)

**18.086****Apparatus**

(¼" Lucite or Plexiglas is suitable plastic for trays, cabinet, and containers; Fig. 18:04.)

(a) *Trays*.—Plastic; 20 × 250 mm, 6 mm deep, to hold starch gel.

(b) *Cabinet*.—Plastic; 7.5 × 20 × 36 cm (3 × 8 × 14") with flat cover. Make slots in rear for inserting electrodes.

(c) *Buffer and electrode containers*.—Plastic; 5 × 5 × 18 cm (2 × 2 × 7") with electrode compartment 5 × 5 × 2.5 cm (2 × 2 × 1") at one end.

(d) *Electrodes*.—18 gage Ag wire. Make tight coil at one end and insert in electrode compartment; place other end thru glass tube and attach to power supply.

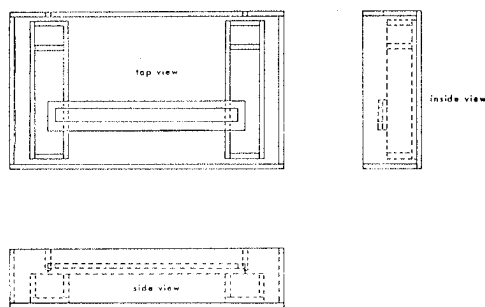

FIG. 18:04—Electrophoresis cabinet (Scale: 1" = 10")

(e) *Filter paper strips*.—Whatman No. 3; 6 × 19 mm for samples; 18 × 75 mm for connecting gel to buffer and buffer to electrode compartment.

(f) *Power supply*.—To supply const 15 ma at 190–210 volts, e.g., Heathkit or Constat.

#### 18.087

#### Reagents

(a) *Borate buffer*.—pH 8.65. Dissolve 18.5 g  $H_3BO_3$  and 4.8 g NaOH in  $H_2O$  and dil. to 1 L. Adjust with 10% NaOH soln, if necessary. Dil. 1 + 9 for prepg starch gel.

(b) *Sodium chloride soln*.—Prep. satd soln and dil. 1 + 2 for use in electrode compartment.

(c) *Hydrolyzed potato starch*.—Hydrolyze 300 g potato starch 1 hr at 40° in 600 mL acetone contg 6 mL HCl. Stop reaction by addn of 150 mL 1M NaOAc·3H<sub>2</sub>O (136 g/L) and filter with suction. Wash pptd starch with 2–3 L  $H_2O$ . Resuspend starch in 1.5 L  $H_2O$  and stir 1 hr. Refilter and wash with 2 L  $H_2O$ , and dry overnight at 50°. Grind to fine powder and test for correct gel consistency by prepg test lots contg 12, 13, 14%, etc. starch in pH 8.65 buffer, heat to just below bp, and pour into starch gel trays to cool and harden. Prep. night before use and store in refrigerator. Using known protein ext, det. starch concn giving best pattern sepn in detn. Use this concn for all detns with this batch of starch. (Prepd starch available from Fisher Scientific Co., S-676.)

(d) *5-5-1 solvent*.—Mix 5 parts  $H_2O$ , 5 parts MeOH, and 1 part HOAc.

(e) *Amido black 10B*.—1.0%. Dissolve 2 g dye in 200 mL 5-5-1 solv.

#### 18.088

#### Determination

Weigh 20–30 g minced sample into blender cup. Add 40–60 mL  $H_2O$  and blend 2 min at high speed. Pour mixt. into 50 mL centrf. tubes and centrf. at 1800 rpm until sepn is complete (10–15 min). Filter supernate thru folded Whatman No. 1 paper or on buchner with suction to obtain protein ext.

Dip small filter paper strips into protein ext and insert into starch strips by cutting starch crosswise at midpoint of length of strip. Place loaded trays in cabinet (Fig. 18:04). Place one end of large paper strip satd with pH 8.65 buffer on each end of starch tray and dip other end into tray of pH 8.65 buffer. Connect buffer compartment to electrode compartment contg dild NaCl soln with similar strip satd with the NaCl soln. Immerse Ag electrodes in both electrode compartments. Pass const 15 ma current (190–210 volts) thru system 5 hr.

Remove trays and immerse starch strips 5 min in dye soln. Return excess dye to stock soln (may be used 6–9 times). Wash dyed strips with several portions 5-5-1 solv. to remove dye from unstained portions of starch, leaving protein fractions permanently stained as blue bands.

Compare pattern with patterns of authentic materials and stds run simultaneously.

### Acrylamide Disc Electrophoresis Method (34) Official Final Action

#### 18.089

#### Apparatus

(a) *Disc electrophoresis*.—Assemble app. shown in Fig. 18:05, consisting of regulated power source (60 ma, 500 volts, DC); 2 plastic reservoirs, ca 13 cm (5") diam.; C or Pt electrodes; tube grommets (std elec. grommets); glass tubes, 65 × 5 mm id. "Top view" represents base of upper reservoir showing holes lined with rubber grommets. Gel tubes protrude from base of upper reservoir and dip into lower reservoir buffer. (See *Caution* above 18.086.) (Available as Canalc models 6, 12, 1200, 1200L from Miles Laboratories.)

Polyacrylamide gel column is composed of 3 layers: upper, large-pore (stacking) gel contg sample ions in which electrophoretic concn of ions is initiated; middle, large-pore gel (spacer gel) in which electrophoretic concn of sample ions is completed; and lower, small-pore gel in which electrophoretic sepn occurs.

Thoroughly clean and rinse app. after each detn. Wash sample tubes and soak in chromic acid cleaning soln followed by thoro rinsing with  $H_2O$ . When app. is not in use, remove buffer, 18.090(b)(7), from upper and lower reservoirs and store in sep. containers in refrigerator. Upper buffer is usually good for ca 6 detns. Discard buffer when pH drops to <8.2.

(b) *Photopolymerizing light*.—15 watt fluorescent light, 15" long.

#### 18.090

#### Reagents

(a) *Relatively stable*.—Acrylamide monomer, *N,N'*-methylenebisacrylamide (Bis), 2-amino-2-hydroxymethyl-1,3-propanediol (Tris), *N,N,N',N'*-tetramethylethylenediamine (TEMED), ammonium persulfate, riboflavin, glycine ( $NH_3$ -free), aniline black.

(b) *Relatively unstable (solns)*.—Stable ca 6 months; refrigerate solns 1–6. (1) 48 mL 1N HCl, 36.3 g Tris, 0.23 mL TEMED,  $H_2O$  to 100 mL (pH 8.8–9.0). (2) 25.6 mL 1M  $H_3PO_4$ , 5.7 g Tris, 0.46 mL TEMED,  $H_2O$  to 100 mL (pH 6.6–6.9). (3) 30.0 g acrylamide, 0.8 g Bis,  $H_2O$  to 100 mL. (4) 10.0 g acrylamide, 2.5 g Bis,  $H_2O$  to 100 mL. (5) 4.0 mg riboflavin,  $H_2O$  to 100 mL. (6) *Catalyst*.—0.14 g  $(NH_4)_2S_2O_8$ ,  $H_2O$  to 100 mL (mix fresh weekly).

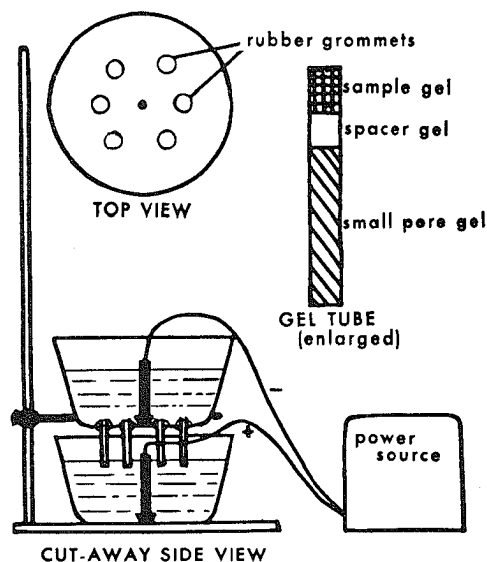

FIG. 18:05—Disc electrophoresis apparatus

(7) *Buffer*.—3.0 g Tris, 14.4 g glycine, H<sub>2</sub>O to 1 L (pH 8.8–9.0).  
 (8) *Specimen stain*.—1.0 g aniline black, 7.5% HOAc (v/v) to 200 mL.  
 (9) *Tracking dye*.—0.005% aq. bromophenol blue.

(c) *Working solns*.—Prep. fresh for each detn. (1) *Lower gel (separating gel)*.—Mix solns (b)(1), (3), and H<sub>2</sub>O (1+2+1), pH 8.8–9.0. To form gel, mix with catalyst soln, (6) (1+1). (2) *Upper gel (stacking gel)*.—Mix solns (b)(2), (4), and (5) (1+2+1), pH 6.6–6.8. To form gel, expose to fluorescent light, e.g., 18.005(b).

#### 18.091

#### Preparation of Column

(a) *Lower and spacer gels*.—Cap base of glass tube and set tube in rack. Prep. sepg gel with catalyst soln, (c)(1), in 20 mL syringe and add mixt. to tube to ca 12 mm from top. Tap tube occasionally during filling to avoid trapping air bubbles under gel surface. Place few drops tracking dye in ca 20 mL H<sub>2</sub>O and with eye dropper cautiously layer 6 mm dye soln on top of sepg gel without disturbing gel surface by touching dropper to tube edge (dye soln aids in differentiating H<sub>2</sub>O and gel layers). Discard tubes in which distinct, sharp boundary line is not visible. Let gel polymerize 30 min. (Polymerization time is based on reaction at 24°. Let refrigerated reagents stand at room temp. ca 20 min before using.) Gently shake off H<sub>2</sub>O layer and add ca 0.1 mL stacking gel soln, (c)(2), to top of column (functionally this is "spacer gel layer"). Cautiously layer 3 mm H<sub>2</sub>O atop gel. Set photopolymerizing light 7–13 cm in front of gel column rack to polymerize spacer gel in 10–15 min. Polymerization is complete when spacer gel changes from light green to translucent white. Shake off top H<sub>2</sub>O layer.

(b) *Sample gel*.—Prep. sample ext as in first par., 18.088, and mix ext, H<sub>2</sub>O, and solns, (b)(2), (4), and (5) (1+3+1+2+1) (sample stacking mixt.). If inadequate (no bands or only very faint band appears in detn), prep. new sample stacking mixt. (2+2+1+2+1).

Add 0.1 mL sample stacking mixt. to tube prepd in (a) and polymerize, using fluorescent light as in (a). Remove base cap from tube by pressing at bottom and peeling off edge to break vac. Avoid displacement of gel column from tube wall. Do not touch gel or sharp glass edge of column.

#### 18.092

#### Determination

Pour ca 500 mL buffer soln, (b)(7) (contg enough tracking dye soln to produce definite blue tinge), into lower bath or enough to cover lower electrode  $\geq 6$  mm. Insert sample end of column (top) into rubber holes in underside of upper bath until tops of glass tubes are flush with tops of rubber holes. Plug unused holes with stoppers to avoid top buffer leakage. Place upper bath over lower bath.

Slowly pour ca 250 mL buffer soln (contg tracking dye) into middle of upper bath. Fill slowly to avoid cross contamination of samples. Take extra caution to liberate all air entrapped between sample gel and buffer to permit elec. current to flow by gently introducing buffer soln into top of each sample tube, using syringe to drive out air. Set polarity of electrodes so that sample ions migrate to lower bath (pos. electrode). Turn on current and adjust power unit to give 5 ma/sample tube (5 ma  $\times$  no. of sample columns = total ma adjustment of power supply). Turn off current when "front" band is within 5 mm of bottom of sample column (ca 30–40 min).

Transfer gel column ("sample end" or "top" first) to test tube,  $\frac{2}{3}$  full with specimen stain dild with H<sub>2</sub>O (1+1), immediately after electrophoresis to stain and fix. Protein fractions in gel diffuse if not properly fixed or stained. Remove gel column from tube under H<sub>2</sub>O in pan as follows: Fill 10 or 20 mL syringe with cold H<sub>2</sub>O and insert gel-removing needle at sample end of column between glass and gel so that needle tip reaches sepg

gel. Keeping needle flat against glass surface to avoid scratching gel, rotate needle completely around circumference of gel. Remove needle and insert it from other end to depth of ca 1 cm, holding it against inner surface of glass column and at same time forcing stream of H<sub>2</sub>O thru needle. If these steps are carefully performed, entire intact gel will come free and can be slipped out of tube. If necessary, little air pressure from rubber bulb will assist in ejecting column.

While gel is being stained (above), prep. 75  $\times$  7 mm id glass destain tube as follows: Place fire polished end of tube in large diam. base cap. Add ca 1 cm sepg gel with catalyst to bottom of column and let polymerize. When staining is complete (ca 15 min), decant stain by placing lip of test tube against inside lip of beaker to retain gel in tube. Rinse twice with 7.5% HOAc (v/v) to remove excess stain. Transfer gel bottom "front" first into destain tube in which bottom plug of gel has been cast and cap removed.

Place destaining tubes in rubber holes in underside of upper bath. Plug any vacant holes. Pour ca 500 mL 7.5% HOAc in lower bath and ca 250 mL into upper bath. As previously, use syringe contg 7.5% HOAc to ensure no air bubbles exist between gel and HOAc bath. Turn on current, adjusting to 5 ma/column (5  $\times$  no. of columns = total ma). Gels will be destained in ca 45–60 min. When gel part contg no protein is clear of stain, or has pale blue color, remove specimens, and place in small test tube contg 7.5% HOAc for viewing and storage. Visually compare finished tubes with patterns prepd from authentic samples and stds run simultaneously.

#### Cellulose Acetate Strip Method (35)—Official Final Action

#### 18.093

#### Principle

Fish protein is applied to cellulose acetate supporting medium and travels when fixed voltage is applied for definite length of time. Finished strips are stained, washed, and dried to fix patterns.

#### 18.094

#### Apparatus and Reagents

(a) *Electrophoresis cabinet*.—Divided into 2 compartments (Gelman Instrument Co., 600 S Wagner Rd, Ann Arbor, MI 48106) with adjustable const voltage power supply with 300 v min. output voltage; with voltmeter which permits reading and adjusting voltage to produce desired current (Beckman Instrument Duostat power supply, or equiv.). (See *Caution* above 18.086.)

(b) *Gelman applicator*.

(c) *Cellulose acetate strips*.— $6\frac{3}{4} \times 1$ " (Gelman Instrument Co.).

(d) *Capillary tubes*.—1.6–1.8  $\times$  100 mm.

(e) *Filter paper*.—Whatman No. 1 sheets cut to convenient size.

(f) *Veronal buffer*.—pH 8.6, ionic strength 0.04; Na diethylbarbiturate 8.64 g, diethylbarbituric acid 1.2 g, and H<sub>2</sub>O to 1 L.

(g) *Stain*.—Dissolve 200 mg Ponceau S stain in 100 mL 5% trichloroacetic acid.

(h) *Wash soln*.—5% HOAc.

#### 18.095

#### Preparation of Samples

(a) *Fresh*.—Grind ca 3 g fish flesh in mortar with 3 mL H<sub>2</sub>O and squeeze through several thicknesses of cheesecloth. If centr. is available, place pieces of fish in centr. tubes and express fluid by centrfg; no added H<sub>2</sub>O is required.

(b) *Frozen*.—Thaw sample and use drip that forms undild.

(c) *Freeze-dried*.—Reconstitute samples with H<sub>2</sub>O and treat as in (a).

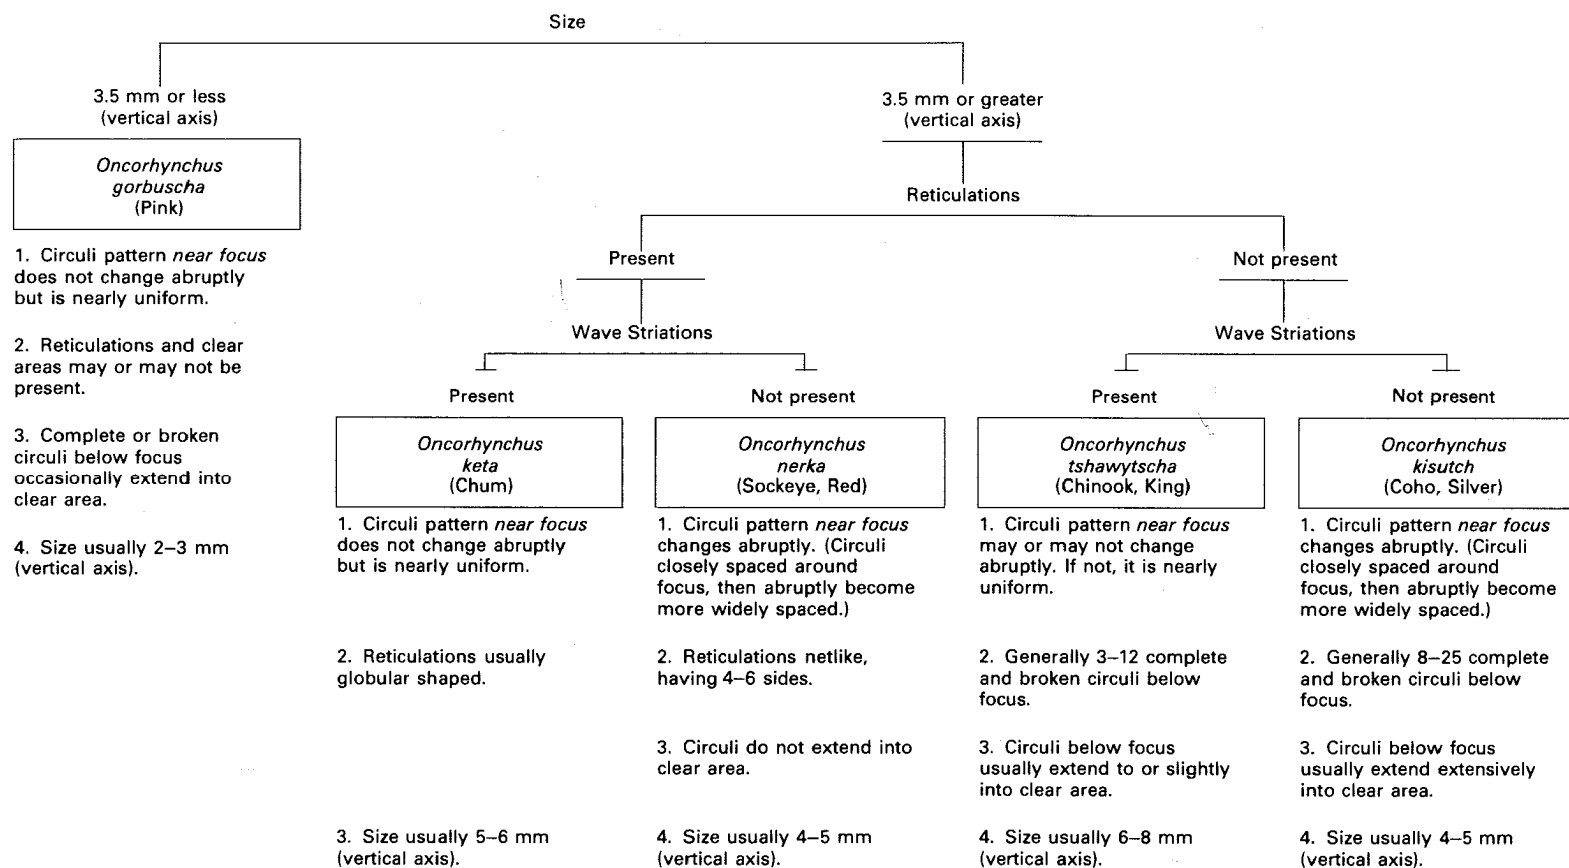

FIG. 18:06—Key to identification of canned salmon species by scale characteristics

(d) *Breaded raw sticks and portions*.—Remove breading by soaking for few sec in H<sub>2</sub>O and scraping off breading with spatula. Treat in same manner as in (b) or (a).

(e) *Precooked sticks and portions*.—Trim breading and all surface meat until internal center section remains. Treat as in (a).

#### 18.096

#### Determination

Soak cellulose polyacetate strips 30 min in buffer (soaking is required to bring strips back to original gel structure). Use new buffer supply each time. Since 6 strips can be run simultaneously, each with different sample, identify each strip with pencil notation before soaking.

Add chilled (1°C; 34°F) buffer to each chamber of cabinet and level to point slightly below compartment dividers. Remove 1 strip from buffer and gently blot between sheets of filter paper to remove excess buffer.

Take up sample of tissue fluid into capillary tube and transfer to applicator. Draw capillary tube along applicator to within 6 mm of both ends. Then press applicator firmly against strip about 5 cm from one end. Place strip contg sample across cabinet dividers so that sample is on cathode side and both ends are immersed in buffer in the 2 outer chambers. Secure acetate strips at each end with magnets or glass wedges to prevent slippage. Keep taut. Repeat sample application with each strip, working quickly to prevent strips from drying out.

Put cabinet cover in place, connect electrodes, and set power supply to give const voltage. Adjust voltage (between 200 and 300 v) to produce initial current of 1.5 ma/strip. Maintain this voltage 30 min. Shut off power supply, remove strips from cabinet, and place in Ponceau S stain 5 min. Immerse strips in series of 3 rinsing solns of 5% HOAc to remove excess dye. Rinse strips until only protein bands are left stained and remainder of strip is free from dye. Finally, blot strips and dry between several sheets of filter paper. Compare protein patterns of samples with those of authentic flesh samples.

#### Identification of Canned Pacific Salmon (36)—Official First Action

#### 18.097

#### Apparatus and Reagent

(a) *Microscopes*.—(1) Wide-field; and (2) compd, with variable iris diaphragm.

(b) *Glycerol jelly*.—To 60 mL H<sub>2</sub>O add 5 g gelatin and heat gently until completely dissolved. Add 40 mL glycerol and 0.5 g phenol, and mix. Cool and store in closed container at room temp.

#### 18.098

#### Method

Empty entire contents of can into pan. Remove as much skin as possible from meat with aid of spatula and place skin in petri dish. Keep skin surface moist with H<sub>2</sub>O at all times; if skin is allowed to dry, scales will curl, become brittle, and be unsuitable for mounting. Examine skin under wide-field microscope, using ca 10× magnification. Scales generally will be inside folds of skin (scale pockets) with portion of one end of scale protruding from pocket. Scan entire surface of all skin, and select largest and most nearly intact scales available. This is very important; if size difference is seen on same piece of skin, larger scales will have the most intact clear areas, and also internal scale pattern will be more complete.

Gently insert thin-tipped spatula well underneath whole scale between bottom side of exposed portion of scale and skin.

Completely fold back this entire portion to make whole scale visible. Again, gently insert spatula between scale and skin and remove scale with back-and-forth motion. While keeping scale moist with H<sub>2</sub>O, rub very gently with small tool, such as artist's brush, to remove any adhering skin or foreign material. Place small amt glycerol jelly on microscope slide and melt by placing slide on heat source. Pick up scale with spatula and remove any excess H<sub>2</sub>O by touching gently to towel. Place scale in jelly and cover with cover glass. If scale curls during mounting, invert, uncurl, and cover quickly. Examine under compd microscope at 25–50×, using transmitted light. Adjust light intensity for optimum contrast of scale patterns.

Examine whole scales with intact clear areas, avoiding undeveloped, distorted, or damaged scales. Intact clear area must be present for accurate identification (except pink salmon). Det. salmon species by using key in Fig. 18:06 and by comparing to scales in Figs. 18:07–11 with pertinent features noted. Examine sufficient no. of scales to ensure pos. identification.

*Precautions*.—Use only scales that contain distinct wave striations and reticulations for comparison with key and photographs.

Scale patterns of coho and chinook species are somewhat similar. Circuli extending into clear area (coho), and wave striations in clear area (chinook) can be mistaken for each other. Note differences in Fig. 18:08 and 18:09. Chinook scales may have only few striations. Follow key (Fig. 18:06) carefully.

Chum and sockeye scales are both reticulated, but sizes and shapes of this feature differ. Under low (30×) power, chum reticulations appear globular, or like small round air bubbles; in sockeye they are netlike, 4–6 sided, and larger.

When pink salmon scales occur with reticulations and intact clear area, they may be differentiated from sockeye by their length. Vertical axis of pink is ≤3.5 mm; of sockeye, >3.5.

Relative size of scales (as length of vertical axis) is important in identification of all 5 species: chinook and chum have largest scales (7 and 6 mm, resp.), coho and sockeye scales are 4–5 mm, and pink salmon scales (easily recognized by their small size) are ≤3.5 mm.

Disregard scales which are damaged, have hard rib-like structure, or are distorted (all circuli surrounding focus are completely missing with this void extending about half way to scale edge).

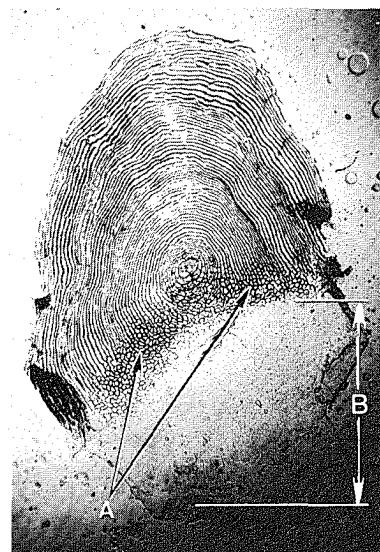

FIG. 18:07—Sockeye (red) salmon scale (*Oncorhynchus nerka*), 10×: A, Reticulations: Net-like divisions at junction of circuli and clear area; B, Clear area.

FIG. 18:08—Chinook (King) salmon scale (*Oncorhynchus tshawytscha*), 10×: A, focus (the area within first circulus). B, Wave striations (irregularly shaped nearly horizontal wavy lines in clear area).

FIG. 18:10—Chum salmon scale (*Oncorhynchus keta*), 10×: A, wave striations (irregularly shaped nearly horizontal wavy lines in clear area).

Note: For chum and chinook as in above photo.

Wave striations are not connected to and are not in line with concentric rings of circuli and should not be confused with circuli.

For chum and pink as in above photo.

Circuli pattern (near focus) does not change abruptly but is nearly uniform.

FIG. 18:09—Coho (silver) salmon scale (*Oncorhynchus kisutch*), 10×: A, Circuli (concentric rings).

Note: For coho and pink as in above photo.

When circuli are present in clear area they extend from concentric pattern to form complete circle; if broken they are still in line of curvature of concentric ring.

For coho and sockeye as in above photo.

Circuli pattern (near focus) changes abruptly. Circuli closely spaced around focus, then abruptly become more widely spaced.

FIG. 18:11—Pink salmon scale (*Oncorhynchus gorbuscha*), 10×.

(Left) Pink scale with clear area mostly absent.

(Right) Pink scale with clear area present. Note broken circuli near focus extending into clear area.

# 19. Flavors

## ALCOHOL

### Gas Chromatographic Method (1) Official First Action

19.001

#### Apparatus and Reagents

(a) *Gas chromatograph*.—With flame ionization detector (F&M Model 400, 402, Hewlett-Packard 7600 series, or equiv.). Column 1.2 m (4') × 2 mm id glass packed with 100–120 mesh Chromosorb 102; column temp. 160° (isothermal), detector and inlet 200°; He flow rate 50 mL/min; relative retention times: EtOH 1.00 (≤100 sec), *n*-PrOH 2.06, and tetrahydrofuran 3.04.

(b) *Integrator*.—Hewlett-Packard 3370A (new model 3370B), or equiv.

(c) *Alcohol std solns*.—Dil. 5, 10, 15, and 20 mL absolute alcohol at 60°F (15.56°C) to 100 mL with H<sub>2</sub>O, adjusting final vol. at 60°F, to prep. 5, 10, 15, and 20% solns.

19.002

#### Determination

Pipet 25 mL of each EtOH std soln into sep. flasks or bottles and add 1.00 mL *n*-PrOH internal std. Cap immediately with rubber stoppers, shake 3 min, and let stand 10 min at room temp. Inject 0.1 μL portions from 1 μL microsyringe. Det. peak areas with integrator, calc. ratio (*R*) of areas of EtOH to *n*-PrOH, and plot % EtOH as abscissa against *R* as ordinate. Slope should be 0.195±0.006.

Perform detn on sample as above but shake 10 min. If sample contains >20% EtOH, pipet 5 mL sample, 20 mL tetrahydrofuran (Fisher Scientific Co.), and 1 mL *n*-PrOH into flask or bottle. Analyze ≥1 std EtOH-*n*-PrOH soln daily as check on performance.

$$\% \text{ EtOH} = (\text{EtOH peak area} / n\text{-PrOH peak area}) \times (1.00 / \text{slope}) \times F,$$

where *F* = 1 for undild samples and 5 for dild samples.

## VANILLA EXTRACT AND ITS SUBSTITUTES

### 19.003 Specific Gravity—Official Final Action

Det. sp gr at 20/20° with pycnometer as in 9.011.

### 19.004 Alcohol—Official Final Action

Proceed as in 9.013 or 9.021, but measure sample at 15.56° in pycnometer, Fig. 9.01, calibrated at that temp.

### 19.005 ★ Glycerol—Official Final Action ★

Proceed as in 11.010★, 12th ed., or 11.011★, 12th ed., selecting method according to amt of sugar present. Use sample contg 0.1–0.4 g glycerol.

### Propylene Glycol (2)—Official Final Action

19.006

#### Apparatus

All-glass distn app. with 24/40 joints: 250 mL erlenmeyer, 20 mL Barrett H<sub>2</sub>O trap with stopcock, and West condenser with drip tip.

19.007

#### Reagents

(a) *Heptane*.—Eastman Kodak Co. practical grade, bp 96–100°, or equiv.

(b) *Potassium arsenite std soln*.—0.02*N*. (Caution: See 51.078 and 51.084.) Dissolve 4.9460 g reagent As<sub>2</sub>O<sub>3</sub>, pulverized and dried to const wt at 100°, in 75 mL 1*N* KOH. Add 40 g KHCO<sub>3</sub>, dissolved in ca 200 mL H<sub>2</sub>O, and dil. with H<sub>2</sub>O to 1 L at 25°. Dil. 200 mL of this soln to 1 L with H<sub>2</sub>O.

(c) *Potassium periodate std soln*.—0.02*M*. Dissolve 4.6 g KIO<sub>4</sub> in ca 500 mL hot H<sub>2</sub>O. Dil. to ca 900 mL with H<sub>2</sub>O, cool to room temp., and dil. to 1 L. Stdze frequently, since this soln decomposes on standing.

(d) *Bromocresol purple indicator soln*.—Dissolve 0.1 g indicator in 100 mL alcohol and filter if necessary.

(e) *Propylene glycol*.—Reagent grade or com. product that meets following test: Dil. 0.5 mL to 25 mL with H<sub>2</sub>O, add 25 mL 0.02*M* KIO<sub>4</sub> soln, and let stand 10 min. Titr. with 0.02*N* NaOH, using 3 drops bromocresol purple. Vol. NaOH soln consumed minus end point correction obtained by titrg 50 mL H<sub>2</sub>O should be ≤0.1 mL.

19.008

#### Isolation of Propylene Glycol

Place sample contg ca 1 g propylene glycol in 250 mL erlenmeyer; add enough H<sub>2</sub>O, if necessary, to make total vol. 10 mL. Add 60 mL heptane, few glass beads, and/or SiC grains. Connect flask to receiver attached to condenser. Fill receiver with heptane, heat flask with variable heat hot plate, and reflux at such rate that rapid stream of distillate flows from tip. Reflux ca 8 hr and cool.

Open stopcock of receiver and transfer aq. layer to 250 mL (or other convenient size) vol. flask. Wash condenser, receiver, and solv. layer by pouring six 10 mL portions H<sub>2</sub>O down condenser, collecting each portion in receiver, and draining it into vol. flask. Finally wash with enough H<sub>2</sub>O (ca 25 mL) to completely fill receiver, causing solv. layer to return to distn flask. Dil. to vol. and mix well.

19.009

#### Determination

(a) *Glycerol absent*.—Place aliquot of aq. soln contg ≤45 mg propylene glycol in g-s flask, add 35 mL 0.02*M* KIO<sub>4</sub> soln, dil. to ca 100 mL with H<sub>2</sub>O, and let stand 1 hr. Add ca 1.0 g NaHCO<sub>3</sub>, 0.5 g KI, and 2.5 mL starch indicator, 2.144(b). Titr. with 0.02*N* KAsO<sub>2</sub> soln to disappearance of blue. Stdze 25 mL 0.02*M* KIO<sub>4</sub> soln by same titrn, using H<sub>2</sub>O for sample, and calc. amt of KIO<sub>4</sub> reduced by sample. 1 mL 0.02*N* KAsO<sub>2</sub> = 0.76 mg propylene glycol.

(b) *Glycerol present*.—Proceed as in (a). If I is not liberated on addn of NaHCO<sub>3</sub> and KI, insufficient KIO<sub>4</sub> was present. Repeat detn, using smaller aliquot or increasing vol. of KIO<sub>4</sub> soln.

To det. glycerol in the aq. soln, place same vol. aliquot used above in g-s flask, add 1 drop bromocresol purple, and add 0.02*N* NaOH until soln is light purple. Add same vol. KIO<sub>4</sub> soln used above, dil. to ca 100 mL, and let stand 1 hr. Add 10 drops propylene glycol (ca 0.5 mL), mix well, wash down sides of flask with H<sub>2</sub>O, and let stand 10 min. Add 3 drops indicator and titr. with 0.02*N* NaOH to light purple end point. Titr. rapidly but do not shake flask vigorously in order to avoid excessive absorption of interfering CO<sub>2</sub> from air. Det. blank for this detn as above, using H<sub>2</sub>O in place of sample and omitting 1 hr standing. Subtract blank from titrn obtained for sample aliquot. 1 mL 0.02*N* KAsO<sub>2</sub> = 0.46 mg glycerol; 1 mL 0.02*N* NaOH = 1.84 mg glycerol.

$$\text{mg Propylene glycol in aliquot} = [\text{mL } 0.02\text{N KAsO}_2 - (4 \times \text{mL } 0.02\text{N NaOH})] \times 0.76$$

★ Surplus method—see inside front cover.

**Vanillin****19.010 Ultraviolet Screening Method (3)  
Official Final Action**

(Caution: See 51.016.)

(In absence of coumarin and Et vanillin.  
Make all readings  $\leq 2$  hr of final diln.)

Pipet 5 mL sample (for imitations and concs, use 2 mL) into 100 mL vol. flask, dil. to vol. with  $H_2O$ , and mix well. Pipet 2 mL of this soln into second 100 mL vol. flask, add 2 mL 0.1*N* NaOH, and dil. to vol. with  $H_2O$ . Pour ca 20 mL of this soln into small beaker and place under UV lamp in dark room. If coumarin is present to extent of 0.01% in original ext, brilliant green fluorescence will develop in 5 min.

If no coumarin is observed, read *A* of remaining alk. soln at 270, 348, and 380 nm. Obtain background  $A = 0.29A_{270} + 0.71A_{380}$ . Subtract this value from  $A_{348}$  and divide by  $A'$  of 1 ppm vanillin (ca 0.150), detd from std soln of 3 ppm vanillin, and multiply by diln (1000) to give ppm vanillin in original sample.

Prep. 3 ppm std vanillin soln by dissolving 0.1000 g vanillin in 3 mL alcohol in 100 mL vol. flask, and dilg to vol. with  $H_2O$  (1 mL = 1 mg). Pipet 3 mL into 1 L vol. flask, add 2 mL 0.1*N* NaOH, and dil. to vol. with  $H_2O$ . Calc. corrected  $A'$  as above. Divide this value by 3 to obtain corrected  $A'$  of 1 ppm vanillin.

If background *A* is too high ( $>0.15$ ), clarify with isopropanol as follows:

Pipet 5 mL sample into 50 mL vol. flask and dil. to vol. with isopropanol. Transfer to centrf. bottle and centrf. ca 10 min at high speed. Without disturbing sepd solids, carefully pipet 1 mL liq. into 100 mL vol. flask, add 2 mL 0.1*N* NaOH, dil. to vol. with  $H_2O$ , and proceed as above.

**Ultraviolet Spectrophotometric Method (4)  
Official Final Action****19.011 Preparation of Standard Curve**

Dissolve 0.100 g vanillin in 5 mL alcohol and dil. to 100 mL with  $H_2O$ . Transfer 15, 10, and 5 mL, resp., to 250 mL vol. flask, dil. to vol. with  $H_2O$ , and mix (*Solns X*). Pipet 10 mL of each *Soln X* into 100 mL vol. flask, dil. to vol. with  $H_2O$ , and mix. Pipet another set of 10 mL *Solns X* into 100 mL vol. flasks, add ca 80 mL  $H_2O$  and 2 mL 0.1*N* NaOH, mix, dil. to vol. with  $H_2O$ , and mix again. Obtain *A* of alk. solns at 348 nm, using neut. solns as ref. blanks. Plot std curve.

**19.012 Determination**

If sample contains  $>0.3$  g vanillin/100 mL, dil. with 35% alcohol to below this level. Pipet 10 mL sample (or dild sample) into 100 mL vol. flask, dil. to vol. with  $H_2O$ , and mix. Pipet 2 mL dild soln into each of two 100 mL vol. flasks, dil. one to vol. with  $H_2O$ , and mix. To other flask add 80 mL  $H_2O$  and 2 mL 0.1*N* NaOH, mix, dil. to vol. with  $H_2O$ , and mix again. Det. *A* of alk. soln at 348 nm, using neut. soln as ref. blank. Obtain vanillin content from std curve.

**Vanillin and Ethyl Vanillin (5)  
Official Final Action****19.013 Reagents and Apparatus**

(a) *Mobile solvent*.—Cyclohexane (practical)-EtOAc-MeOH (100+30+20).

(b) *Immobile solvent*.—10% Dimethylformamide (DMF) in ether.

(c) *Sodium carbonate soln*.—Dissolve 4 g  $Na_2CO_3$  in  $H_2O$  and dil. to 1 L.

(d) *Chromatographic paper*.—Whatman No. 3MM, 8 × 8".

(e) *Chromatographic tank*.—Mitchell tank and equipment, 29.007(a).

(f) *Spotting pipet*.—10  $\mu$ L.

(g) *Longwave ultraviolet light*.—(Caution: See 51.016.)

**19.014 Preparation of Standard Curve**

Prep. solns of vanillin and Et vanillin in 35% alcohol contg 0.10, 0.15, 0.20, 0.30, and 0.40 g/100 mL. Draw parallel lines on chromatgc paper 2.5 and 3.7 cm above bottom edge, using hard pencil. Apply one 10  $\mu$ L spot of each soln on the 2.5 cm line, keeping spots 2.5 cm apart and starting 5 cm from left side of paper. Use sep. papers for vanillin and Et vanillin curves. Use same micropipet for all spottings, rinsing thoroly before each application. Let spots air dry, without heat. Handle paper carefully near edges to avoid high blanks.

Meanwhile place 100 mL  $H_2O$  in bottom of chromatgc tank contg one trough. Fill trough with mobile soln., cover tank, and seal. Let stand 15 min. Dip paper into immobile solv. from top down to 3.7 cm line, leaving bottom 3.7 cm of paper free from immobile solv. Do not permit solv. to reach spots. (Dipping can readily be done by use of shallow pan contg solv.) Air dry paper few min, remove seal from tank, and place paper in tank with bottom edge dipping into mobile solv. Reseal tank and develop 2 hr, even tho solv. front reaches top before end of this period. Remove paper and air dry. Do not expose developed paper to air  $>1$  hr. If delay is necessary, place paper in jar and store in refrigerator.

Expose paper to  $NH_3$  fumes for few min by placing paper in wide-mouth half-gal. (2 L) jar contg small beaker with  $NH_3$  on bottom, and capping jar. Examine paper under longwave UV light and outline dark blue areas with soft pencil. Et vanillin will show higher *R<sub>f</sub>* value than vanillin. Remove marked areas with scissors and cut each into smaller pieces before placing them in 50 mL erlenmeyers. Cut out 2 blanks from side of paper, each approx. equal in area to developed spots. Use side area for these blanks, away from spotted areas and their developed rise.

Pipet 10 mL  $Na_2CO_3$  soln into each flask, swirl, and let stand 10–15 min, with frequent swirling. Centrf. or filter thru rapid paper, discarding first portion of filtrate. Det. *A* at 348 nm, using  $Na_2CO_3$  soln as ref. Also obtain av. *A* of the 2 blanks and subtract from std *A* before plotting std curve.

**19.015 Determination**

If sample contains  $>0.4$  g vanillin/100 mL, dil. below this level with 35% alcohol. Make one 10  $\mu$ L spotting on the 2.5 cm line with same micropipet used to prep. std curves. Proceed as above and det. vanillin and Et vanillin by comparison with appropriate std curves.

**Coumarin—Official Final Action****19.016 ★ Photometric Method (6) ★**

See 19.009–19.011, 10th ed. (Caution: See 51.068.)

**Vanillin, Ethyl Vanillin, and Coumarin (7)  
Official Final Action****Chromatographic Separation Method****19.017 Apparatus**

(a) *Spectrophotometer*.—Capable of detg *A* at 270 and 325 nm. Adjust to high sensitivity to utilize slit width  $<10$  nm.

(b) *Silica cells*.—1 cm. Match cells at 270 and 325 nm, using

★ Surplus method—see inside front cover.

isooctane- $\text{CHCl}_3$  solv., **19.018(c)**. (This solv. det. differences that other media do not.) Cells must be free of other solvs before adding isooctane- $\text{CHCl}_3$  solv., std, and sample solns. Drain each cell well between readings by inverting on towel. Fill cells for reading so that meniscus is  $>3$  mm above light path.

(c) *Chromatographic tube*.—14 mm od  $\times$  450.

**19.018****Reagents**

(Same batch of isooctane must be used to prep. solv. mixt. and all dilns for set of detns.)

(a) *Silicic acid*.—Reagent grade "100-mesh" powder, suitable for chromatgy (Mallinckrodt Chemical Works No. 2847, or equiv.). Det.  $\text{SiO}_2$  content as follows: Accurately weigh ca 1 g silicic acid into weighed Pt crucible. Ignite in furnace 15 min at  $615^\circ$ , cool in desiccator, and reweigh. Calc. %  $\text{SiO}_2$  (z) in silicic acid. Calc. wt silicic acid (x) required for 5.8 g column as:  $x = 3.384 \times 100/z$ . Vol. (mL)  $\text{H}_2\text{O}$  (y) required for column is  $5.80 - x$ .

(b) *Isooctane*.—Practical grade 2,2,4-trimethylpentane, 99.5+%, bp  $98-100^\circ$ .

(c) *Isooctane-chloroform solvent mixture*.—Add 40 mL  $\text{CHCl}_3$  to 1 L isooctane and mix. Store in airtight bottle. (Do not use rubber stopper.) Soln contains ca 3.85%  $\text{CHCl}_3$ .

(d) *Coumarin std soln*.—1 mg/mL. Accurately weigh 100 mg coumarin into 100 mL vol. flask, dissolve in 50 mL  $\text{CHCl}_3$ , and dil. to vol. with isooctane.

(e) *Ethyl vanillin std soln*.—Prep. as in (d), using Et vanillin.

(f) *Vanillin std soln*.—Prep. as in (d), using vanillin.

**19.019****Determination of Absorptivities**

Pipet 1 mL vanillin std soln into 100 mL vol. flask, add 3.4 mL  $\text{CHCl}_3$ , dil. to vol. with isooctane, and mix. Det. A at 270 and 325 nm against solv., (c), as ref. in the 1 cm silica cells. Calc. a (g/L; 1 cm) for vanillin at 270 and at 325 nm as:  $a = 100A$ .

Det. a for Et vanillin and vanillin similarly.

**19.020****Preparation of Chromatographic Column**

Pack small cotton wad in bottom of dry chromatgc tube. To x g silicic acid in mortar add y mL  $\text{H}_2\text{O}$  from buret, mix thoroly and quickly to uniform powdery consistency with pestle, and immediately add 25 mL solv., (c). Mix and rapidly pour slurry thru funnel into tube. Rinse mortar and funnel with small vol. solv. Remove any air bubbles formed by stirring with long thin glass rod. Pack column with ca 13.8 kPa (2 lb/sq in.; 10.4 cm Hg) air pressure until bottom of meniscus of free solv. just touches top surface of silicic acid but outer part of meniscus is still clearly visible. *Immediately release pressure*. (Important: If column channels or cracks, discard. During packing and thereafter, keep column vertical. Tipping ruins column for further use altho it may appear normal.) Carefully add 15 mL solv. down side of tube with aid of glass rod so column is not disturbed. Drive solv. thru column. Washed column is now ready for calibration.

**19.021****Calibration of Column**

Pipet and combine 1 mL of each std soln, (d), (e), and (f), in 25 mL vol. flask. Dil. to vol. with isooctane and mix. Pipet 2 mL soln down one side of chromatgc tube onto top of column. Drive soln into column with ca 2 lb/sq in. (10.4 cm Hg) air pressure and collect eluate in 10 mL graduate. Release pressure when bottom of meniscus touches top of column and outer part of meniscus is still clearly visible. Pipet 1 mL solv., (c), down same side of tube onto column and drive into column. Repeat with 2 addnl 1 mL portions solv. Fill tube to within 2 cm of top with

solv. Drive solv. thru column at rate of 5 mL/2–2.5 min, collecting 5 mL eluate fractions, alternating two 10 mL graduates during collection. Pour fractions into sep. test tubes in rack, numbering fractions consecutively. Drain graduate before reusing by inverting on towel. Collect 10 fractions and det. A at 270 and 325 nm against solv., (c), as ref. in 1 cm silica cells. Drain cells by inverting on towel before refilling; rinsing is not necessary. Permit column to elute by gravity while reading first 10 fractions, changing graduates for each 5 mL portion.

Coumarin elutes first, Et vanillin second, and vanillin third. In ideal column coumarin begins to elute in fraction 6–7, reaches max. in 8–9, and fades considerably in 10. Earlier elution does not sep. compds entirely; later elution takes more fractions and time but does give good recoveries. Somewhat slower elution does not matter. Et vanillin elutes in ca fraction 11–18, and vanillin in ca 19–30.

If column is satisfactory, collect 25 addnl fractions (35 in all) or until vanillin is completely eluted. Det. A of each fraction at 270 and 325 nm as above.

If coumarin begins to elute at fraction 5 or earlier, discard, prep. another column with less  $\text{H}_2\text{O}$  in the silicic acid, and recalibrate. If coumarin does not elute by fraction 9–10, prep. new column with more  $\text{H}_2\text{O}$  in the silicic acid.

Use calibrated column for identification, **19.023**

**19.022****Preparation of Sample Solution**

If concn of none of the compds is  $>0.4$  g/100 mL, pipet 25 mL sample into 250 mL centr. bottle. If concn of any compd is  $>0.4$  g/100 mL, dil. 25 mL sample with  $\text{H}_2\text{O}$  to vol. specified in Table **19.01**, and use 25 mL aliquot. Add 75 mL  $\text{H}_2\text{O}$ , 20 mL  $\text{H}_2\text{SO}_4$  (1+4), and 50 mL  $\text{CHCl}_3$ . Stopper with rubber stopper and shake well 3 min. Centr. 5 min at 1500 rpm. If emulsion persists, break with thin glass rod and recentrf. Pour contents slowly thru large-bore, short-stem funnel into 250 mL separator. Break emulsion with glass rod and drain  $\text{CHCl}_3$  into 100 mL vol. flask. Pour aq. phase thru same funnel back into bottle.

Rinse separator with 15 mL  $\text{CHCl}_3$ , add to bottle thru funnel, and repeat extn by mixing phases thoroly with rocking motion. Do not shake vigorously as in first extn. Centr., sep., and drain  $\text{CHCl}_3$  into 100 mL vol. flask. Repeat extn with 15 mL portions  $\text{CHCl}_3$  until flask is filled to mark. Pipet 2 mL aliquot into 25 mL vol. flask, dil. to vol. with isooctane, and mix.

**19.023****Identification**

Pipet 2 mL sample soln (use 1 mL if concn of most abundant compd is  $>3.2$  g/100 mL) onto prepd column, letting it flow down one side of tube without disturbing column. Drive soln into column with ca 2 lb/sq in. (10.4 cm Hg) air pressure and collect eluate in 10 mL graduate. Pipet 1 mL solv., (c), down same side of tube and drive into column. Repeat with 2 addnl 1 mL portions of solv. Fill tube with solv. and elute compds by same technic and conditions as for calibration. Collect 3 more fractions than indicated necessary by calibration. Det. A of all fractions at 270 and 325 nm as in calibration.

Positions of absorbing fractions compared to those obtained during column calibration reveal compds present in sample.

**Table 19.01 Dilutions and Dilution Factors for Flavorings**

Concn of Most Abundant Constituent, g/100 mL	Dil. to: (mL)	Diln Factor (F)
$<0.4$	none	12.5
0.4–0.8	50	25.0
0.8–1.6	100	50.0
1.6–3.2	200	100
$>3.2$	400	200

**Table 19:02 Spectrophotometric Characteristics of Coumarin, Ethyl Vanillin, and Vanillin**

Coumarin	Ethyl Vanillin	Vanillin
Maxima, nm		
271 (1.00)	270 (1.00)	269.5 (1.00)
282 (0.82)	297 (0.59)	296 (0.60)
313 (0.46)	—	—
Minima, nm		
243 (0.30)	242.5 (0.24)	242.5 (0.24)
278.5 (0.81)	286 (0.46)	286 (0.48)
291.5 (0.31)	—	—

Coumarin is also identified by absorbing at 325 nm slightly  $>1/3$  its  $A$  at 270 nm. Vanillin and Et vanillin absorb very little at 325 nm. If desired, confirm by obtaining UV spectrum of one high absorbing fraction of each compd. Compare with spectra prep'd on same instrument. Spectra of compds exhibit approx. max. and min. given in Table 19:02. Approx. ratio of  $A$  at given wavelength to that at highest max. for respective compd is given in parentheses after that wavelength. Ratio of 1.00 indicates highest max.

**19.024****Determination**

Add  $A$  at 270 nm of all fractions contg coumarin and calc. coumarin concn in original sample:

$$c = F \times \Sigma A/a,$$

where  $\Sigma A$  is sum of  $A$  at 270 nm of fractions contg coumarin,  $a$  is absorptivity of coumarin at 270 nm,  $c$  is concn coumarin in g/100 mL original sample, and  $F$  is diln factor, given in Table 19:01.

Calc. concns of Et vanillin and vanillin similarly.

If neg.  $A$  are obtained on fractions not contg the compds, correct  $A$  of fractions contg compds by adding to each  $A$  the av. of the neg. readings.

**Lead Number (Wichmann) (8)**  
**Official Final Action**

**19.025****Principle**

Org. acids from vanilla are pptd with neut.  $Pb(OAc)_2$  under std conditions, insol.  $Pb$  salts are removed, and excess  $Pb$  is detd by chelometric titrn with  $Na_2EDTA$ . From this titrn and blank titrn, Wichmann lead number is calcd. Applicable to single-fold exts.

**19.026****Reagents**

(a) *Disodium ethylenediamine tetraacetate* ( $Na_2EDTA$ ) std soln.—0.025*N*. Dissolve 9.3061 g  $Na_2EDTA \cdot 2H_2O$  in 1 L boiled, cooled  $CO_2$ -free  $H_2O$ .

(b) *Buffer soln.*—Mix 2 vols 0.1*N*  $NaOAc$  with 1 vol. 0.1*N*  $HOAc$ .

(c) *Xylenol orange soln.*—Dissolve 0.1 g xylenol orange in 100 mL 35% alcohol.

(d) *Lead acetate soln.*—Dissolve 8 g neut.  $Pb(OAc)_2$  in 100 mL boiled  $H_2O$ , let stand 24 hr, and use clear supernate.

(e) *Phenolphthalein soln.*—Dissolve 0.1 g phthln in 100 mL alcohol.

**19.027****Preparation of Sample Solution**

Place 175 mL boiled  $H_2O$  in 1 L r-b distn flask. From pipet add 25 mL clear  $Pb(OAc)_2$  soln and 50 mL single-fold ext. Swirl to mix thoroly and ppt  $Pb$  salt. Support distg flask on asbestos or transite board, placing flask over 10 cm diam. hole cut in board to permit distn without overheating upper portion of flask. Fit

with distn head and condenser, apply moderate heat, and distil 200 mL into vol. flask, reserving distillate for detn of alcohol. When vol. in distn flask is reduced to ca 50 mL, level of liq. should be approx. even with board. Quant. transfer residue to 100 mL vol. flask with small vols  $CO_2$ -free  $H_2O$ , using bent glass rod with rubber tip to loosen residue. Cool, and dil. to vol. with  $CO_2$ -free  $H_2O$ . Mix thoroly and filter thru dry paper. Filtrate (*Soln X*) contains excess  $Pb$  after forming  $Pb$  salt complex.

Prep. blank, using 5 drops  $HOAc$  in place of sample and distil 150 mL. Cool, dil. to 100 mL with boiled  $H_2O$ , and filter.

**19.028****Determination of Lead**

(a) *As sulfate.*—Pipet 10 mL *Soln X* into 250 mL beaker and add 25 mL  $H_2O$ , 2 mL  $H_2SO_4$  (1+1), and 100 mL alcohol; stir and let settle overnight. Filter on gooch, wash with alcohol, ignite at 525–550°, cool in desiccator, and weigh. (Wt  $PbSO_4$  obtained from blank – wt obtained from sample)  $\times 13.66$  =  $Pb$  number.

(b) *As chromate.*—Pipet 10 mL *Soln X* into 400 mL beaker and add 2 mL  $HOAc$ , 25 mL  $H_2O$ , and 25 mL ca 0.1*N*  $K_2Cr_2O_7$ . Heat immediately with moderate flame until ppt changes from yellow to orange. Filter on gooch, and wash thoroly with hot  $H_2O$ , then with few mL each of alcohol and ether. Dry at 100°, cool in desiccator, and weigh. (Wt  $PbCrO_4$  obtained from blank – wt obtained from sample)  $\times 12.82$  =  $Pb$  number.

(c) *By chelometric titration.*—Pipet 10 mL *Soln X* into 125 mL erlenmeyer. Add 1 drop phthln and make just alk. with 1.0*N*  $NaOH$ , pptg  $Pb(OH)_2$ . Add 10 mL buffer soln and 1 mL xylenol orange indicator. Titr. with 0.025*N*  $Na_2EDTA$  soln to end point, indicated by abrupt change from reddish pink to yellow or orange. Ten mL microburet is convenient for titrn, and fluorescent lamp should be arranged so indirect light illuminates flask.

Perform titrn on blank soln in same manner.

Lead number =  $20 \times (\text{mL } Na_2EDTA \text{ blank} - \text{mL } Na_2EDTA \text{ sample}) \times 0.025 \times (207.2/1000) = (\text{mL } Na_2EDTA \text{ blank} - \text{mL } Na_2EDTA \text{ sample}) \times 0.1036$ .

**19.029 Total Solids (9)—Official Final Action**

Proceed as in 31.007 or 31.008, using 10 mL sample.

**19.030 Ash—Official Final Action**

Evap. 10 mL ext and proceed as in 31.012 or 31.013.

**19.031 Sucrose (10)—Official Final Action**

See 31.025, 31.026, or 31.031.

**Vanilla Resins**

**19.032 Quantitative Method (11)**  
**Official Final Action**

Pipet 50 mL sample into 150 or 250 mL beaker and dil. to 100 mL with  $H_2O$ . Boil rapidly on hot plate or over flame to ca 50 mL. Cool, and add  $NH_4OH$  (1+3) dropwise until slightly alk. Add 3 drops excess and stir vigorously 2 min to ensure soln of resins. Add  $HCl$  (1+1) dropwise, with stirring, until acid to indicator paper and then 2 mL excess. Stir, and let stand at room temp.  $\geq 1$  hr but  $\leq 24$  hr. Add 0.5 g filter-aid (Celite, Hyflo Super-Cel) and filter with suction thru long stem, medium porosity, 30 mL, fritted glass buchner funnel contg pad prep'd by pouring aq. suspension of 1 g filter-aid thru funnel and washing with  $H_2O$ . If filtration slows, gently scratch surface of pad to break resin film. Quant. transfer resins to funnel with aid of policeman, using six 20 mL portions 0.05*N*  $HCl$  to wash beaker and funnel. Let each portion of wash soln drain before adding next. Dry material as much as possible by suction, transfer funnel to dry

suction flask, and dissolve resins from filter with boiling alcohol added in small portions, using some of alcohol to rinse beaker. Suck each portion thru funnel before adding next. Mix filter-aid in funnel with the hot alcohol, using small glass rod. Repeat extns until alcohol soln is colorless. Rinse tip of funnel stem with hot alcohol and quant. transfer soln to weighed beaker or Pt dish. Evap. to dryness on steam bath and dry 1 hr at 100°. Cool in desiccator and weigh. Report results to 2 decimal places only. Reserve resins for qual. tests.

#### 19.033 *Paper Chromatographic Qualitative Test (12)—Official First Action*

Sep. and dissolve resins in warm alcohol as in 19.032, collecting alc. ext in 50 mL vol. flask. Cool, and dil. to vol. with alcohol. Evap. 40 mL aliquot to dryness on steam bath and dry to const wt at 100° to obtain mg resins/mL alc. ext. (Alternatively, use *value* obtained from 19.032. Do not use dried resins obtained from 19.032 for this detn.) Evap. 5 mL aliquot of alc. ext nearly to dryness on steam bath and complete drying with aid of gentle heat such as warm air current from hair dryer. Dissolve residue in calcd vol. of 0.1N NaOH in 50% alcohol to give soln of 5 mg resins/mL.

Spot 6  $\mu$ L alk. soln (using two 3  $\mu$ L spottings with intervening drying) on 8  $\times$  8" paper as in 19.039(a). Develop as in 19.040, using solv. systems 19.037(a) or (b). On same paper spot alk. soln of alc. ext of resins from authentic vanilla ext, 19.038, at same concn, 5 mg/mL. Compare developed patterns under longwave UV light.

#### 19.034 *Methanol—Official First Action*

Proceed as in 9.089 or 9.090, using distillate from alcohol detn, 19.004.

#### 19.035 *Color Insoluble in Amyl Alcohol (13) Official First Action*

Evap. 25 mL sample just to dryness on steam bath. Dissolve residue in H<sub>2</sub>O and alcohol, and dil. to 50 mL, using total vol. of 26.3 mL alcohol. Place 25 mL of this soln in separator and add 25 mL freshly shaken Marsh reagent, 9.094, shaking gently so as not to form emulsion. Let layers sep. completely, drain aq. lower layer (which contains any caramel present) into 25 mL graduate, and dil. to vol. with alcohol (50% by vol.). Compare this soln in colorimeter with 25 mL untreated sample. From this reading, calc. % color insol. in amyl alcohol.

### Foreign Plant Material

#### *Paper Chromatographic Method (14) Official Final Action*

#### 19.036

#### *Apparatus*

(a) *Chromatographic chamber for small papers.*—See 29.007(a).

(b) *Chromatographic chamber for large papers.*—Use box suitable for this size paper chromatgy. A satisfactory box is ca 29.5  $\times$  21.5  $\times$  23.75" (75  $\times$  55  $\times$  60 cm) covered with Formica or other material resistant to org. solvs, acid, alkali, etc. Lid of box is hinged and plastic gasket is used to obtain tight seal to prevent escape of vapors. Front of box contains window 11  $\times$  17" (28  $\times$  43 cm) to observe progress of solv. front. Semicircular glass troughs ca 26.5  $\times$  2" (67  $\times$  5 cm) are supported by stainless steel clamps on metal strips ca 2" (5 cm) wide placed 2.5" (6 cm) from top and extending from front to back along sides. Clamps also support glass rods on both sides of trough and parallel to it.

(c) *Chromatographic papers.*—Whatman No. 1, 8  $\times$  8"; Whatman No. 1, 22  $\times$  18"; Whatman No. 3MM, 8  $\times$  8".

(d) *Ultraviolet light.*—Long wavelength. Two 15 watt Black Light tubes, 18" long, preferably enclosed in glass filters (such as No. 5873 tubular glass filters, George W. Gates & Co., Hempstead Tnpg & Lucille Ave, Franklin Sq., NY 11010). (*Caution:* See 51.016.)

#### 19.037

#### *Solvent Systems*

(a) Dissolve 20 g KOH and 50 g KBr in H<sub>2</sub>O, add 200 mL alcohol, and dil. to 1 L with H<sub>2</sub>O.

(b) Dissolve 20 g KHCO<sub>3</sub> and 50 g KBr in H<sub>2</sub>O, add 200 mL alcohol, and dil. to 1 L with H<sub>2</sub>O.

(c) Shake 20 parts isobutanol, 0.8 part HOAc, and 15 parts H<sub>2</sub>O in separator, let sep., and drain and discard lower layer. Use upper layer.

(d) Mix 8 parts isopropanol, 5 parts NH<sub>4</sub>OH, and 15 parts H<sub>2</sub>O.

(e) Mix 30 parts HOAc, 3 parts HCl, and 10 parts H<sub>2</sub>O.

(f) Dissolve 20 g KHCO<sub>3</sub> in H<sub>2</sub>O, add 200 mL alcohol, and dil. to 1 L with H<sub>2</sub>O.

(g) Mix 75 parts isopropanol with 25 parts H<sub>2</sub>O.

#### 19.038

#### *Preparation of Authentic Vanilla Extract*

Prep. single-fold authentic vanilla ext with and without added sugar by either NF or Flavoring Extract Manufacturers Association (FEMA) method. Prep. concs by evapg single-fold ext under vac. in rotary evaporator and dilg with 50% alcohol to appropriate vol.

(a) *NF method.*—Cut 100 g vanilla beans in small pieces, add 200 mL H<sub>2</sub>O, and macerate 12 hr in covered container, preferably in warm place. Add 200 mL alcohol, mix well, and macerate ca 3 days. Transfer mixt. to percolator contg 200 g coarse granular sucrose (omit sucrose for prepn without sucrose) and drain. Pack solids firmly and percolate slowly with alcohol (1+1) to obtain total vol. of 1 L.

(b) *FEMA method* (Proc. 40th Flavoring Extract Manufacturers Association Convention 1949, pp. 49–67 (as revised)).—(Boil all rubber stoppers in 5% NaOH soln and use Tygon tubing for connections.) Prep. laboratory continuous percolator as follows:

Fit 2-hole rubber stopper into neck of custom-made Pyrex gas washing bottle made from No. 2962 cylinder, 4.5 od  $\times$  12" long (11.4  $\times$  30.5 cm), plain neck opening ca 3" (7.6 cm) diam., with coarse porosity fritted glass disk sealed in as close to bottom as possible but above side arm, 9 mm od, extending out from side wall between disk and base (available from Corning Glass Works or H. S. Martin Co., 1916 Greenleaf St, Evanston, IL 60204). Thru one hole place 0–220°F (–20–110°C) thermometer with bulb at ca center of bottle; thru other hole insert short piece of glass tubing so that end is 2.5 cm above level of chopped vanilla beans. Attach piece of 100 mesh stainless steel wire cloth tied with cord to end of tubing in bottle as strainer and attach other end to Fischer & Porter Co. Flowrator Meter, Model 10A 1017A (tube ¼" to meter liq., sp gr 0.96, 700 mL/min max., direct reading scale, stainless steel float). Attach upper end of flowmeter with right-angle bend tube to side arm of T-tube with upper end connected with Tygon tubing to glass tube in 1-gal. (3.8 L) jar fitted with 2-hole rubber stopper. Other hole of stopper holds glass tube fitted with Bunsen valve (rubber tube, closed at one end, with short longitudinal slit) as safety valve. Place gal. jar above rest of equipment (serves as overflow reservoir when percolator runs overnight).

Attach lower end of T-tube thru Y-tube and 1-hole rubber stoppers to 2 Pyrex buchners (connected in parallel) with coarse porosity fritted disks (80 mm diam., Corning No. 36060-C). Place

circles of Whatman 41H paper on disks, and cover with 3 mm clean sand. Place stems of funnels thru rubber stoppers inserted in filter tubes (Corning No. 9480, 32 × 160 mm). Tubes are connected in parallel with Tygon tubing to Y-tube connected to menstruum reservoir (Corning No. 1220, 2 L aspirator bottle) with 45° bend glass tube thru 2-hole rubber stopper. Thru second hole, fit stem of thermoregulator (No. 17502-0, stainless steel, Fenwal, Inc., PO Box 309, Ashland, MA 01701) which controls 200 watt mantle fitted to reservoir. Connect mantle to thermoregulator thru relay. Connect outlet of bottle to inlet of stainless steel pump with nipple connections (Model B 1, 1/20 h.p., LFE Corp., Fluids Control Div., 100 Skiff St, Hamden, CT 06514, or equiv.). Control flow rate by pinch clamp on tubing from discharge side of pump to bean reservoir, to give flow rate of 575 mL/min. Set thermoregulator so thermometer reads 120°F (49°C).

Cut vanilla beans into 3 mm pieces with razor blade, or preferably shred in Model D Fitzpatrick Comminuter, or equiv., using No. 4 screen (The Fitzpatrick Co., 832 Industrial Dr, Elmhurst, IL 60126). Place 10 oz (280 g) dry wt cut beans (calcd from moisture detn) in extractor, and place several 8 cm, 90° bends of glass rod on surface to keep beans submerged. Place dild alcohol (1136 g alcohol plus 1090 g H<sub>2</sub>O) in reservoir. Percolate ≥16 hr and remove 25 mL sample for alcohol detn, **19.004**. Calc. g H<sub>2</sub>O to add to give 47.5% alcohol (= 2790 - 132414/% alcohol), add this amt to reservoir, and continue percolation at least addnl 24 hr.

Drain ext from both reservoirs and remove 25 mL sample for alcohol detn. Det. vol. remaining ext, and calc. vol. H<sub>2</sub>O needed to adjust to 35% alcohol. If desired, add sugar equiv. to 10%, det. final vol., and dil. to 35% alcohol with H<sub>2</sub>O.

**19.039****Preparation of Papers**

(a) *For 8 × 8" papers, single dimension development.*—Use Whatman No. 1 for ext with little or no sugar, and No. 3MM for ext with considerable sugar. Apply no more than 7 samples, including authentic, to single paper. Spot samples equal distance apart. For single strength exts apply four 3 μL spots at same point, drying between applications with hair dryer, IR lamp, or other source of mild heat. Do not apply next spot until previous one is dry. For concd exts, dil. to 4-fold concn with 50% alcohol and apply one 3 μL spot.

For products contg large amts of sugar, ext 1 mL with 1 mL CHCl<sub>3</sub>, centr., and spot CHCl<sub>3</sub> ext as above. Compare with authentic ext treated similarly. (JAOAC **44**, 549(1961).)

(b) *For 22 × 18" papers, single dimension development.*—For single strength exts, apply four 10 μL spots at same point with intervening drying as in (a). For concd exts, dil. to 4-fold concn with 50% alcohol and apply one 10 μL spot.

(c) *For 8 × 8" papers, two dimension development.*—Use Whatman No. 3MM paper. Apply four 3 μL spots of single strength vanilla ext sample at lower right side of 8 × 8" paper and eight 3 μL spots at lower left side, locating each spot ca 2.5 cm from outer edges of paper. Apply each set of spots at same point, drying between applications with warm air dryer or other source of mild heat. Do not apply next spot until previous one is dry.

**19.040****Development**

(a) *Single dimension.*—Use ascending technic with small papers and descending technic with large papers. Use solvs (a), (b), (c), (d), or (e), listed in approx. order of usefulness. Develop small papers 2–3 hr and large papers 12–16 hr until solv. approaches end of paper. Remove papers from tank and let air dry. Examine under transmitted UV light and compare fluores-

cent pattern of spots from samples with those from authentic material.

It is sometimes useful to return dry paper to original solv. and repeat development. Second development may cause greater sepn of some fluorescent constituents.

(b) *Two dimension.*—Transfer papers, prepd as in **19.039(c)**, to tank, and develop first dimension with solv. (f) and ascending technic. Remove paper when solv. front reaches upper edge, and air dry. Turn paper 90° so that 24 μL spot is at bottom; then develop second dimension in solv. (g). Remove paper before front reaches developed 12 μL spot, and air dry. Examine paper under longwave UV light, and compare chromatogram with one made from authentic vanilla ext. Foreign plant material is indicated by spots not found in authentic ext.

**Flavoring Additives****Thin Layer Chromatographic Method (15)  
Official Final Action****19.041****Apparatus**

(a) *Applicator.*—For depositing thin layer on glass plates.

(b) *Glass plates.*—8 × 8" or 2 × 8"; of uniform thickness.

(c) *Plastic board.*—22 × 113 cm, with retaining edges 1.8 cm wide along short and long sides.

(d) *Developing jars or tanks.*—Use equipment, **29.007(a)**, for 8 × 8" glass plates and glass cylinders for small plates. Cylinders can be covered with plastic caps.

**19.042****Reagents**

(a) *Solvents.*—Hexane (99%)-EtOAc (4+1); benzene-MeOH (97+3).

(b) *Chromogenic agents.*—(1) Mix 90 mL 0.1N KMnO<sub>4</sub> and 10 mL 0.1N NaOH. (2) Sat. 1N HCl with N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>SO<sub>4</sub>. (3) 5% KOH in MeOH. (4) 10% phosphomolybdic acid in alcohol.

(c) *Silica Gel G.*—Fine grade silica gel with added plaster of Paris. Check ability to make satisfactory sepn by testing activated plates with known mixts of additives.

**19.043****Test**

Place glass plates on plastic board held on laboratory bench so that long edge faces worker and short retaining ledge is on right. Mix 30 g Silica Gel G in beaker with 60 mL H<sub>2</sub>O, stirring thoroly ca 1 min. Slurry must be uniform and free from air bubbles. Pour into applicator, which is on glass plate at left side of board. Make film 0.250 mm thick by slowly moving applicator across row of plates. Total time from addn of H<sub>2</sub>O to silica gel until end of spreading operation must be ca 4 min. Air dry plates 10–20 min and then dry 2 hr at 110° to activate layers. Cool, wipe backs and edges of plates free from excess silica gel, and store plates in storage cabinet. Protect from laboratory fumes.

Scratch line across a plate 17 cm from bottom edge and apply 10 μL spot of single-fold sample 2 cm from bottom edge. Spots should be ca 0.5 cm in diam. (It may be necessary to apply small portion at time, drying between applications.) Different samples can be spotted 2 cm apart. Apply ref. stds similarly. Place plate in jar or tank so that bottom edge dips 1 cm into solv. and lean top of plate against side of jar or tank, so that plate has slight angle. Cover tank or jar and let develop to 17 cm scratch line. Remove from solv. and air dry.

All additives, if present in sufficient amt, can be detected by KMnO<sub>4</sub> spray. Tan spots appear on pink background, which soon turns brown. Second spraying helps bring out spots. Small amts of coumarin may not show up for several min, so that it is necessary to examine plate ca 10 min after spraying.

Yellow spots are shown by *p*-hydroxybenzaldehyde, vanillin, Et vanillin, veratraldehyde, and piperonal when plates are sprayed with  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{SO}_4$  soln. Let air dry and examine under reflected UV light (longwave). *p*-Hydroxybenzaldehyde usually shows up as lemon-yellow spot, vanillin and Et vanillin appear orange to brown, veratraldehyde is bright orange, and piperonal is bluish-yellow. Shades depend on amts of additive present and amt of spray, and may vary somewhat.

To detect coumarin, spray with alc. KOH, and let air dry. Examine under reflected UV light; coumarin appears as bright blue-white spot.

Vanitrope can be detected by spraying with phosphomolybdic acid soln. Blue spot develops after plate is dried at 100° few min.

Approx.  $R_f$  values, with vanillin = 1, are: Hexane-EtOAc solv.: Et vanillin, 1.6; veratraldehyde, 1.7; coumarin, 2.3; piperonal, 3.0; and vanitrope, 4.0. Benzene-MeOH solv.: *p*-hydroxybenzaldehyde, 0.4; Et vanillin, 1.4; coumarin, 1.7; veratraldehyde, 1.9; piperonal, 2.4; and vanitrope, 2.4.

*p*-Hydroxybenzaldehyde is difficult to detect with hexane-EtOAc solv. since vanillin spot is near origin. With this solv., Et vanillin and veratraldehyde cannot usually be sepd. *p*-Hydroxybenzaldehyde can be detected with benzene-MeOH solv., and Et vanillin and veratraldehyde show good sepn, but piperonal and vanitrope appear at same  $R_f$  value. These can be distinguished by phosphomolybdic acid and  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{SO}_4$  tests on sep. plates.

### Organic Acids

#### Paper Chromatographic Sorting Method (16)

##### 19.044

##### Apparatus

(a) *Chromatographic tank*.—For ascending chromatography with 12 × 12" sheets; cylindrical glass jar with ground top and glass plate cover, or rectangular jar with tight lid. Use smallest jar that will hold paper. (Neoprene gasket may be used to ensure tight fit.)

(b) *Chromatographic paper*.—Whatman No. 1, 12 × 12".

##### 19.045

##### Reagents

(a) *Developing soln.*—Ether- $\text{HCOOH}\cdot\text{H}_2\text{O}$  (20+4+3). If necessary, add  $\text{HCOOH}$  in small amts until soln is clear.

(b) *Chromogenic agents*.—(1) *Aniline-furfural*.—Dissolve 0.3 mL aniline and 0.3 mL furfural in 100 mL acetone. Use as dip. Hang paper in air until spots are fully developed (red spots on pink background). For spray use, replace acetone with MeOH. (2) *Aniline-xylose*.—Dissolve 1 g xylose in 3 mL  $\text{H}_2\text{O}$ , add 57 mL MeOH, and mix. Add 1.0 mL aniline and 40 mL acetone, and mix. (Dip or spray.) Hang paper in air 5 min to let excess solv. evap.; then place in oven 10 min at 105° (stable brown spots on tan background). (3) *pH indicators*: (a) Dissolve 0.02 g bromocresol purple in 10 mL alcohol and dil. to 100 mL with acetone. Add  $\text{NH}_4\text{OH}$  dropwise until soln is red by transmitted light. Use as dip, and air dry. Repeat until best contrast is obtained. If used as spray, replace acetone with alcohol. (b) Dissolve 0.02 g bromocresol green in 10 mL alcohol and dil. to 100 mL with acetone. Add 1*N* NaOH until soln is blue-green by transmitted light. Use as dip. For spray use, replace acetone with alcohol.

##### 19.046

##### Determination

(Caution: See 51.059.)

Place 10 mL single strength vanilla ext, or equiv. of concd ext dild to 10 mL with 35% alcohol, in 50 mL centr. tube and add 25 mL alcohol. Mix, add 2.5 mL  $\text{Pb}(\text{OAc})_2$  soln (8 g/100 mL), mix thoroly, and centr. Decant clear supernate. Wash residue twice

with 10 mL portions 80% alcohol, mixing well each time and discarding clear wash. Disperse ppt in 10 mL  $\text{H}_2\text{O}$  (no lumps) and pass in  $\text{H}_2\text{S}$  5 min. Filter thru small rapid paper into beaker and wash ppt twice with small portions  $\text{H}_2\text{O}$  satd with  $\text{H}_2\text{S}$ . Mix ppt well with each wash to break up all large clumps. (Filtrate should be clear.) Evap. nearly to dryness on steam bath, using air jet if desired. Complete drying carefully and remove from heat as soon as dry. Cool, and take up with exactly 1 mL  $\text{H}_2\text{O}$ , warming gently if necessary.

Spot 12  $\mu\text{L}$  soln on 12 × 12" paper, 2.5 cm from bottom and 4 cm from side edge, by applying four 3  $\mu\text{L}$  portions at same place and drying between applications with warm air. Spot different samples 4 cm apart. Hang paper in rectangular jar with lower end dipping 1 cm into solv. If cylindrical jars are used, roll paper and connect edges slightly apart (use stainless steel clips or cotton thread to connect). If small jars are not available, equilibrate by adding large excess of solv. to larger jars and let stand overnight before inserting paper. (Line larger jars with blotting paper with lower edge immersed in solv.) Cover jars with weighted covers or seal with tape. Develop, preferably at 20–23°, until front is 2.5 cm from top (ca 6 hr; spottings can be made in afternoon and development started early next day).

Air dry overnight. To ensure complete removal of  $\text{HCOOH}$ , steam paper, without wetting, by rolling and inserting into 15 cm stove-pipe section with bottom over rapid source of steam (paper must not touch sides). Steam 15 min, remove, and air dry. Treat with one of chromogenic agents, (b), by dipping or spraying ((b)(1) preferred for initial tests). Mark spots with pencil, indicating weak and strong spots, and compare pattern with authentic vanilla org. acid sample treated simultaneously. Note position, size, and intensity of acid spots. Vanilla ext org. acid chromatogram will show 4 strong spots and several weak ones.

#### Derivative Gas-Liquid Chromatographic Method (17)—Official Final Action

##### 19.047

##### Apparatus

(a) *Vials*.—5 mL, with screw caps provided with Teflon liners. (Other plastic or metal liners are not satisfactory.)

(b) *Gas chromatograph*.—Varian Aerograph Model 1520, dual column, and thermal conductivity detectors, at 225° and 200 ma (or equiv.). Operating conditions: 1.8 m (6') × 1/4" stainless steel column packed with 3.8% SE-30 on 60–80 mesh Diatoport S (silanized) (Varian Associates, 611 Hansen Way, Palo Alto, CA 94303), programmed at 6°/min, from 75 to 210°; injector temp. 225°; He gas flow 40 mL/min; sample injection 5  $\mu\text{L}$ ; attenuation, to give 50% chart width response to internal std.

Other equipment may be used with following conditions: thermal conductivity detector temp. 225–275°; injection port temp. 200–300°; programming rate 6–10°/min; He flow 40–60 mL/min; sample injection 5–25  $\mu\text{L}$ . (Flame ionization detectors may also be used, with proper adjustment of sample size and sensitivity.)

##### 19.048

##### Reagents

(Note: Tri-Sil reagent and pyridine may be harmful. Caution: Protect skin and eyes when using. Use effective fume removal device.)

(a) *Neutral lead acetate soln.*—Dissolve 8 g  $\text{Pb}(\text{OAc})_2\cdot 3\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 100 mL with  $\text{H}_2\text{O}$ .

(b) *Internal std soln.*—Dissolve 0.100 g glutaric acid in 80% alcohol and dil. to 100 mL with 80% alcohol. Store in tightly closed bottle.

(c) *Tri-Sil reagent*.—Pyridine soln of trimethylchlorosilane (TMS) and hexamethyldisilazane (10+1+2) (available as Tri-Sil 48999, Pierce Chemical Co.). Use to prep. TMS derivatives.

## 19.049

**Determination**

Transfer 2.0 mL single-strength vanilla ext to 15 mL screw-cap centr. tube, and add ca 0.2 g Celite 545 and exactly 1.0 mL internal std soln. Mix, and add 0.7 mL Pb(OAc)<sub>2</sub> soln; mix again, and add 5.0 mL alcohol. Cap tube, mix, and centr. at moderate speed until ppt is well packed and supernate is clear. Discard supernate, add 5.0 mL 80% alcohol to ppt, mix, and centr. again. Discard clear supernate and repeat washings twice more, using 5.0 mL alcohol for first wash and 5.0 mL ether for second. Each time mix thoroly, cap, centr., and discard clear supernate. Drain ether for few min; then place tube in 50–55° H<sub>2</sub>O bath. Stir residue with stainless steel wire until most of ether is removed and solid material in tube appears dry and powdery. Brush any powder adhering to wire into tube and place open tube in 100° oven 1 hr. Remove tube from oven, cool somewhat, add 3 pieces of *Drierite*, and cap tightly. Inject 1.5 mL Tri-Sil reagent into cool tube from 2 mL syringe, recap, and mix thoroly, making sure that all residue in tube is wet with pyridine soln. Place tube in 37° oven 1 hr, with occasional mixing. Centr. and decant clear supernate into dry 5 mL vial contg several pieces of *Drierite*. Cap tightly with Teflon-lined screw cap.

Inject sample into gas chromatograph and program as in 19.047(b). Compare sample curve with curves of authentic vanilla exts obtained under same conditions. Authentic vanilla exts show many peaks, with 8 major ones. Internal std appears between peaks 1 and 2. Peak 7 is always highest peak in pure vanilla samples. Sum of 8 peak hts, calcd on basis of internal std peak ht = 1.00, provides useful information on amt of vanilla acids present. Ratio peak 2:peak 7 also provides significant information. Note also presence or absence of foreign peaks. If some peaks are too high for measurement, repeat detn with greater attenuation.

(Note: TMS derivatives tend to break down with heat, and continued use may impair column efficiency. Also, artifacts occur sometimes, particularly on first run of day. Columns usually can be reconditioned by overnight heating at 250° with slow stream of He. Disconnect column from detector when performing such reconditioning. Special regenerating liqs (e.g., Silyl-8, Pierce Chemical Co.) are also available for injection into columns used for TMS work. Heating thermal conductivity detectors at higher temps, without current, helps keep them free from decomposition products.)

**Direct Gas Chromatographic Method (18)**  
**Official Final Action**

## 19.050

**Gas Chromatograph**

Use gas chromatograph with thermal conductivity or flame ionization detector. Temps: Program column from 70 to 250° at 4°/min, injector 240°, detector 240°. Columns: 6 m × 1/8" stainless steel or Cu, packed with 3% silicone oil (SE-30, SF-96, OV-1, or OV-101) on silanized 100–120 mesh Chromosorb W, acid-washed and dichlorodimethylsilane-treated, or Gas-Chrom Q; He carrier gas flow 30–35 mL/min. Alternatively, use 1.8 m × 1/4" column with same packing material at flow rate of 60–80 mL/min.

## 19.051

**Reagents**

(a) *2-Methyl butane (isopentane)*.—Bp 27.5–28.5° (less pure grades may be purified by passing thru silica gel and distg). Reagent blanks should show no peaks in test. (Caution: See 51.011 and 51.039. Isopentane is very flammable. Evap. in fume hood away from sparks and open flame.)

(b) *Internal std.*—0.2% hexadecane in absolute alcohol.

## 19.052

**Determination**

Place 100 mL single-fold vanilla ext (dil. stronger exts with 35% alcohol to single-fold) in 250 mL separator or g-s cylinder, add 0.5 mL internal std and 40 mL isopentane, and gently invert 10–15 times. Vigorous agitation may result in emulsions. Let layers sep. and transfer clear upper layer to dry flask. Remove upper layer by aspiration or by decantation from separator after draining lower colored layer. Repeat extn twice with 40 mL isopentane. Add 1 g anhyd. Na<sub>2</sub>SO<sub>4</sub> to flask, shake, and decant soln thru small glass wool plug into beaker. Rinse flask with small amt solv.

Evap. carefully on warm H<sub>2</sub>O bath under hood until solv. is reduced to ca 5 mL. (Caution: See 19.051(a).) Transfer to 15 mL graduated centr. tube with small amts solv., add small boiling chip, and immerse tube in warm H<sub>2</sub>O to remove solv. When solv. is reduced to 0.5 mL, transfer tube to beaker contg acetone and ice, and let vanillin ppt. When upper layer is clear, transfer this soln to small container with Teflon cap or liner, using syringe or glass tube drawn out to capillary tip at one end. If desired, this soln can be further concd to ca 0.2 mL. Chromatograph as soon as possible after concg. Do not let conc. remain overnight before chromatgy.

Inject into chromatograph, using cooled syringe to avoid premature volatilization of solv. Sample size depends on sensitivity of instrument; use ca 2 µL with flame ionization and 10–15 µL with thermal conductivity detector. Adjust instrument to obtain ca 50% deflection with internal std, which shows peak shortly after vanillin peak. Use pure vanilla ext samples as comparison stds. Added aromatics over 10 ppm will be detected as foreign peaks.

**LEMON, ORANGE, AND LIME**  
**EXTRACTS AND FLAVORS**

19.053 **Specific Gravity—Official Final Action**

Det. sp gr at 20/20° with pycnometer as in 9.011.

**Alcohol**19.054 **Specific Gravity Method (19)**  
**Official Final Action**

(Applicable to exts consisting only of oil, alcohol, and water)

Det. sp gr at 15.56/15.56° or at 20/20° as in 9.011 and oil content as in 19.065, 19.066, or 19.126, and apply following formula: Let *S* represent sp gr of sample; *O*, sp gr of oil; and *p*, % oil found. Then  $(100 - p) = \% \text{ H}_2\text{O-alcohol soln, sp gr of which, represented by } P, \text{ is:}$

$$S = [Op + P(100 - p)]/100;$$

therefore

$$P = (100S - Op)/(100 - p).$$

Det. *E*, alcohol equiv. of *P*, from 52.003. It gives % alcohol in alcohol-H<sub>2</sub>O soln. To find % alcohol in ext, apply following formula:

$$\% \text{ by vol. of alcohol in ext} = E[1 - (p/100)].$$

Value of *O* for lemon oil may be taken as 0.86 and for orange oil as 0.85.

19.055 **Gas Chromatographic Method**  
**Official First Action**

See 19.001–19.002.

**19.056 ★ Methanol—Official Final Action ★**

See 19.047, 10th ed.

**Isopropanol—Official Final Action****Applicable to Lemon Extract in Absence of Acetone (20)****19.057 Preparation of Sample**

Place sample contg  $\leq 8$  g total alcohols (approximation of alc. content may be made from sp gr detn and ref. to 52.003), into separator in stem of which is cotton pledget wet with  $H_2O$ . Add 25 mL 10% NaCl soln and 25 mL pet ether. Shake well, let layers sep., and drain lower layer into flask. Repeat extn with 3 addnl 25 mL portions NaCl soln or until alcohol is completely extd. Add  $H_2O$  to combined aq. exts until vol. is ca 150 mL. Connect flask to vertical condenser and distil into 100 mL vol. flask, removing flask when distillate is 2–3 mL below mark. Dil. to vol. and mix.

**19.058 Qualitative Test for Acetone**

To 2 mL distillate add 0.5 mL 5% alc. *o*-nitrobenzaldehyde soln and 1 mL 10% NaOH soln. Mix; then shake with small vol.  $CHCl_3$ . If  $CHCl_3$  turns blue, acetone is present.

**19.059 Determination**

Pipet 10 mL distillate into 500 mL erlenmeyer contg 50 mL ca 2N  $K_2Cr_2O_7$  and add 100 mL  $H_2SO_4$  (1+3). Stopper flask, swirl, and let stand 30 min. Add 100 mL 30%  $FeSO_4 \cdot 7H_2O$  soln. Connect flask to vertical condenser thru foam trap. Slowly distil ca 100 mL into 500 mL vol. flask contg 200–300 mL cold  $H_2O$ . Dil. to vol., mix, and pipet 25 mL into g-s flask contg 25 mL 1N NaOH; add 50 mL stdzd 0.1N I with swirling. Let stand 15 min. Add 26 mL 1N HCl and at once titr. residual I with stdzd 0.1N  $Na_2S_2O_3$ , adding starch soln when I color is nearly discharged. Each mL 0.1N I consumed in reaction = 1.001 mg isopropanol.

**Applicable to Lemon and Orange Flavors in Presence of Acetone (21)****19.060 Apparatus**

**Glassware.**—Use foil-wrapped stoppers or preferably all-glass still. Provide condenser with adapter which reaches several inches into vol. flask.

**19.061 Preparation of Sample**

Proceed as in 19.057, placing 100 mL vol. flask in ice- $H_2O$  bath.

**19.062 Determination of Acetone**

Pipet aliquot preferably contg 0.1–0.3 g acetone into 100 mL vol. flask and dil. to vol. with  $H_2O$ . Det.  $A$  at 265 nm with  $H_2O$  as ref. soln in Beckman Model DU (current model 24/25) spectrophtr, or equiv. Correct for  $A$  of  $H_2O$  in same cell as used for sample, if necessary. Det. amt of acetone in the 100 mL vol. flask by ref. to std curve prepd from redistd acetone.

In absence of purified acetone, g acetone/100 mL may be estd as  $C = A/3.08$ , where  $C =$  g acetone/100 mL,  $A =$  corrected  $A$  in 1 cm cell, and 3.08 = assumed  $A$  of 1 g/100 mL soln of acetone in 1 cm cell. Calc. to g acetone/100 mL sample.

**19.063 Determination of Isopropanol**

Proceed as in 19.059, distg ca 100 mL into 250 mL vol. flask contg ca 100 mL cold  $H_2O$  and held in ice- $H_2O$  bath. Dil. to vol.

with  $H_2O$  and det. corrected  $A$  as in 19.062. Det. amt of acetone in 250 mL vol. flask by ref. to std curve prepd as in 19.062.

In absence of purified acetone, g acetone/250 mL may be estd as  $C' = 2.5A/3.08$ , where  $C' =$  g acetone/250 mL, 2.5 = diln factor;  $A$  and 3.08 are defined in 19.062. Calc. to g acetone/100 mL sample. Deduct amt of free acetone as detd in 19.062, and multiply by 1.035 to obtain g isopropanol/100 mL sample.

**19.064 Glycerol—Official Final Action**

Proceed as in 11.010★, 12th ed., or 11.011★, 12th ed., selecting method according to amt of sugar present. Use sample contg 0.1–0.4 g glycerol.

**Oils of Lemon and Orange in Extracts****19.065 By Polarization (22)—Official Final Action**

Without dilg, polarize sample at 20° in 200 mm tube. Divide reading in °S, 31.020(a), by 3.2 for lemon ext and by 5.2 for orange ext. In absence of other optically active substances, result will be % oil by vol. If sucrose is present, det. as in 19.077 and correct reading accordingly. To obtain % oil by wt from % by vol., multiply vol. % by 0.86 for lemon exts, and by 0.85 for orange exts, and divide results by sp gr of original ext.

**19.066 By Precipitation (23)—Official Final Action**

Pipet 20 mL sample into Babcock milk bottle, 16.060(a). Add 1 mL HCl (1+1), then 25–28 mL  $H_2O$  previously warmed to 60°. Mix, and let stand 5 min in  $H_2O$  at 60°. Centrf. 5 min, fill bottle with warm  $H_2O$  to bring oil into graduated neck of flask, again centrf. 2 min, and place flask in  $H_2O$  at 60° few min. Note % oil by vol. If >2% oil is present, add 0.4% to % oil noted to correct for solubility of oil. If <2% but >1% is present, add 0.3% for this correction. To obtain % oil by wt from % by vol., multiply vol. % by 0.86 for lemon exts, and by 0.85 for orange exts, and divide result by sp gr of original ext.

**19.067 By Precipitation in Presence of Mineral Oil—Official First Action**

Proceed as in 19.126.

**Oils of Lemon, Orange, or Lime in Oil Base Flavors By Steam Distillation (24)—Official Final Action****19.068 Apparatus**

(a) **Steam generator filled with  $H_2O$ .**—Oil can holding 1 gal. (3.8 L) will serve purpose.

(b) **Distillation flask.**—750 mL Kjeldahl flask with short neck; total ht ca 25 cm.

(c) **Spray tube.**—Glass tube connected to steam generator; with small perforated bulb at end of tube passing thru rubber stopper and reaching bottom of distn flask.

(d) **Bent glass tube.**—Approx. 8 mm diam. Connects distn flask to upright condenser. Shape of this tube allows vapor condensing in tube to return to distn flask.

(e) **Liebig condenser.**—With 500 mm  $H_2O$  jacket.

(f) **Wilson receiving flask.**—(Fig. 19.01.) Babcock test bottle shape with graduated neck but of 250 mL capacity and with vertical glass outlet tube sealed on near bottom. Upper end of outlet tube is turned down. Neck may consist of portion of buret graduated from 0 to 25 mL with flared top. Outlet tube is ca 3 mm diam.; end is at such ht that when flask is filled with  $H_2O$ , meniscus in neck will be between 0 and 1 mL marks.

★ Surplus method—see inside front cover.

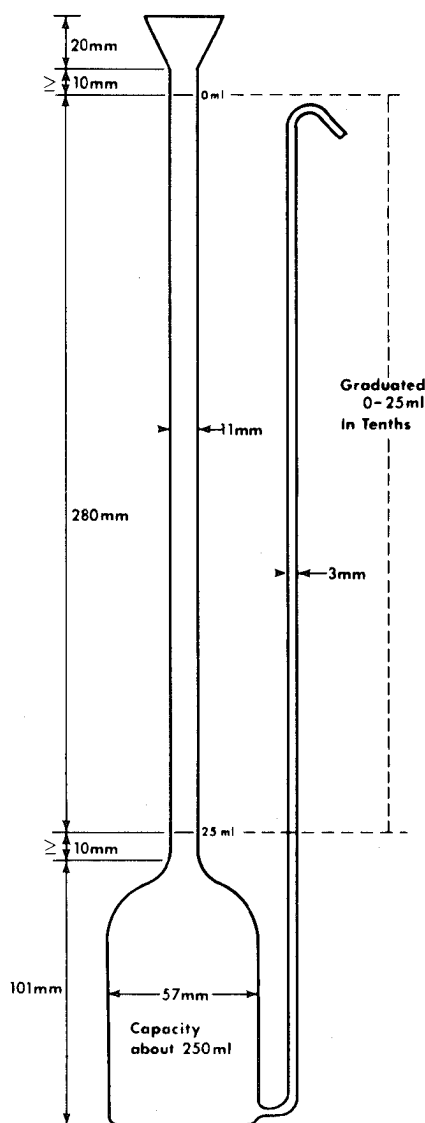

FIG. 19:01—Wilson flask

**19.069****Determination**

Measure 100 mL sample in graduate and transfer to distn flask. Immerse flask in  $H_2O$  bath and connect to condenser with the bent glass tube. Fill receiving flask with  $H_2O$  and so place under condenser that end of condenser is ca 1 cm above level of  $H_2O$  in receiving flask. Place 200 mL graduate under end of outlet tube to catch displaced liq. Heat  $H_2O$  bath to bp and pass steam thru sample until 200 mL liq. collects in graduate.

Disconnect app., let receiving flask stand 15 min, or until sepn of oil is complete, and read vol. of oil in flask. Calc. % (by vol.) of essential oil in sample by dividing reading by 0.90 for lemon oil in corn and cottonseed oils, 0.95 for orange oil in corn and cottonseed oils, and 0.78 for distd or expressed lime oil in corn and cottonseed oils. Where menstruum is mineral oil, subtract 0.3 mL from reading before dividing by factors 0.90, 0.95, and 0.78 for lemon oil, orange oil, and lime oil, resp.

**19.070 By Polarization (25)—Official First Action**

Polarize sample at  $20^\circ$  in 200 mm tube, making 5 readings. From av. of readings in  $^\circ S$ , **31.020(a)**, subtract: for corn oil  $+0.6^\circ$ ,

for cottonseed oil  $-0.3^\circ$ , for peanut oil  $+0.2^\circ$ , and for mineral oil  $+5.5^\circ$ , as correction for rotatory effect of menstruum. To obtain % by vol. of essential oil in mixt., divide corrected polariscopic reading so obtained by factor 3.4 for lemon oil in corn oil, 3.7 for lemon oil in cottonseed oil, 3.6 for lemon oil in peanut oil, 3.5 for lemon oil in mineral oil, 5.4 for orange oil in corn oil, 5.7 for orange oil in cottonseed oil, 5.6 for orange oil in mineral oil, 2.0 for lime oil in corn oil, 2.3 for lime oil in cottonseed oil, and 2.2 for lime oil in mineral oil.

**Total Aldehydes (26)—Official Final Action****19.071****Reagents**

(a) *Aldehyde-free alcohol*.—Let alcohol, contg 5 g *m*-phenylenediamine.2HCl/L, stand  $\geq 24$  hr with frequent shaking. (Nothing is gained by previous treatment with KOH.) Reflux at least 8 hr, longer if necessary; let stand overnight, and distil, rejecting first 10 and last 5 mL distillate. Store in dark, cool place in well filled bottles. (25 mL of this alcohol, on standing 20 min at  $14-16^\circ$  with 20 mL of the fuchsin-bisulfite soln, should develop only faint pink tinge. If stronger color develops, repeat above *m*-phenylenediamine treatment.) (Avoid skin and eye contact and breathing *m*-phenylenediamine dust.)

(b) *Fuchsin-bisulfite soln*.—Dissolve 0.5 g fuchsin in 250 mL  $H_2O$ , add aq. soln contg 16 g  $SO_2$ , let stand until colorless or nearly so, and dil. to 1 L with  $H_2O$ . Let stand 12 hr before use and keep in refrigerator. (This soln may deteriorate and should be reasonably fresh when used.)

(c) *Citral std soln*.—1 mg/mL. Weigh 0.5 g citral into 50 mL vol. flask, dil. to vol. with aldehyde-free alcohol at room temp., stopper flask, and mix by shaking. Dil. 10 mL of this soln with aldehyde-free alcohol to 100 mL in vol. flask, stopper, and mix.

**19.072****Determination**

Weigh ca 25 g sample in stoppered weighing flask, transfer to 50 mL vol. flask, and dil. to vol. at room temp. with aldehyde-free alcohol. Measure, at room temp., 2 mL (or other suitable vol.) of this soln into comparison tube. Add 25 mL aldehyde-free alcohol (previously cooled to  $14-16^\circ$ ), then 20 mL fuchsin-bisulfite soln (also cooled), and dil. to 50 mL with aldehyde-free alcohol. Mix thoroly, stopper, and keep 15 min at  $14-16^\circ$ .

Prep. std for comparison at same time and in same manner, using 2 mL std citral soln, and compare colors developed. Calc. amt of citral present and repeat detn, using amt sufficient to give sample ca strength of the std. From this result calc. amt of citral in sample. If comparisons are made in Nessler tubes, stds contg 1, 1.5, 2, 2.5, 3, 3.5, and 4 mg citral may be prepd and trial comparison made against these, final comparison being made with stds lying between 1.5 and 2.5 mg with 0.25 mg increments.

It is absolutely essential to keep reagents and comparison tubes at required temp.,  $14-16^\circ$ . If comparisons are made in a bath (possible only when bath is of glass), use stds within 25 min after adding fuchsin-bisulfite soln. Treat samples and stds identically.

**Citral (27)—Official Final Action**

(Lemon and orange exts)

**19.073****Reagent**

*Metaphenylenediamine hydrochloride-oxalic acid soln*.—(Caution: Avoid skin and eye contact and breathing *m*-phenylenediamine dust.) Remove interfering colored impurities in *m*-phenylenediamine.2HCl by digesting 3–5 g ca 5 min with ca 25 mL alcohol, decanting, and repeating 3 times. Dry crystals short time on steam bath. Dissolve 1 g in ca 45 mL 85% alcohol, dissolve 1 g crystd oxalic acid in 45 mL 85% alcohol, and pour

2 solns into 100 mL vol. flask. Add 2 or 3 g fuller's earth, dil. to vol. with 85% alcohol, mix, and filter thru double folded paper.

**19.074****Determination**

Weigh 25 g sample into 50 mL vol. flask, dil. to vol. with alcohol (95% by vol. for exts made with the oils; 50–95% by vol. for terpeneless exts), and mix. Pipet 2 mL or other suitable vol. of this soln into colorimeter tube, add 10 mL reagent, dil. to suitable vol., and compare resulting color with colors of set of stds contg known amts of citral std soln, **19.071(c)**.

**19.075 Total Solids—Official Final Action**

Proceed as in **9.022**, using 10 mL sample measured at 20°.

**19.076 Ash—Official Final Action**

Ignite residue from 10 mL sample as in **31.012** or **31.013**.

**19.077 Sucrose—Official Final Action**

Neutze normal wt of sample, evap. to dryness, wash several times with ether, dissolve in H<sub>2</sub>O, and proceed as in **31.025**, **31.026**, or **31.031**.

**LEMON AND ORANGE OILS****19.078 Specific Gravity—Official Final Action**

Det. sp gr at 20/20° with pycnometer as in **9.011**.

**19.079 Refractive Index—Official Final Action**

Use any std instrument, making reading at 20°. See **28.008**.

**19.080 Optical Rotation—Official Final Action**

Det. rotation at 20° with any std instrument, 50 mm tube, and Na light. State results in angular degrees on 100 mm basis. If instruments having sugar scale are used, reading for orange oils is above range of scale, but readings may be obtained by use of std levorotatory quartz plates, or by 25 mm tube. (True rotation cannot be obtained by dilg oil with alcohol and correcting rotation in proportion to diln.)

**19.081 Spectrophotometric Absorbance Characteristics (28) Official Final Action**

Accurately weigh 1 g (to nearest mg) sample in g-s weighing bottle. Dissolve in alcohol and transfer quant. to 100 mL vol. flask. Dil. to vol., mix well, and pipet 25 mL aliquot into another 100 mL vol. flask, dil. to vol. with alcohol, and mix well.

Det. *A* of the prepd soln in UV region from 260 to 375 nm with recording or manual (5 nm intervals) spectrophtr against alcohol in matched cell. (Readings at closer intervals (ca 3 nm) are preferred between 305 and 320 nm. Above 325 nm readings can be made at intervals of 10 nm.)

If instrument does not read directly in *A*, calc. from % *T* from tables or as  $A = 2 - \log \%T$ . Plot *A* against wavelength and draw smooth curve thru points.

Correct for background *A* as follows: Draw straight (base) line tangent to curve at point of min. *A* near 285 nm (285–295 nm) and at inflection point where curve levels off at ca 365 nm (365–370 nm). Drop vertical line *CD* from absorption peak (ca 315 nm) to baseline. Obtain length of vertical line *CD* in *A* units and record as corrected *A*.

**19.082 Physical Constants of 10 Per Cent Distillate (29) Official Final Action**

Place 50 mL sample in 3-bulb, 120 mL Ladenburg flask having

main bulb 6 cm diam. and condensing bulbs 3.5, 3, and 2.5 cm. Distance from bottom of flask to opening of side arm should be 20 cm. Distil oil at rate of 2 mL/min until 5 mL distills. Det. refractive index and optical rotation of this distillate as in **19.079** and **19.080**.

**Residue after Steam Distillation (30) Official Final Action****19.083****Apparatus**

Use steam distn assembly, Fig. **18:02**, except use 250 mL distg flask.

**19.084****Determination**

Add 50 mL H<sub>2</sub>O and 15 mL sample to 250 mL distn flask. Weigh 15 mL oil delivered by same pipet to obtain wt sample. Place steam inlet tube in flask, heat contents of flask just to bp, and connect inlet tube to steam. Adjust flame so that H<sub>2</sub>O level remains approx. const. Steam distil at const rate of ca 200 mL/hr until 100 mL H<sub>2</sub>O collects. Discontinue distn and let flask partially cool; then decant contents into 125–250 mL separator, and drain.

Rinse flask twice with 15 and 8 mL portions alcohol, warming if necessary to dissolve any residue. Pour alcohol rinsings into tared 150 mL beaker. Ext cooled liq. in separator with 25 and 20 mL portions CHCl<sub>3</sub>. (Add 1–2 drops HCl (1+2) to separator if there is any tendency for liqs to emulsify.) Add exts to tared beaker contg alcohol washings. Ext once with 25 mL ether and add this ext to others. Evap. exts carefully without spattering on cover of steam bath until ether and CHCl<sub>3</sub> are removed. Then evap. residual liq. on open steam bath. Let beaker remain on bath 15 min after odor of alcohol disappears. Remove, wipe outside of beaker with clean dry cloth, let cool, and weigh. Reheat, cool, and weigh until loss is <2 mg/5 min heating period. Calc. % residue by steam distn.

**Total Aldehydes—Official Final Action****19.085 Hiltner Method (27)**

Accurately weigh ca 2 g lemon oil or 8 g orange oil into 100 mL vol. flask, dil. to vol. with alcohol, and proceed as in **19.074**, using 2 mL dild soln for comparison.

**Kleber Method (31)**

(For orange oil)

**19.086****Reagent**

*Phenylhydrazine soln.*—Prep. 10% soln in absolute alcohol. Sufficiently pure phenylhydrazine can be obtained by distg com. product *in vacuo*, rejecting first portions coming over that contain NH<sub>3</sub>. (Caution: See **51.015**.)

**19.087****Determination**
